Just Accepted

“Just Accepted” manuscripts have been peer-reviewed and accepted for publication. They are posted online prior to technical editing, formatting for publication and author proofing. The American Chemical Society provides “Just Accepted” as a service to the research community to expedite the dissemination of scientific material as soon as possible after acceptance. “Just Accepted” manuscripts appear in full in PDF format accompanied by an HTML abstract. “Just Accepted” manuscripts have been fully peer reviewed, but should not be considered the official version of record. They are citable by the Digital Object Identifier (DOI®). “Just Accepted” is an optional service offered to authors. Therefore, the “Just Accepted” Web site may not include all articles that will be published in the journal. After a manuscript is technically edited and formatted, it will be removed from the “Just Accepted” Web site and published as an ASAP article. Note that technical editing may introduce minor changes to the manuscript text and/or graphics which could affect content, and all legal disclaimers and ethical guidelines that apply to the journal pertain. ACS cannot be held responsible for errors or consequences arising from the use of information contained in these “Just Accepted” manuscripts.

molecular separation, liquid-vapor interfacial polymerization, thioether-based network.

ABSTRACT: As nanofiltration applications increase in diversity, there is a need for new
fabrication methods to prepare chemically and thermally stable membranes with high retention
performance. In this work, thio-bromo “click” chemistry was adapted for the fabrication of a
robust covalently attached and ultrathin nanofiltration membrane. The selective layer was formed
on a pre-functionalized porous ceramic surface via a novel, liquid-vapor interfacial
polymerization method. Compared to the most common conventional interfacial polymerization

1
2
3 procedure, no harmful solvents and a minimal amount of reagents were used. The properties of
4 the membrane selective-layer and its free-standing equivalent were characterized by
5
6 complementary physico-chemical analysis. The stability of the thin selective layer was
7
8 established in water, ethanol, non-polar solvents and up to 150°C. The potential as a
9
10 nanofiltration membrane was confirmed through solvent permeability tests (water, ethanol,
11
12 hexane, toluene), PEG-in-water molecular weight cut-off measurements ($\approx 700 \text{ g mol}^{-1}$) and dye
13
14 retention measurements.

20 21 **Introduction**

22
23
24 Separation, recovery and disposal of liquid mixtures in industry accounts for at least 40 – 70%
25
26 of both capital and operating costs.^{1,2} Membrane-based technologies have shown potential as
27
28 alternative or complement of conventional separation and purification processes thanks to their
29
30 easy operation, high separation efficiency, low energy consumption, and eco-friendliness.³ This
31
32 has been observed particularly for the purification of water or organic solvents under extreme
33
34 process conditions (e.g. high pressure and/or temperature),¹ where nanofiltration (NF)
35
36 membranes are ideal for the removal of small organic solutes with a molecular size between 0.5
37
38 and 2 nm (like antibiotics, catalysts etc.).
39
40
41

42
43 Interfacial polymerization (IP) is extensively used for the preparation of NF membranes. This
44
45 method allows the formation of ultrathin dense polymeric networks on porous substrates by a
46
47 controlled polymerization process at the interface of two immiscible phases (e.g. water-
48
49 toluene).^{4,5} Unfortunately, the fabrication of NF membranes with good separation performance
50
51 by IP implies the use of solvents and monomers in a large excess⁶ (e.g. at least 1 – 3 wt.%) due
52
53
54
55
56
57
58
59
60

1
2
3 to the low monomer to polymer conversions⁷ and byproduct formation. As a result, large
4 quantities of waste are produced, which is one of the major drawbacks of the IP method.⁸
5
6

7
8 Also, despite the excellent performance reported for the NF membranes prepared by the IP
9 method, the resulting polymeric layers present a low mechanical and chemical stability under
10 severe conditions (i.e., extreme pH values, bleach, and other reactive chemicals).^{9,10} This
11 correlates to the monomers used which are usually composed of halogenated acids, such as
12 trimesoyl chloride (TMC), and diamine benzene-derivatives (DAB). A combination of these
13 types of monomers facilitates the formation of crosslinked polymeric networks at short reaction
14 times, which leads to enhanced chemical stability in polar and apolar solvents. However, the
15 amide bonds formed during the reaction between these two types of monomers (TMC and
16 DABs) are very sensitive to hydrolysis and cannot thus withstand strong acids, bases, or
17 hypochlorite-based cleaning treatments.^{11,12} Additionally, swelling and detachment of the
18 membrane from the porous substrates can occur during the cleaning treatment as the
19 conventional IP process does not involve a covalent attachment between membrane and the
20 substrate surface. Therefore, there is a need to adjust the IP reaction process to mitigate waste
21 production and to increase the chemical and mechanical stability of the NF membranes
22 produced.

