**Abstract.** The unfold/fold transformation system defined by Tamaki and Sato was meant for definite programs. It transforms a program into an equivalent one in the sense of both the least Herbrand model semantics and the Computed Answer Substitution semantics. Seki extended the method to normal programs and specialized it in order to preserve also the finite failure set. The resulting system is correct wrt nearly all the declarative semantics for normal programs. An exception is Fitting's model semantics. In this paper we consider a slight variation of Seki's method and we study its correctness wrt Fitting's semantics. We define an applicability condition for the fold operation and we show that it ensures the preservation of the considered semantics through the transformation.

## 1 Introduction

The unfold/fold transformation rules were introduced by Burstall and Darlington [8] for transforming clear, simple functional programs into equivalent, more efficient ones. The rules were early adapted to the field of logic programs both for program synthesis [10, 13] and for program specialization and optimization [2, 16]. Soon later, Tamaki and Sato [26] proposed an elegant framework for the transformation of logic programs based on unfold/fold rules.

The major requirement of a transformation system is its correctness: it should transform a program into an equivalent one. Tamaki and Sato's system was originally designed for definite programs and in this context a natural equivalence on programs is the one induced by the least Herbrand model semantics. In [26] it was shown that the system preserves such a semantics. Afterward, the system was proven to be correct wrt many other semantics: the computed answer substitution semantics [14], the Perfect model semantics [24], the Well-Founded semantics [25] and the Stable model semantics [23, 4].

In [24], Seki modified the method by restricting its applicability conditions. The system so defined enjoys all the semantic properties of Tamaki-Sato's, moreover,

it preserves the finite failure set of the original program [22] and it is correct wrt Kunen's semantics [21].

However, neither Tamaki-Sato's, nor Seki's system preserve the Fitting model semantics.

In this paper we consider a transformation schema which is similar yet slightly more restrictive to the one introduced by Seki [24] for normal programs. We study the effect of the transformation on the Fitting's semantics [11] and we individuate a sufficient condition for its preservation.

The difference between the method we propose and the one of Seki consists in the fact that here the operations have to be performed in a precise order. We believe that this order corresponds to the "natural" order in which the operations are usually carried out within a transformation sequence, and therefore that the restriction we impose is actually rather mild.

The structure of the paper is the following. In Section 2 we recall the definition of Fitting's operator. In Section 3 the transformation schema is defined and exemplified, and the applicability conditions for the fold operation are presented and discussed. Finally, in Section 4, we prove the correctness of the unfold/fold transformation wrt Fitting's semantics.

## 2 Preliminaries

We assume that the reader is familiar with the basic concepts of logic programming; throughout the paper we use the standard terminology of [17] and [1]. We consider *normal programs*, that is finite collections of *normal rules*,  $A \leftarrow L_1, \dots, L_m$ , where  $A$  is an atom and  $L_1, \dots, L_m$  are literals.  $B_P$  denotes the Herbrand base and  $Ground(P)$  the set of ground instances of clauses of a program  $P$ . We say that a clause is *definite* if the body contains only positive literals (atoms); a definite program is then a program consisting only of definite clauses. Symbols with a  $\sim$  on top denote tuples of objects, for instance  $\tilde{x}$  denotes a tuple of variables  $x_1, \dots, x_n$ , and  $\tilde{x} = \tilde{y}$  stands for  $x_1 = y_1 \wedge \dots \wedge x_n = y_n$ . We also adopt the usual logic programming notation that uses "," instead of  $\wedge$ , hence a conjunction of literals  $L_1 \wedge \dots \wedge L_n$  will be denoted by  $L_1, \dots, L_n$  or by  $\bar{L}$ .

**Three valued semantics for normal programs.** In this paper we refer to the usual Clark's completion definition,  $Comp(P)$ , [9] which consists of the completed definition of each predicate together with CET, Clark's Equality Theory, which is needed in order to interpret "=" correctly. It is well-known that, when considering *normal programs*, the two valued completion  $Comp(P)$  of a program  $P$  might be inconsistent and consequently have no model; moreover, when  $Comp(P)$  is consistent, it usually has more models, none of which can be considered the *least* (hence the preferred) one. Following [11], we avoid this problem by switching to a three-valued logic, where the truth tables of the connective are the ones given by Kleene [15]. When working with 3-valued logic, the same definition of completion applies, with the only difference that the connective  $\leftrightarrow$  is replaced with  $\Leftrightarrow$ , Lucasiwicz's operator of "having the same truth value". In this context, we have that a *three valued*

(or partial) interpretation, is a mapping from the ground atoms of the language  $\mathcal{L}$  into the set  $\{true, false, undefined\}$ .

**Definition 1.** Let  $\mathcal{L}$  be a language. A three valued (or partial)  $\mathcal{L}$ -interpretation,  $I$ , is a mapping from the ground atoms of  $\mathcal{L}$  into the set  $\{true, false, undefined\}$ .  $\square$

A partial interpretation  $I$  is represented by an ordered couple,  $(T, F)$ , of disjoint sets of ground atoms. The atoms in  $T$  (resp.  $F$ ) are considered to be *true* (resp. *false*) in  $I$ .  $T$  is the positive part of  $I$  and is denoted by  $I^+$ ; equivalently  $F$  is denoted by  $I^-$ . Atoms which do not appear in either set are considered to be *undefined*.

If  $I$  and  $J$  are two partial  $\mathcal{L}$ -interpretations, then  $I \cap J$  is the three valued  $\mathcal{L}$ -interpretation given by  $(I^+ \cap J^+, I^- \cap J^-)$ ,  $I \cup J$  is the three valued  $\mathcal{L}$ -interpretation given by  $(I^+ \cup J^+, I^- \cup J^-)$  and we say that  $I \subseteq J$  iff  $I = I \cap J$ , that is, iff  $I^+ \subseteq J^+$  and  $I^- \subseteq J^-$ . The set of all  $\mathcal{L}$ -interpretations is then a complete lattice. In the sequel we refer to a fixed but unspecified language  $\mathcal{L}$  that we assume contains all the functions symbols and the predicate symbols of the programs that we consider, consequently we will omit the  $\mathcal{L}$  prefix and speak of “interpretations” rather than of “ $\mathcal{L}$ -interpretations”.

We now give a definition of Fitting’s operator [11]. We denote by  $Var(E)$  the set of all the variables in an expression  $E$  and we write  $\exists y B\theta$  as a shorthand for  $(\exists y B)\theta$ , that is, unless explicitly stated, the quantification applies always before the substitution.

**Definition 2.** Let  $P$  be a normal program, and  $I$  a three valued interpretation.  $\Phi_P(I)$  is the three valued interpretation defined as follows:

- A ground atom  $A$  is *true* in  $\Phi_P(I)$   
iff there exists a clause  $c : B \leftarrow \tilde{L}$ . in  $P$  whose head unifies with  $A$ ,  $\theta = mgu(A, B)$ , and  $\exists \tilde{w} \tilde{\theta}$  is *true* in  $I$ , where  $\tilde{w}$  is the set of local variables of  $c$ ,  $\tilde{w} = Var(\tilde{L}) \setminus Var(B)$ .
- A ground atom  $A$  is *false* in  $\Phi_P(I)$   
iff for all clauses  $c : B \leftarrow \tilde{L}$  in  $P$  for which there exists  $\theta = mgu(A, B)$  we have that  $\exists \tilde{w} \tilde{\theta}$  is *false* in  $I$ , where  $\tilde{w}$  is the set of local variables of  $c$ ,  $\tilde{w} = Var(\tilde{L}) \setminus Var(B)$ .  $\square$

Recall that a *Herbrand* model is a model whose universe is given by the set of  $\mathcal{L}$ -terms.

$\Phi_P$  is a monotonic operator, that is  $I \subseteq J$  implies  $\Phi_P(I) \subseteq \Phi_P(J)$ , and characterizes the three valued semantics of  $Comp(P)$ , in fact Fitting, in [11] shows that the three-valued Herbrand models of  $Comp(P)$  are exactly the fixpoints of  $\Phi_P$ ; it follows that any program has a *least* (wrt.  $\subseteq$ ) three-valued Herbrand model, which coincides with the least fixpoint of  $\Phi_P$ . This model is usually referred to as Fitting’s model.