40
41

42 To overcome the challenges of conventional IP methods, “click” chemistry can be used
43 instead of amidization reactions. “Click” chemistry is a tool used for the fabrication of highly
44 cross-linked and chemically stable polymers. This method is characterized by a high reaction
45 yield and low waste production.¹³ Besides, “click” reactions can promote the formation of
46 chemical linkages that are chemically inert even under extreme conditions. Among the existing
47 possibilities, the thio-bromo “click” reaction, which occurs at room temperature under basic
48

58
59
60

1
2
3 conditions (pH < 9), results in stable thioether bonds which can be used as an alternative to
4
5 conventional amidization reactions used in conventional IP methods.
6

7
8 In 2005, Timmerman *et al.*¹⁴ established the first thio-bromo “click” reaction synthesis to
9
10 prepare cyclic peptides in high yields and more rapidly than conventional synthesis methods. The
11
12 resulting products were made via the reaction of cysteine-based peptides as thiol substituted with
13
14 benzylic bromides under mild basic conditions (pH ~8).¹⁵ The method was expanded to the
15
16 preparation of polymers by Monnereau *et al.* in 2015.¹⁶ Hyper-crosslinked thioether-based
17
18 porous polymers were formed under similar conditions. These networks were shown to be
19
20 insoluble in common organic solvents and were thermally stable up to 500 °C. “Click” reactions
21
22 show great potential for use in membrane technology due to the simplicity, the high yields of the
23
24 reaction conditions, and the resulting chemical stability of the polymers formed. Most studies
25
26 using “click” chemistry focused on minor precursor modifications either before^{18–20} or after^{21,22}
27
28 the layer formation. However, thus far no study has used the powerful and high yielding “click”
29
30 reactions to form distinct membrane selective layers. Therefore, by adapting the IP method with
31
32 the “click” reactions, ultrathin and selective membrane layers can be formed. A proof of concept
33
34 was shown by Rapakousiou *et al.* in 2017,¹⁷ where the liquid/liquid IP method in combination
35
36 with the “click” reaction of copper-catalysed azide-alkyne cycloaddition (CuAAC) was used to
37
38 form an ultrathin polymer with thickness of 5 nm. In this work, we propose a novel method
39
40 towards the formation of an ultrathin cross-linked NF membrane composed of stable thioether
41
42 bonds. Starting from the top surface of a pre-functionalized porous ceramic support, two
43
44 successive thio-bromo “click” reactions are conducted to form the NF separation layer. Here, the
45
46 “click” reaction is also used to covalently attach the polymeric layer on top of a porous ceramic
47
48 support. Ceramic supports, which exhibit high thermal and chemical stability, do not suffer from
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3 plasticization issues, swelling, or thermal degradation; phenomena observed with common
4
5 porous polymeric supports. In addition, ceramic supports can be easily functionalized with a
6
7 wide range of small organic molecules²¹ including thiol-terminated ones.²² Even though IP layers
8
9 have been successfully formed on ceramic supports in the past,²³ only conventional IP
10
11 (polyamides predominantly) procedures were used and to-date no covalent attachment between
12
13 selective layer and the ceramic support has been reported. In this work the second “click”
14
15 reaction is done via a vapor phase reaction without the use of a catalyst. For the first time we
16
17 report a selective layer made completely *via* “click” chemistry. A special effort is devoted to
18
19 understanding the impact of each reaction step on the final layer as well as the thermal and
20
21 chemical stability of the network. The system reported here can serve as a proof-of-concept for
22
23 developing thioether-based layers for a wide range of applications such as in membrane science,
24
25 coatings, optoelectronics and many more.