**Definition 3.** Let  $P$  be a program, *Fitting’s model* of  $P$ ,  $Fit(P)$ , is the least three valued Herbrand model of  $Comp(P)$ .  $\square$

We adopt the standard notation:  $\Phi_P^{\uparrow 0}$  is the interpretation that maps every ground atom into the value *undefined*,  $\Phi_P^{\uparrow \alpha+1} = \Phi_P(\Phi_P^{\uparrow \alpha})$ ,  $\Phi_P^{\uparrow \alpha} = \bigcup_{\delta < \alpha} \Phi_P^{\uparrow \delta}$ , when  $\alpha$  is a limit ordinal. From the monotonicity of  $\Phi_P$  follows that its Kleene's sequence is monotonically increasing and it converges to its least fixpoint. Hence there always exists an ordinal  $\alpha$  such that  $lfp(\Phi_P) = \Phi_P^{\uparrow \alpha}$ . Since  $\Phi_P$  is monotone but not continuous,  $\alpha$  could be greater than  $\omega$ .

**Theorem 4 [11].** *Let  $P$  be a program, then, for some ordinal  $\alpha$ ,*

$$- \text{Fit}(P) = \Phi_P^{\uparrow \alpha}$$

□

### 3 Unfold/fold transformations

#### 3.1 Introduction

Unfold and fold are basic transformation rules but their definition may differ depending on the considered semantics.

Unfolding is the fundamental operation for partial evaluation [18] and consists in applying a resolution step to the considered atom in all possible ways. Usually, it is applied only to positive literals (an exception is [3]).

Folding is the inverse of unfolding when one single unfolding is possible. Syntactically, it consists in substituting a literal  $L$  for an equivalent conjunction of literals  $\bar{K}$  in the body of a clause  $c$ . This operation is used to simplify unfolded clauses and to detect implicit recursive definitions. In order to preserve the declarative semantics of logic programs, its application must be restricted by some, semantic dependent, conditions. Therefore, the various proposals mainly differ in the choice of such conditions. They can be either a constraint on how to sequentialize the operations while transforming the program [26, 24], or they can be expressed only in terms of (semantic) properties of the program, independently from its transformation history [5, 19]. For normal programs different definitions for folding in a particular transformation sequence are given in [24, 23, 12].

#### 3.2 A four step transformation schema

In this section we introduce the *unfold/fold transformation schema*. All definitions are given modulo reordering of the bodies of the clauses and standardization apart is always assumed.

First we define the unfolding operation, which is basic to all the transformation systems.

**Definition 5 Unfold.** Let  $cl : A \leftarrow \bar{L}, H$ . be a clause of a normal program  $P$ , where  $H$  is an atom. Let  $\{H_1 \leftarrow \bar{B}_1, \dots, H_n \leftarrow \bar{B}_n\}$  be the set of clauses of  $P$  whose heads unify with  $H$ , by mgu's  $\{\theta_1, \dots, \theta_n\}$ .

- *unfolding an atom  $H$  in  $cl$*  consists of substituting  $cl$  with  $\{cl'_1, \dots, cl'_n\}$ , where, for each  $i$ ,  $cl'_i = (A \leftarrow \bar{L}, \bar{B}_i)\theta_i$ .

$$\text{unfold}(P, cl, H) \stackrel{\text{def}}{=} P \setminus \{cl\} \cup \{cl'_1, \dots, cl'_n\}.$$

□

Let  $P$  be a normal program. A *four step transformation schema* starting in the program  $P$  consists of the following steps:

**Step 1. Introduction of new definitions.** We add to the program  $P$  the set of clauses  $D_{\text{def}} = \{c_i : H_i \leftarrow \tilde{B}_i\}$ , where the predicate symbol of each  $H_i$  is *new*, that is, it does not occur in  $P$ . On the other hand, we require that the predicate symbols found in each  $\tilde{B}_i$  are defined in  $P$ , and therefore are not *new*. The result of this operation is then

$$- P_1 = P \cup D_{\text{def}} \quad \square$$

*Example 1 (min-max, part 1).* Let  $P$  be the following program

$$\begin{aligned}
 P = \{ & \min([X], X). \\
 & \min([X|Xs], Y) \leftarrow \min(Xs, Z), \text{inf}(X, Z, Y). \\
 & \max([X], X). \\
 & \max([X|Xs], Y) \leftarrow \max(Xs, Z), \text{sup}(X, Z, Y). \\
 & \text{inf}(X, Y, X) \leftarrow X \leq Y. \\
 & \text{inf}(X, Y, Y) \leftarrow \neg(X \leq Y). \\
 & \text{sup}(X, Y, Y) \leftarrow X \leq Y. \\
 & \text{sup}(X, Y, X) \leftarrow \neg(X \leq Y). \\
 c_1 : \text{med}(Xs, Med) & \leftarrow \min(Xs, Min), \\
 & \max(Xs, Max), \\
 & \text{Med is } (Min + Max)/2. \quad \}
 \end{aligned}$$

here  $\text{med}(Xs, Med)$  reports in  $Med$  the average between the minimum and the maximum of the values in the list  $Xs$ .

We may notice that the definition of  $\text{med}(Xs, Med)$  traverses the list  $Xs$  twice. This is obviously a source of inefficiency. In order to fix this problem via an unfold/fold transformation, we first have to introduce a new predicate  $\text{minmax}$ . Let us then add to program  $P$  the following new definition:

$$D_{\text{def}} = \{c_2 : \text{minmax}(Xs, Min, Max) \leftarrow \min(Xs, Min), \max(Xs, Max). \} \quad \square$$

**Step 2. Unfolding in  $D_{\text{def}}$ .** We transform  $D_{\text{def}}$  into  $D_{\text{unf}}$  by unfolding some of its clauses. The clauses of  $P$  are therefore used as unfolding clauses. This process can be iterated several times and usually ends when all the clauses that we want to fold have been obtained; the result of this operation is

$$- P_2 = P \cup D_{\text{unf}} \quad \square$$

*Example 1 (min-max, part 2).* We can now unfold the atom  $\text{min}(Xs, Min)$  in the body of  $c_2$ , the result is

$$\begin{aligned}
 c_3 : \text{minmax}([X], X, Max) & \leftarrow \max([X], Max). \\
 c_4 : \text{minmax}([X|Xs], Min, Max) & \leftarrow \min(Xs, Y), \\
 & \text{inf}(X, Y, Min), \\
 & \max([X|Xs], Max).
 \end{aligned}$$

In the bodies of both clauses we can then unfold predicate  $\text{max}$ . Each clause generates two clauses.

$$\begin{aligned}
c_5 &: \text{minmax}([X], X, X). \\
c_6 &: \text{minmax}([X], X, \text{Max}) \leftarrow \text{max}([], Z), \text{sup}(Z, X, \text{Max}). \\
c_7 &: \text{minmax}([X], \text{Min}, X) \leftarrow \text{min}([], Y), \text{inf}(X, Y, \text{Min}). \\
c_8 &: \text{minmax}([X|Xs], \text{Min}, \text{Max}) \leftarrow \text{min}(Xs, Y), \\
&\quad \text{inf}(X, Y, \text{Min}), \\
&\quad \text{max}(Xs, Z), \\
&\quad \text{sup}(X, Z, \text{Max}).
\end{aligned}$$

Clauses  $c_6$  and  $c_7$  can then be eliminated by unfolding respectively the atoms  $\text{max}([], Z)$  and  $\text{min}([], Y)$ .  $D_{\text{unf}}$  consists then of the following clauses.

$$\begin{aligned}
c_5 &: \text{minmax}([X], X, X). \\
c_8 &: \text{minmax}([X|Xs], \text{Min}, \text{Max}) \leftarrow \text{min}(Xs, Y), \\
&\quad \text{inf}(X, Y, \text{Min}), \\
&\quad \text{max}(Xs, Z), \\
&\quad \text{sup}(X, Z, \text{Max}).
\end{aligned}$$

Still,  $\text{minmax}$  traverses the list  $Xs$  twice; but now we can apply a *recursive folding* operation.  $\square$