Information. The α -alumina (α -Al₂O₃) substrates (disc: 21 or 39 mm of diameter, 2 mm of thickness, 80 nm pore diameter) were purchased from Pervatech B.V., the Netherlands. These ceramic substrates are comprised primarily of macroporous α -alumina (> 99 %), which ensures mechanical stability under pressure. The polished side of these supports was dip-coated with a boehmite sol and subsequently calcined at 650 °C for 3 hours. The procedure was performed twice to eliminate any defects on the surface of the γ -alumina support and led to the formation of a thin γ -alumina layer of 3 μ m in total thickness (Figure S2.B of the Supporting Information). Further details for the fabrication of the γ -alumina coated support can be found elsewhere.²⁴⁻²⁶

Thioether-based cross-linked NF membrane preparation

Prior to use the mesoporous γ -alumina supports, these were soaked in a water/ethanol mixture (v/v = 2:1) for 8 h before drying under vacuum at 50 °C. The synthesis of the thioether-based cross-linked membrane is divided in three steps as described in Scheme 1.

A. Grafting of MPTMS *via* vapor phase deposition

B. Thioether-based layer *via* thio-bromo click reaction

1

7
8
9

10
11 **Porous support pre-functionalization:** The grafting of (3-mercaptopropyl)trimethoxysilane
12 (MPTMS) was conducted using the vapor phase grafting method. Prior the synthesis, γ -alumina
13 support was filled with glycerol by rubbing a drop (≈ 1 mL) onto the substrate surface and after
14 10 min stand time, dabbed with a tissue. Vapor phase grafting was conducted by placing a
15 glycerol-filled γ -alumina support (top-surface facing down) 2 – 3 cm above 50 mL of a 25 mM
16 anisole solution of MPTMS at 105°C for 3h (Figure S4). After cooling to room temperature, the
17 pre-functionalized porous support was washed with 20 mL anisole for 1h under sonication to
18 remove the physisorbed species, and dried overnight at 50°C under vacuum. Samples obtained at
19 this stage were denoted Al-SiM.

8
9
10

11 **Characterization**

12
13
14
15 Fourier Transform Infrared spectroscopy (FTIR) measurements were done using a Perkin
16
17 Elmer UATR Spectrum Two. Wavenumbers between 4000 and 550 cm^{-1} were scanned in
18
19 reflectance mode at a resolution of 4 cm^{-1} for a minimum of 16 scans.
20
21
22

23 Field-emission scanning electron microscopy (FE-SEM) images were obtained with a Zeiss
24
25 MERLIN high-resolution scanning electron microscope using an accelerating voltage of 1.4 kV.
26
27 FE-SEM samples were sputtered with 2 nm of chromium to avoid sample charging.
28
29
30

31 Thermogravimetric analysis (TGA) coupled with differential scanning calorimetry (DSC) and
32
33 mass spectroscopy (MS) was conducted using an STA 449 F3 Jupiter (Netzsch), equipped with a
34
35 dual TG/DSC sample/reference holder. Measurements were performed under 55 mL min^{-1} N_2
36
37 and 15 mL min^{-1} O_2 flow with a heating rate of 10 $^\circ\text{C min}^{-1}$ from 40 to 800 $^\circ\text{C}$. Calibrations were
38
39 made using melting standards. Measurements were run sample-temperature controlled. The
40
41 sample masses were determined using an internal balance 30 min after inserting the sample. The
42
43 gases evolved during TGA analysis were transferred to a mass spectrometer (QMS 403 D
44
45 Aëolos, Netzsch). TGA and MS start times were synchronized, but no correction was applied for
46
47 the time offset caused by the transfer line time (estimated < 30 s, systematic offset). A bar graph
48
49 scan for $m/z = 1-110$ amu was recorded for all samples to determine the evolving m/z numbers.
50
51
52
53
54 TGA/DSC crucible correction can be found in Supporting Information, Figure S12.
55
56
57
58
59
60

1
2
3 Pore size of the mesoporous alumina membranes was determined by permoporometry using
4 cyclohexane as condensable vapor. The experimental procedure is described in detail
5
6
7 elsewhere.²⁷
8
9

10
11 X-ray fluorescence spectroscopy (XRF) measurements were conducted on a Bruker SS Tiger
12 using membrane samples prepared via the stepwise membrane method described above.
13
14 Complete elemental analysis is provided in the Supporting Information.
15
16
17