**Step 3. Recursive folding.** Let  $c_i : H_i \leftarrow \tilde{B}_i$  be one of the clauses of  $D_{\text{def}}$ , which was introduced in *Step 1*, and  $cl : A \leftarrow \tilde{B}', \tilde{S}$  be (a renaming of) a clause in  $D_{\text{unf}}$ . If there exists a substitution  $\theta$ ,  $\text{Dom}(\theta) = \text{Var}(c_i)$  such that

- (a)  $\tilde{B}' = \tilde{B}_i\theta$ ;
- (b)  $\theta$  does not bind the local variables of  $c_i$ , that is for any  $x, y \in \text{Var}(\tilde{B}_i) \setminus \text{Var}(\tilde{H}_i)$  the following three conditions hold
  - $x\theta$  is a variable;
  - $x\theta$  does not appear in  $A, \tilde{S}, H_i\theta$ ;
  - if  $x \neq y$  then  $x\theta \neq y\theta$ ;
- (c)  $c_i$  is the only clause of  $D_{\text{def}}$  whose head unifies with  $H_i\theta$ ;
- (d) all the literals of  $\tilde{B}'$  are the result of a previous unfolding.

then we can fold  $H_i\theta$  in  $cl$ , obtaining  $cl' : A \leftarrow H_i\theta, \tilde{S}$ . This operation can be performed on several conjunctions simultaneously, even on the same clause. The result is that  $D_{\text{unf}}$  is transformed into  $D_{\text{fold}}$  and hence

$$- P_3 = P \cup D_{\text{fold}} \quad \square$$

*Example 1 (min-max, part 3).* We can now fold  $\text{min}(Xs, Y), \text{max}(Xs, Z)$  in the body of  $c_8$ . The resulting program  $D_{\text{fold}}$  consists of the following clauses

$$\begin{aligned}
c_5 &: \text{minmax}([X], X, X). \\
c_9 &: \text{minmax}([X|Xs], \text{Min}, \text{Max}) \leftarrow \text{minmax}(Xs, Y, Z), \\
&\quad \text{inf}(X, Y, \text{Min}), \\
&\quad \text{sup}(X, Z, \text{Max}).
\end{aligned}$$

$\text{minmax}(Xs, \text{Min}, \text{Max})$  has now a recursive definition and needs to traverse the list  $Xs$  only once. In order to let the definition of  $\text{med}$  enjoy of this improvement, we need to *propagate* predicate  $\text{minmax}$  inside its body.  $\square$

finite failure set [24], the Perfect model semantics for stratified programs [24], the Well-Founded semantics [25], the Stable model semantics [23, 4].

However, as it is, the schema suffers of the same problems of the sequence, i.e., Fitting's Models is not preserved. This is shown by the following example.

*Example 2.* Let  $P_1 = P \cup D_{\text{def}}$ , where  $P$  and  $D_{\text{def}}$  are the following programs

$$\begin{array}{l} D_{\text{def}} = \{ p \quad \leftarrow q(X). \quad \} \\ P \quad = \{ q(s(X)) \leftarrow q(X), t(0). \\ \quad \quad \quad t(0). \quad \quad \quad \} \end{array}$$

As we fix a language  $\mathcal{L}$  that contains the constant 0 and the function  $s/1$ , we have that  $\exists X q(X)$  is *false* in  $\text{Fit}(P_1)$ , consequently,  $p$  is also *false* in  $\text{Fit}(P_1)$ . Now let us unfold  $q(X)$  in the body of the clause in  $D_{\text{def}}$ ; the resulting program is the following.  $P_2 = P \cup D_{\text{unf}}$ , where

$$\begin{array}{l} D_{\text{unf}} = \{ p \quad \leftarrow q(Y), t(0). \quad \} \\ P \quad = \{ q(s(X)) \leftarrow q(X), t(0). \\ \quad \quad \quad t(0). \quad \quad \quad \} \end{array}$$

We can now fold  $q(Y)$  in the body of the clause of  $D_{\text{unf}}$ , the resulting program is  $P_3 = P \cup D_{\text{fold}}$ , where

$$\begin{array}{l} D_{\text{fold}} = \{ p \quad \leftarrow p, t(0). \quad \} \\ P \quad = \{ q(s(X)) \leftarrow q(X), t(0). \\ \quad \quad \quad t(0). \quad \quad \quad \} \end{array}$$

Now we have that  $p$  is *undefined* in the Fitting model of  $P_3$ . □

So, in order for the transformation to preserve Fitting's model of the original program, we need some further applicability conditions. Therefore the following.

**Theorem 6 Correctness.** *Let  $P_1, \dots, P_4$  be a sequence of programs obtained applying the transformation schema to program  $P$ . Let also  $D_{\text{def}} = \{H_i \leftarrow \tilde{B}_i\}$  be the set of clauses introduced in Step 1, and, for each  $i$ ,  $\tilde{w}_i$  be the set of local variables of  $c_i$ :  $\tilde{w}_i = \text{Var}(\tilde{B}_i) \setminus \text{Var}(H_i)$ . If each  $c_i$  in  $D_{\text{def}}$  satisfies the following condition:*

**A** *each time that  $\exists \tilde{w}_i \tilde{B}_i \theta$  is false in some  $\Phi_{P_1}^{\uparrow \beta}$ , then there exists a non-limit ordinal  $\alpha \leq \beta$  such that  $\exists \tilde{w}_i \tilde{B}_i \theta$  is false in  $\Phi_{P_1}^{\uparrow \alpha}$*

*Then  $\text{Fit}(P_1) = \text{Fit}(P_2) = \text{Fit}(P_3) = \text{Fit}(P_4)$ .*

**Proof.** The proof is given in the subsequent Section 4. □

**On condition A.** Condition A is in general undecidable, it is therefore important to provide some other decidable sufficient conditions. For this, in the rest of this Section, we adopt the following notation:

-  $D_{\text{def}} = \{c_i : H_i \leftarrow \tilde{B}_i\}$  is the set of clauses introduced in Step 1, and, for each  $i$ ,

-  $\tilde{w}_i = \text{Var}(\tilde{B}_i) \setminus \text{Var}(H_i)$  is the set of local variables of  $c_i$ .

First, it is easy to check that if  $c_i$  has no local variables, then it satisfies **A**.

**Proposition 7.** *If  $\tilde{w}_i = \emptyset$  then  $c_i$  satisfies **A**.*

**Proof.** It follows at once from the definition of Fitting's operator.  $\square$

This condition, though simple, is met by most of the examples found in the literature; if we are allowed an informal "statistics", of all the papers cited in our bibliography, seven contain practical examples in clausal form which can be assimilated to our method ([6, 14, 20, 22, 24, 25, 26]), and of them, only two contain examples where the "introduced" clause contains local variables ([14, 20]). Our Example 1 satisfies the condition as well.

Nevertheless Proposition 7 can easily be improved. First let us consider the following Example<sup>4</sup>.

*Example 3.* Let  $P_1 = P \cup D_{\text{def}}$ , where  $P$  and  $D_{\text{def}}$  are the following programs

$$\begin{aligned} D_{\text{def}} &= \{ c_0 : br(X, Y) \leftarrow reach(X, Z), reach(Y, Z). \} \\ P &= \{ \quad reach(X, Y) \leftarrow arc(X, Y). \\ &\quad reach(X, Y) \leftarrow arc(X, Z), reach(Z, Y). \quad \} \cup DB \end{aligned}$$

Where  $DB$  is any set of ground unit clauses defining predicate  $arc$ .  $reach(X, Y)$  holds iff there exists a path starting from node  $X$  and ending in node  $Y$ , while  $br(X, Y)$  holds iff there exists a node  $Z$  which is reachable both from node  $X$  and node  $Y$ .  $\square$

In this Example the definition of predicate  $br$  can be specialized and made recursive via an unfold/fold transformation. Despite the fact that clause  $c_0$  contains the local variable  $Z$ , it is easy to see that **A** is satisfied. This is due to the fact that  $P$  is actually a DATALOG (function-free) program.

We now show that if (a part of) the original program  $P$  is function-free (or recursion-free) then **A** is always satisfied.

Let us first introduce the following notation. Let  $p, q$  be predicates, we say that  $p$  *refers to*  $q$  in program  $P$  if there is a clause of  $P$  with  $p$  in its head and  $q$  in its body. The *depends on* relation is the reflexive and transitive closure of *refers to*. Let  $\tilde{L}$  be a conjunction of literals, by  $P|_{\tilde{L}}$  we denote the set of clauses of  $P$  that define the predicates which the predicates in  $\tilde{L}$  depend on. We say that a program is *recursion-free* if there is no chain  $p_1, \dots, p_k$  of predicate symbols such that  $p_i$  refers to  $p_{i+1}$  and  $p_k = p_1$ . With an abuse of notation, we also call a program *function-free* if the only terms occurring in it are either ground or variables.

We can now state the following.

**Proposition 8.** *For each index  $i$ , and each  $w \in \tilde{w}_i$ , let us denote by  $\tilde{L}_w$  the subset of  $\tilde{B}_i$  formed by those literals where  $w$  occurs. If for every  $\tilde{L}_w$ , one of the following two conditions holds:*

<sup>4</sup> The example is actually a modification of Example 2.1.1 in [22]

- (a)  $P_1|_{\tilde{L}_w}$  is recursion-free, or  
 (b)  $P_1|_{\tilde{L}_w}$  is function-free;

then each  $c_i$  satisfies **A**.

**Proof.** First we need the following Observation.

*Observation 9* Let  $Q$  be a function-free or a recursion-free program, then for some integer  $k$ ,  $\text{Fit}(Q) = \Phi_Q^{\uparrow k}$

*Proof.* Straightforward □

Now fix an index  $i$ , and let  $\tilde{w}_i = w_1, \dots, w_m$ , and let  $\tilde{M}$  be the subset of  $\tilde{B}_i$  consisting of those literals that do not contain any of the variables in  $\tilde{w}_i$ . It is immediate that, for any ordinal  $\alpha$ , and for any substitution  $\theta$

$$\Phi_{P_1}^{\uparrow \alpha} \models \exists \tilde{w}_i \tilde{B}_i \theta \text{ iff } \Phi_{P_1}^{\uparrow \alpha} \models \exists w_1 \tilde{L}_{w_1} \theta \wedge \dots \wedge \exists w_m \tilde{L}_{w_m} \theta \wedge \tilde{M} \theta \quad (1)$$

Now suppose that, for some ordinal  $\alpha$ , and substitution  $\theta$ ,  $\exists \tilde{w}_i \tilde{B}_i \theta$  is false in  $\Phi_{P_1}^{\uparrow \alpha}$ . By (1), either (i)  $\tilde{M} \theta$  is false in  $\Phi_{P_1}^{\uparrow \alpha}$ , or (ii) there exists an  $i$  such that  $\exists w_i \tilde{L}_{w_i} \theta$  is false in  $\Phi_{P_1}^{\uparrow \alpha}$ ; we treat the two cases separately.

(i),  $\tilde{M} \theta$  is false in  $\Phi_{P_1}^{\uparrow \alpha}$ , then, by the definition of  $\Phi_{P_1}$ , there exists a non-limit ordinal  $\beta \leq \alpha$  such that  $\tilde{M} \theta$  is false in  $\Phi_{P_1}^{\uparrow \beta}$ , and, by (1),  $\exists \tilde{w}_i \tilde{B}_i \theta$  is false in  $\Phi_{P_1}^{\uparrow \beta}$ .

(ii),  $\exists w_i \tilde{L}_{w_i} \theta$  is false in  $\Phi_{P_1}^{\uparrow \alpha}$ , since  $P_1|_{\tilde{L}_{w_i}}$  is function or recursion-free, by Observation 9 there exists an integer  $k$  such that  $\exists w_i \tilde{L}_{w_i} \theta$  is false in  $\Phi_{P_1}^{\uparrow k}$ ; again, by (1),  $\exists \tilde{w}_i \tilde{B}_i \theta$  is false in  $\Phi_{P_1}^{\uparrow k}$ .

So, in any case, there exists a non-limit ordinal  $\beta \leq \alpha$  such that  $\exists \tilde{w}_i \tilde{B}_i \theta$  is false in  $\Phi_{P_1}^{\uparrow \beta}$ . Since this holds for any index  $i$ , the thesis follows. □

**Checking A “a posteriori”.** We now show that condition **A** holds in  $P_0$  iff it holds in any program of the unfold part of the transformation sequence. This gives us the opportunity of providing further sufficient conditions.

First let us restate **A** as follows:

**A’:** For each substitution  $\theta$  and non-limit ordinal  $\beta$ , if  $H_i \theta$  is false in  $\Phi_{P_1}^{\uparrow \beta+1}$ , then  $H_i \theta$  is false in  $\Phi_{P_1}^{\uparrow \beta}$  as well.

Now, let  $P'_1$  be a program which is obtained from  $P_1$  by applying some unfolding transformation. It is easy to see<sup>5</sup> that  $H_i$  satisfies **A’** in  $P_1$  iff  $H_i$  satisfies **A’** in  $P'_1$ . So the advantage of **A’** over **A** is that it can be checked a posteriori at any time during the unfolding part of the transformation. So Proposition 8 can be restated as follows.

**Proposition 10.** Let  $P'_1$  be a program obtained from  $P_1$  by (repeatedly) applying the unfolding operation. Let  $D'_{\text{def}}$  be the subset of  $P'$  corresponding to  $D_{\text{def}}$  in  $P$ . If for each clause  $c$  of  $D'_{\text{def}}$ , and for every variable  $y$ , local to the body of  $c$

<sup>5</sup> This is a direct consequence of Lemma 11, which is given in the next Section

- $P'_1|_{\tilde{L}_y}$  is recursion-free or function-free,  
where  $\tilde{L}_y$  denotes the subset of the body of  $c$  consisting of those literals where  $y$  occurs;

then each  $c_i$  satisfies **A** in  $P_1$ .

**Proof.** It is a straightforward generalization of the proof of Proposition 8.  $\square$

## 4 Correctness of the transformation

The aim of this section is to prove the correctness of the transformation schema wrt Fitting's semantics, Theorem 6.

### 4.1 Correctness of the unfold operation

First we consider the unfold operation. To prove its correctness we need the following technical Lemma.

**Lemma 11.** *Let  $P'$  be the program obtained by unfolding an atom in a clause of program  $P$ . Then for each integer  $i$  and limit ordinal  $\beta$ ,*

- $\Phi_P^{1^i} \subseteq \Phi_{P'}^{1^i}$  and  $\Phi_{P'}^{1^i} \subseteq \Phi_P^{1^{2i}}$ ;
- $\Phi_P^{1^i}(\Phi_P^{1^\beta}) \subseteq \Phi_{P'}^{1^i}(\Phi_{P'}^{1^\beta})$  and  $\Phi_{P'}^{1^i}(\Phi_{P'}^{1^\beta}) \subseteq \Phi_P^{1^{2i}}(\Phi_P^{1^\beta})$ .

**Proof.** The proof is given in [7].  $\square$

This brings us to a preliminary conclusion.

**Corollary 12 Correctness of the unfold operation.** *Let  $P'$  be the result of unfolding an atom of a clause in  $P$ . Then*

- $Fit(P) = Fit(P')$   $\square$

It should be mentioned that, because of the particular structure of the transformation sequence, here we never use self-unfoldings (that is, unfoldings in which the same clause is both the unfolded clause and one of the unfolding ones). Consequently the correctness of *Step 2* follows also from a result of Gardner and Shepherdson [12, Theorem 4.1] which states that if the program  $P'$  is obtained from  $P$  by unfolding (but not self-unfolding), then  $Comp(P)$  and  $Comp(P')$  are logically equivalent theories<sup>6</sup>.

The following is a second, technical result on the consequences of an unfolding operation which will be needed in the sequel.

**Lemma 13.** *Let  $P$  be a normal program,  $cl : A \leftarrow \tilde{K}$ . be a definite, clause of  $P$ . Suppose also that  $cl$  is the only clause of  $P$  whose head unifies with  $A\theta$ . If  $P'$  is the program obtained by unfolding at least once all the atoms in  $\tilde{K}$ , then, for each non-limit ordinal  $\alpha$*

<sup>6</sup> In [12] this result is stated for the usual two-valued program's completion. By looking at the proof it is straightforward to check that it holds also for the three-valued case

– if  $A\theta$  is true (resp. false) in  $\Phi_P^{\uparrow\alpha+1}$  then  $A\theta$  is true (resp. false) in  $\Phi_{P'}^{\uparrow\alpha}$

**Proof.** Let us first give a simplified proof by considering the case when  $\tilde{K}$  consists of two atoms  $H, J$  and we perform a single unfolding on them; we will later consider the general case.

Let  $\{H_1 \leftarrow \tilde{B}_1, \dots, H_n \leftarrow \tilde{B}_n.\}$  be the set of clauses of  $P$  whose head unify with  $H$  via mgu's  $\phi_1, \dots, \phi_n$ , and let  $\{J_1 \leftarrow \tilde{C}_1, \dots, J_m \leftarrow \tilde{C}_m.\}$  be the set of clauses of  $P$  whose head unify with  $J$ . Unfolding  $H$  in  $cl$  and then  $J$  in the resulting clauses, will lead to the following program:

$$P' = P \setminus \{cl\} \cup \{d_{i,j} : (A \leftarrow \tilde{B}_i, \tilde{C}_j.)\theta_{i,j}\}$$

Where  $\theta_{i,j} = \text{mgu}(J\phi_i, J_j)$ . Here some of the clauses  $d_{i,j}$  may be missing due to the fact that  $J\phi_i$  and  $J_j$  may not unify, but this is of no relevance in the proof.

Note that the clauses  $d_{i,j}$  are the only clauses of  $P'$  whose head could possibly unify with  $A$ .

Let  $\tilde{y} = \text{Var}(H, J) \setminus \text{Var}(A)$  be the set of variables local to the body. We have to consider two cases.

a)  $A\theta$  is true in  $\Phi_P^{\uparrow\alpha+1}$ . By the definition of  $\Phi_P$ ,  $(\exists \tilde{y} H, J)\theta$  is true in  $\Phi_P^{\uparrow\alpha}$ . There has to be an extension  $\sigma$  of  $\theta$ ,  $\text{Dom}(\sigma) = \text{Dom}(\theta) \cup \tilde{y} = \text{Var}(A, H, J)$  such that  $(H, J)\sigma$  is true in  $\Phi_P^{\uparrow\alpha}$ . Let  $H_i \leftarrow \tilde{B}_i$  and  $J_j \leftarrow \tilde{C}_j$  be the clauses used to prove, respectively,  $H\sigma$  and  $J\sigma$ . Hence there exists a  $\tau$  such that  $\theta_{i,j}\tau|_{\text{Dom}(\sigma)} = \sigma$ ,  $H\sigma = H_i\theta_{i,j}\tau$ ,  $J\sigma = J_j\theta_{i,j}\tau$ , and  $(\tilde{B}_i, \tilde{C}_j)\theta_{i,j}\tau$  is true in  $\Phi_{P'}^{\uparrow\alpha-1}$ . By Lemma 11,  $\Phi_P^{\uparrow\alpha-1} \subseteq \Phi_{P'}^{\uparrow\alpha-1}$ , hence  $(\tilde{B}_i, \tilde{C}_j)\theta_{i,j}\tau$  is true in  $\Phi_{P'}^{\uparrow\alpha-1}$ . It follows that  $A\theta_{i,j}\tau = A\sigma = A\theta$  is true in  $\Phi_{P'}^{\uparrow\alpha}$ .

b)  $A\theta$  is false in  $\Phi_P^{\uparrow\alpha+1}$ . By the definition of  $\Phi_P$ ,  $(\exists \tilde{y} H, J)\theta$  is false in  $\Phi_P^{\uparrow\alpha}$ . Hence for all extensions  $\sigma$  of  $\theta$ , such that  $\text{Dom}(\sigma) = \text{Dom}(\theta) \cup \tilde{y} = \text{Var}(A, H, J)$ , we have that  $(H, J)\sigma$  is false in  $\Phi_P^{\uparrow\alpha}$ .

Hence for all such  $\sigma$ 's, and for all  $i, j$  and  $\tau$  such that  $\theta_{i,j}\tau|_{\text{Dom}(\sigma)} = \sigma$ ,  $H\sigma = H_i\theta_{i,j}\tau$ ,  $J\sigma = J_j\theta_{i,j}\tau$ , we have that  $(\tilde{B}_i, \tilde{C}_j)\theta_{i,j}\tau$  is false in  $\Phi_P^{\uparrow\alpha-1}$ . By Lemma 11,  $\Phi_P^{\uparrow\alpha-1} \subseteq \Phi_{P'}^{\uparrow\alpha-1}$ , hence  $(\tilde{B}_i, \tilde{C}_j)\theta_{i,j}\tau$  is false in  $\Phi_{P'}^{\uparrow\alpha-1}$ . Since the clauses  $d_{i,j}$  are the only ones that define  $A$  in  $P'$ , we have that  $A\theta_{i,j}\tau = A\sigma = A\theta$  is false in  $\Phi_{P'}^{\uparrow\alpha}$ .

Now to complete the proof, we have to observe two facts:

– First, that if we perform some further unfoldings on the resulting clauses, then we can only “speed up” the process of finding the truth value of  $A$ . In fact, by the same kind of reasoning used above, if  $A\theta$  is true in  $\Phi_{P'}^{\uparrow\alpha}$ , and  $P''$  is obtained from  $P'$  by unfolding some atoms in the bodies of the clauses  $d_{i,j}$ , then, for some  $\beta \leq \alpha$ ,  $A\theta$  is true in  $\Phi_{P''}^{\uparrow\beta}$ .

– Second, that if  $cl$  contains just one atom, or more than two atoms, then the exact same reasoning applies.  $\square$

## 4.2 The replacement operation

In order to prove the correctness of the unfold/fold transformation schema we will use (a simplified version of) the results in [6, 7] on the simultaneous replacement operation.

The replacement operation has been introduced by Tamaki and Sato in [26] for definite programs. Syntactically it consists in substituting a conjunction,  $\tilde{C}$ , of literals with another one,  $\tilde{D}$ , in the body of a clause.

Similarly, *simultaneous* replacement consists in substituting a set of conjunctions of literals  $\{\tilde{C}_1, \dots, \tilde{C}_n\}$ , with another corresponding set of conjunctions  $\{\tilde{D}_1, \dots, \tilde{D}_n\}$  in the bodies of the clauses of program  $P$ ; here each  $\tilde{C}_i$  represents a subset of the body of a clause of  $P$  and we assume that if  $i \neq j$  then  $\tilde{C}_i$  and  $\tilde{C}_j$  do not overlap, that is, they are either found in different clauses or they represent disjoint subsets of the same clause.

Note that the fact that each  $\tilde{C}_i$  may occur in the body of only one clause of  $P$  is not restrictive, as even if  $i \neq j$ ,  $\tilde{C}_i$  and  $\tilde{C}_j$  may actually represent identical literals.

We now give a simplified version of the *applicability conditions* introduced in [6, 7] in order to ensure the preservation of the semantics through the transformation. Such conditions depend on the semantics we associate to the program. Our first requirement is the semantic equivalence of the replacing and the replaced conjunctions of literals.

**Definition 14** *Equivalence of formulas.* Let  $E, F$  be first order formulas and  $P$  be a normal program.

- $F$  is equivalent to  $E$  wrt  $Fit(P)$ ,  $F \sim_P E$ , if for each ground substitution  $\theta$   $E\theta$  is true (resp. false) in  $Fit(P)$  iff  $F\theta$  is. □

Note that  $F \sim_P E$  iff  $Fit(P) \models \forall(F \Leftrightarrow E)$ .

*Example 4.* Let  $P$  be the program in Example 1. We have that

$$med(Xs, Med) \sim_P \exists X, Y \min(Xs, X) \wedge \max(Xs, Y) \wedge Med = (X + Y)/2 \quad \square$$

With many respects, and with some caution, two equivalent (conjunctions of) literals can be used interchangeably; for example, if  $q$  is a new predicate we want to give a definition to, and we know that  $A \sim_P B$  then defining  $q$  by introducing the new clause  $q \leftarrow A$  is, from Fitting's semantics viewpoint, equivalent to doing it by introducing  $q \leftarrow B$ .

Notice that the formula in Example 4 we had to specify  $X$  and  $Y$  as existentially quantified variables. When we want to replace the conjunction  $\tilde{C}$  with  $\tilde{D}$ , in the clause  $cl$  the first requirement of those applicability conditions is the equivalence of  $\exists \tilde{x} \tilde{C}$  and  $\exists \tilde{x} \tilde{D}$ , where  $\tilde{x}$  is a set of "local variables", that is, variables which appear in  $\tilde{C}$  and/or  $\tilde{D}$ , but which do not occur anywhere else in the clause that we are transforming. The equivalence is required as it would make no sense to replace  $\tilde{C}$  with something which has a different meaning. Unfortunately this is not enough, in fact we need the equivalence to hold also after the transformation. The equivalence can be destroyed when  $\tilde{D}$  depends on  $cl$ , in which case the operation may introduce an infinite loop.

In order to prove that no fatal loops are introduced, we make use of a further concept. Here we say that the (closed) formula  $G$  is *defined* in the interpretation  $I$ , if the truth value of  $G$  in  $I$  is not *undefined*.

**Definition 15 not-slower.** Let  $P$  be a normal program,  $E$  and  $F$  be first order formulas. Suppose that  $F \sim_P E$ . We say that

- $F$  is not-slower than  $E$  if for each ordinal  $\alpha$  and each ground substitution  $\theta$ : if  $E\theta$  is defined in  $\Phi_P^{1\alpha}$ , then  $F\theta$  is defined in  $\Phi_P^{1\alpha}$  as well.  $\square$

So  $F$  is not-slower than  $E$  if, for each  $\theta$ , computing the truth value of  $F\theta$  never requires more iterations than computing the one of  $E\theta$ . In a way we could then say that the definition of  $F$  is at least as efficient as the one of  $E$ .

The following Theorem shows that if the replacing conjunctions are equivalent to and not-slower than the replaced ones, then the replacement operation is correct.

**Theorem 16.** Let  $P'$  be a program obtained by simultaneously replacing the conjunctions  $\{\tilde{C}_1, \dots, \tilde{C}_n\}$  with  $\{\tilde{D}_1, \dots, \tilde{D}_n\}$  in the bodies of the clauses of  $P$ . If for each  $\tilde{C}_i$ , there exists a (possibly empty) set of variables  $\tilde{x}_i$  such that the following three conditions hold:

- (a) [locality of the variables in  $\tilde{x}_i$ ].  $\tilde{x}_i$  is a subset of the variables local to  $\tilde{C}_i$  and  $\tilde{D}_i$ , that is,  $\tilde{x}_i \subseteq \text{Var}(\tilde{C}_i) \cup \text{Var}(\tilde{D}_i)$  and the variables in  $\tilde{x}_i$  don't occur in  $\{\tilde{D}_1, \dots, \tilde{D}_{i-1}, \tilde{D}_{i+1}, \dots, \tilde{D}_n\}$  nor anywhere else in the clause where  $\tilde{C}_i$  is found.
- (b) [equivalence of the replacing and replaced parts].  $\exists \tilde{x}_i \tilde{D}_i \sim_P \exists \tilde{x}_i \tilde{C}_i$
- (c) [the  $D_i$ 's are not-slower than the  $C_i$ 's].  $\exists \tilde{x}_i \tilde{D}_i$  is not-slower than  $\exists \tilde{x}_i \tilde{C}_i$ .

then  $\text{Fit}(P) = \text{Fit}(P')$ .

**Proof.** This is a particular case of Corollary 3.16 in [7].  $\square$

A property we will need in the sequel is the following.

**Proposition 17.** Suppose that  $A \leftarrow \tilde{C}, \tilde{E}$  is a clause of  $P$  and that  $P'$  is obtained from  $P$  by replacing  $\tilde{C}$  with  $\tilde{D}$  in such a way that the conditions of Theorem 16 are satisfied (so that  $\text{Fit}(P) = \text{Fit}(P')$ ). Then

- Each time that  $A\theta$  is true (resp. false) in  $\Phi_P^{1\alpha}$  then  $A\theta$  is true (resp. false) in  $\Phi_{P'}^{1\alpha}$ .

**Proof.** This is a consequence of the fact that the replacing conjunction is not-slower than the replaced one. The formal proof is omitted here, it can be inferred by analyzing the proof of Theorem 3.15 in [7].  $\square$

Before we provide the proof of the correctness of the four step schema, we need to establish some further preliminary results. The first one states that the converse of **A** holds in any case.

**Proposition 18.** Each time that  $\exists \tilde{w} \tilde{B}\theta$  is true in some  $\Phi_{P_1}^{1\beta}$ , then there exists a non-limit ordinal  $\alpha \leq \beta$  such that  $\exists \tilde{w} \tilde{B}\theta$  is true in  $\Phi_{P_1}^{1\alpha}$ .

**Proof.** It follows at once from the definition of Fitting's operator.  $\square$

The following important transitive property holds:

**Proposition 19.** *Let  $P$  and  $P'$  be normal programs,  $E$  and  $F$  be first order formulas;*  
 – *If  $E \sim_P F$  and  $\text{Fit}(P) = \text{Fit}(P')$ , then  $E \sim_{P'} F$ .* □

Now we can provide the details of the proof.

### 4.3 Correctness of the four step schema

We now prove the correctness of the four step schema. For the sake of simplicity we restrict ourselves to the case in which *Step 1* introduces only one clause. The extension to the general case is straightforward.

Let  $P_1, \dots, P_4$  be the sequence of programs obtained via the four step schema:  $P_1$  is the initial program, i.e. the one that contains  $D_{\text{def}}$ .  $P_2$ ,  $P_3$  and  $P_4$ , are the programs obtained by applying steps *Step 2* through *Step 4*. In order to show that the Fitting's models of programs  $P_1, \dots, P_4$  coincide, we proceed as follows:

By the correctness of the unfolding operation, Corollary 12 we have that  $\text{Fit}(P_1) = \text{Fit}(P_2)$ .

We perform some further unfolding on some atoms of  $P_2$ , obtaining a new program that we will call  $P_{2u}$ , again by Corollary 12 we have that  $\text{Fit}(P_2) = \text{Fit}(P_{2u})$ ; then we produce a “parallel sequence” of programs  $P_{3u}, P_{4u}$  by applying the simultaneous replacement operation, miming, to some extent, the original transformation. By applying Theorem 16 we will show that  $\text{Fit}(P_{2u}) = \text{Fit}(P_{3u}) = \text{Fit}(P_{4u})$ .

Finally we show that programs  $P_{3u}$  and  $P_{4u}$  are obtainable respectively from  $P_3$  and  $P_4$  by appropriately applying the unfold operation, and hence, by Corollary 12, that  $\text{Fit}(P_3) = \text{Fit}(P_{3u})$  and that  $\text{Fit}(P_4) = \text{Fit}(P_{4u})$ . This will end the proof. Fig.1 illustrates both the original transformation and its parallel sequence.

**Initial program.** Let us establish some notation:  $P_1 \dots P_4$  are the programs obtained by applying the four step schema to program  $P$ , and  $c_0 : H \leftarrow \tilde{B}$ . is the (only) clause added to program  $P$  in *Step 1*. We also denote by  $\tilde{w}$  the set of the local variables of  $c_i$ ,  $\tilde{w} = \text{Var}(\tilde{B}) \setminus \text{Var}(H)$ . For the moment, let us make the following restriction:

– till the end of 4.3, we assume that  $\tilde{B}$  doesn't contain negative literals.

Later, in subsection 4.4, we will prove the general case.

A simple consequence of the fact that  $c_0$  is the only clause defining the predicate symbol of  $H$  is the following.

*Observation 20*

–  $H \sim_{P_1} \exists \tilde{w} \tilde{B}$ ; □

**$P_2$  and  $P_{2u}$ .**  $P_2$  is obtained by unfolding some of the atoms in  $\tilde{B}$ , so  $P_2 = P \cup \{A_i \leftarrow \tilde{U}_i, \tilde{N}_i\}$ , where the atoms in  $\tilde{N}_i$  are those that have not been unfolded during *Step 1* ( $N$  stands for Not unfolded, while  $U$  for Unfolded), so  $\tilde{N}_i$  is equal to a subset of an instance of  $\tilde{B}$  and each  $A_i$  is an instance of  $H$ . We obtain  $P_{2u}$  from  $P_2$  by further

unfolding all the atoms in each  $\tilde{N}_i$ . We denote by  $\{c_{i,j} : (A_i \leftarrow \tilde{U}_i)\gamma_{i,j}, \tilde{D}_{i,j}\}$  the set of clauses of  $P_{2u}$  obtained from clause  $c_i$  by unfolding the atoms in  $\tilde{N}_i$ . By the correctness of the unfolding operation, Corollary 12, we have that

$$Fit(P_1) = Fit(P_2) = Fit(P_{2u}) \quad (2)$$

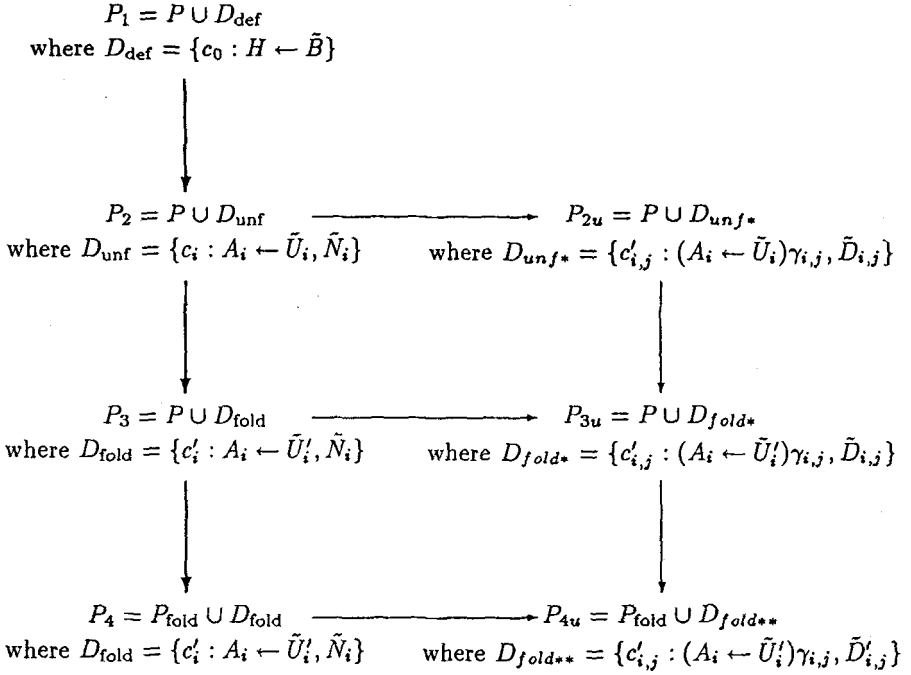

Fig. 1. Diagram of the transformation (left) together with the “parallel sequence” (right).

Moreover, the following properties hold:

*Observation 21*

- $H \sim_{P_{2u}} \exists \tilde{w} \tilde{B}$ ;
- $H$  is not-slower than  $\exists \tilde{w} \tilde{B}$  in  $P_{2u}$ .

*Proof.* From Observation 20 we have that  $H \sim_{P_1} \exists \tilde{w} \tilde{B}$ . The first statement follows then from (2) and Proposition 19. For the second, fix  $\theta$  and let  $\beta$  be the least ordinal such that  $\exists \tilde{w} \tilde{B}\theta$  is true (or false) in  $\Phi_{P_{2u}}^{\uparrow\beta}$ . The clauses defining the atoms in  $\tilde{B}$  are the same in  $P_1$ ,  $P_2$  and  $P_{2u}$ , so  $\exists \tilde{w} \tilde{B}$  is true (resp. false) in  $\Phi_{P_1}^{\uparrow\beta}$  as well. From

condition **A** and Proposition 18 we have that  $\beta$  is a non-limit ordinal. Hence, by the definition of  $\Phi$ ,  $H\theta$  is *true* (resp. *false*) in  $\Phi_{P_1}^{1\beta+1}$ , and, by Lemma 13  $H\theta$  is *true* (resp. *false*) in  $\Phi_{P_{3u}}^{1\beta}$ .  $\square$

$P_3$  and  $P_{3u}$ .  $P_{3u}$  is obtained from  $P_{2u}$  as follows.

Suppose that in *Step 2* we performed a recursive folding on the clause  $c_i$  :  $A_i \leftarrow \tilde{B}\theta, \tilde{R}_i, \tilde{N}_i$  of  $P_2$ , obtaining  $c'_i$  :  $A_i \leftarrow H\theta, \tilde{R}_i, \tilde{N}_i$  in  $P_3$ . In the diagram we denote by  $\tilde{U}'_i$  the conjunction of literals resulting from the application of the recursive folding on the conjunction  $\tilde{U}_i$  (so  $\tilde{U}_i = \tilde{B}\theta, \tilde{R}_i$  and  $\tilde{U}'_i = H\theta, \tilde{R}_i$ ).

On  $P_{2u}$  we then perform the following. In each of the clauses  $c_{i,j}$  we transform  $\tilde{U}_i\gamma_{i,j}$  into  $\tilde{U}'_i\gamma_{i,j}$  by replacing conjunctions of literals of the form  $\tilde{B}\theta\gamma_{i,j}$  with  $H\theta\gamma_{i,j}$  wherever needed; we call the resulting clauses  $c'_{i,j}$ . It is easy to see that if we unfold all the atoms in  $\tilde{N}_i$  in the body of clause  $c'_i$  in  $P_3$ , then the resulting clauses are exactly the  $c'_{i,j}$  in  $P_{3u}$ ; this is best shown by the diagram. Hence  $P_{3u}$  is obtainable from  $P_3$  by appropriately applying the unfolding operation. From Corollary 12 it follows that

$$Fit(P_3) = Fit(P_{3u}) \quad (3)$$

Now we show that  $Fit(P_{2u}) = Fit(P_{3u})$ . First we need the following.

**Proposition 22.** *Let  $Q$  be a program,  $A, B$  be atoms and  $\tilde{y}$  be a set of variables, such that  $A \sim_Q \exists \tilde{y} B$ . Suppose also that  $\eta$  is a renaming over  $\tilde{y}$  and that for each variable  $z$  that occurs in  $A$  or  $B$ , but not in  $\tilde{y}$ ,  $Var(z\eta) \cap Var(\tilde{y}\eta) = \emptyset$ . Then*

$$- A\eta \sim_Q \exists(\tilde{y}\eta) B\eta$$

**Proof.** Straightforward.  $\square$

Since  $\gamma_{i,j}$  results from unfolding the atoms in  $\tilde{N}_i$ , we have that  $Dom(\gamma_{i,j}) \cap Var(c_i) \subseteq Var(\tilde{N}_i)$ . Hence, by the conditions on  $\theta$  in *Step 2*,  $Dom(\gamma_{i,j}) \cap \tilde{w}\theta = \emptyset$  and  $\tilde{w}\theta\gamma_{i,j} = \tilde{w}\theta$ ; so  $\theta\gamma_{i,j}$  is a renaming over  $\tilde{w}$ , and the variables in  $\tilde{w}\theta\gamma_{i,j}$  do not occur anywhere else in  $c_{i,j}$ . From Observation 21 and Proposition 22 we have that

$$\begin{aligned} - H\theta\gamma_{i,j} &\sim_{P_{2u}} \exists(\tilde{w}\theta\gamma_{i,j}) \tilde{B}\theta\gamma_{i,j}; \\ - H\theta\gamma_{i,j} &\text{ is not-slower than } \exists(\tilde{w}\theta\gamma_{i,j}) \tilde{B}\theta\gamma_{i,j} \text{ in } P_{2u}. \end{aligned}$$

Since we obtained  $P_{3u}$  from  $P_{2u}$  by simultaneously replacing conjunctions (of the form)  $\tilde{B}\theta\gamma_{i,j}$  with  $H\theta\gamma_{i,j}$ , by Theorem 16

$$Fit(P_{2u}) = Fit(P_{3u}). \quad (4)$$

Moreover, the following properties hold:

*Observation 23*

$$\begin{aligned} - H &\sim_{P_{3u}} \exists \tilde{w} \tilde{B}; \\ - H &\text{ is not-slower than } \exists \tilde{w} \tilde{B} \text{ in } P_{3u}. \end{aligned}$$

*Proof.* The first statement follows from Observation 21, (4) and Proposition 19. For the second first note that going from  $P_{2u}$  to  $P_{3u}$  we have affected only clauses that define the predicate *new*, moreover no other predicates definition depends on these clauses, in particular the atoms in  $\tilde{B}$  are independent from them, hence, since  $H$  is not-slower than  $\exists \tilde{w} \tilde{B}$  in  $P_{2u}$ , the statement follows from Proposition 17.  $\square$

$P_4$  and  $P_{4u}$ .  $P_4$  is obtained from  $P_3$  by transforming some of the clauses of  $P$  of the form  $A \leftarrow \tilde{B}\theta, \tilde{E}$  into  $A \leftarrow H\theta, \tilde{E}$ .

Now we want to obtain  $P_{4u}$  from  $P_{3u}$  in such a way that  $P_{4u}$  is obtainable also from  $P_4$  by unfolding the atoms in the conjunctions  $\tilde{N}_i$ .

Let  $d : A \leftarrow \tilde{B}\theta, \tilde{E}$  be one of the clauses of  $P_3$  that are transformed in *Step 4*. First note that  $d$  belongs both to  $P_3$  and  $P_{3u}$ , in fact  $d$  was already present in the original program  $P$ , and never modified. We can then apply the same operations to the clauses of  $P_{3u}$ . Observe that for the conditions on  $\theta$  given in *Step 4*, and by *Observation 23* we have that

*Observation 24*

- $H\theta \sim_{P_{3u}} \exists(\tilde{w}\theta) \tilde{B}\theta$
- $H\theta$  is not-slower than  $\exists(\tilde{w}\theta) \tilde{B}\theta$  in  $P_{3u}$  □

Second, notice that in case that  $d$  was used as unfolding clause for going from  $P_2$  to  $P_{2u}$ , then some instances of  $\tilde{B}\theta$  were propagated into  $P_{3u}$ . Using the notation of the diagram, this is the case when some  $\tilde{N}_i$  (in  $P_2$ ) is of the form  $A', \tilde{F}_i$  where  $A$  and  $A'$  are unifiable atoms, then one of the  $\tilde{D}_{i,j}$  (in  $P_{2u}$ ) is of the form  $\tilde{D}_{i,j} = (\tilde{B}, \tilde{F}_i)\theta'$ . However, if we unfold  $\tilde{N}_i$  in  $P_4$ , what we get is  $\tilde{D}'_{i,j} = H\theta', \tilde{F}_i$ , that has  $H\theta'$  instead of  $\tilde{B}\theta'$ . By the same argument used for  $\theta\gamma_{i,j}$  in 4.3, we have that

*Observation 25*

- $H\theta' \sim_{P_{3u}} \exists(\tilde{w}\theta') \tilde{B}\theta'$
- $H\theta'$  is not-slower than  $\exists(\tilde{w}\theta') \tilde{B}\theta'$  in  $P_{3u}$  □

So in order to obtain  $P_{4u}$  from  $P_{3u}$  we have then to do two things: First, replace  $\tilde{B}\theta$ , with the corresponding  $H\theta$  in all the clauses  $d$  that are transformed in *Step 4*. Second, replace  $\tilde{B}\theta'$  with  $H\theta'$  in the  $\tilde{D}_{i,j}$  so that  $P_{4u}$  contains  $\tilde{D}'_{i,j}$  instead of  $\tilde{D}_{i,j}$ . This tantamounts to the application of a simultaneous replacement. From *Observations 24* and *25*, and *Theorem 16* we have that

$$Fit(P_{3u}) = Fit(P_{4u}) \quad (5)$$

Moreover  $P_{4u}$  is obtainable from  $P_4$  by unfolding all the atoms in the conjunctions  $\tilde{N}_i$  in the clauses where they occur. Hence

$$Fit(P_4) = Fit(P_{4u}). \quad (6)$$

So far, because of (1), (2), (3), (4) and (5), we have the following

**Proposition 26.** *If condition A holds and  $\tilde{B}$  does not contain negative literals, then*

$$- Fit(P_1) = Fit(P_2) = Fit(P_3) = Fit(P_4) \quad \square$$

#### 4.4 The general case

We can finally prove Theorem 6. Let us state it again.

**Theorem 6.** *Let  $P_1, \dots, P_4$  be a sequence of programs obtained applying the transformation schema to program  $P$ , Let also  $D_{\text{def}} = \{H_i \leftarrow \tilde{B}_i\}$  be the set of clauses introduced in Step 1, and, for each  $i$ ,  $\tilde{w}_i$  be the set of local variables of  $c_i$ :  $\tilde{w}_i = \text{Var}(\tilde{B}_i) \setminus \text{Var}(H_i)$ . If each  $c_i$  in  $D_{\text{def}}$  satisfies the following condition:*

**A** *each time that  $\exists \tilde{w}_i \tilde{B}_i \theta$  is false in some  $\Phi_{P_1}^{\uparrow\beta}$ , then there exists a non-limit ordinal  $\alpha \leq \beta$  such that  $\exists \tilde{w}_i \tilde{B}_i \theta$  is false in  $\Phi_{P_1}^{\uparrow\alpha}$*

*Then  $\text{Fit}(P_1) = \text{Fit}(P_2) = \text{Fit}(P_3) = \text{Fit}(P_4)$ .*

**Proof.** We consider here the simplified case in which *Step 1* introduces only one clause which in turn contains only one negative literal in the body, i.e.  $D_{\text{def}} = \{c_0 : H \leftarrow \neg l(\tilde{y}), \tilde{B}'\}$ . The generalization to the case of multiple clauses and multiple negative literals is straightforward and omitted here. Notice that if  $c_0$  contained no negative literals, then the result would follow directly from Proposition 26.

We now perform a double transformation on  $P_1$ : first, we enlarge it with the following new definition:  $d : \text{not}l(\tilde{y}) \leftarrow \neg l(\tilde{y})$ ; then, we replace each instance  $\neg l(\tilde{t})$  of  $l(\tilde{y})$  that occurs in the body of a clause with the corresponding instance  $\text{not}l(\tilde{t})$  of  $\text{not}l(\tilde{y})$ . This replacement operation clearly preserves Fitting's model of the programs, in fact it can be undone by unfolding. Let us call  $P'_1$  the program so obtained. We have that

$$\text{Fit}(P_1) = \text{Fit}(P'_1)|_{B_{P_1}} \quad (7)$$

Where  $\text{Fit}(P'_1)|_{B_{P_1}}$  denotes the restriction of  $\text{Fit}(P'_1)$  to the atoms in the Herbrand base of  $P_1$ .

Now  $P'_1$  contains, instead of clause  $c_0$ , the following:  $c'_0 = H \leftarrow \text{not}l(\tilde{y}), \tilde{B}'$ . which is a *definite* clause.

Now notice that, since the unfold operation is defined only for positive literals, then  $\neg l(\tilde{y})$  is never unfolded in the transformation  $P_1 \dots P_4$ . It follows that, by performing the same operations used for going from  $P_1$  to  $P_4$ , we can obtain another "parallel sequence"  $P'_1 \dots P'_4$  that starts with program  $P'_1$ . By the same arguments used to prove (7), we have that, for  $i \in [1 \dots 4]$ ,

$$\text{Fit}(P_i) = \text{Fit}(P'_i)|_{B_{P_i}} \quad (8)$$

Moreover, by Proposition 26,

$$\text{Fit}(P'_1) = \text{Fit}(P'_2) = \text{Fit}(P'_3) = \text{Fit}(P'_4) \quad (9)$$

From (8) and (9) the thesis follows.  $\square$