18
19 Spectroscopic ellipsometry was performed using a J.A. Woollam M-2000 ellipsometer on
20 silicon wafer (one side polished, CZ test grade, Silchem) samples coated in a fashion identical to
21 the prepared Al-SiM, Al-SiM/Br and Al-SiM/TE membrane samples without the glycerol pre-
22 treatment step. First, a piece of silicon wafer (30x30 mm) with a native oxide layer was cleaned
23 in an oxygen plasma chamber for 10 min at 100 watts. Any residual organics were washed off
24 with ethanol and then, the wafer was dried under vacuum at 50 °C overnight. The preparation of
25 the coatings followed the stepwise protocol developed for the preparation of the thioether-based
26 membrane except that no pore-filling agent was used. After each reaction step, a part of the
27 substrate was preserved for the analysis (Figure S13). Each sample was rinsed with ethanol
28 multiple times and dried under vacuum overnight at 50 °C and stored under N₂ at room
29 temperature. The detailed parameters to assess the layer thickness can be found in the Supporting
30 Information.

48 **Membrane screening and performance tests**

49

50
51 Permeability and retention data were collected with a custom-made, dead-end filtration setup,
52 consisting of a nitrogen tank pressurizing a feed vessel with a valve to regulate pressure.
53
54
55
56
57
58
59
60

1
2
3 Permeability is expressed as the flux of water or a solvent across a membrane per unit of driving
4 force, here as liters per square meter of exposed membrane area (2.4 or 9.1 cm²) per hour per bar
5
6 of pressure applied across the membrane (L m⁻² h⁻¹ bar⁻¹). Permeability data were collected by
7
8 weighing the flow of permeate at timed intervals and at three applied transmembrane pressures
9
10 between 8 and 15 bar, and by taking the slope of a linear fit of the collected data. All slopes were
11
12 found to be linear unless otherwise noted. A permeability of 0.0 indicates no detected solvent
13
14 flux during 17 h of operation at a transmembrane pressure of 15 bar.
15
16
17
18
19

20 Retentions (*R*) of Brilliant Yellow (BY, *M*_w = 624.55 g mol⁻¹, 50 ppm), Rhodamine B (RB,
21
22 *M*_w = 479.02 g mol⁻¹, 50 ppm), Sudan Black B (SBB, *M*_w = 457 g mol⁻¹, 50 ppm) or PEG
23
24 oligomers (*M*_w = 300, 600, 1000, 1500 g mol⁻¹) were calculated by the equation
25
26

$$R = 1 - c_p/c_f \quad (1)$$

27
28
29
30 where *c*_p and *c*_f are the permeate and feed solute concentrations, respectively. Retention
31
32 samples were obtained at recoveries between 15-25%. Solute concentrations of BY, RB and SBB
33
34 were calculated from Perkin-Elmer λ12 UV-Vis spectrophotometer results at the characteristic
35
36 wavelength of 401.5 (BY), 554 (RB) and 604 (SBB) nm. PEG concentrations were determined
37
38 by gel permeation chromatography (GPC). The GPC setup consisted of two SUPREMA 100 Å
39
40 columns from PSS Polymer Standards Service GmbH (Germany), an HPLC pump from Waters
41
42 (Millipore B.V., The Netherlands) and a Shodex RI-Detector from Showa Denko GmbH
43
44 (Germany). The columns were calibrated using the same PEG standards.
45
46
47
48
49

50 **Results and Discussion**

51 52 53 **Porous support pre-functionalization with MPTMS**

54
55
56
57
58
59
60

1
2
3 The porous γ -alumina top-surface was pre-functionalized with 3-
4 (mercaptopropyl)trimethoxysilane (MPTMS), a precursor for the thioether-based network, using
5 a vapor phase deposition grafting method (Scheme 1A). Here, the alkoxy silane linking groups of
6 the precursor react with the hydroxyl-rich surface of the γ -alumina support via a condensation
7 reaction, yielding a homogeneous monolayer coverage without poly(homo)condensation
8 reactions.²¹

9
10 FTIR analysis was used to demonstrate the grafting of the MPTMS precursor on the top-
11 surface of the porous γ -alumina support. The FTIR spectrum of the pristine (Al) and pre-
12 functionalized γ -support (Al-SiM) in the range 3800 – 2300 cm^{-1} and 1800 – 960 cm^{-1} are
13 presented in Figure 1A and 1B. The bands appearing on the Al-SiM spectrum between 2840 and
14 2950 cm^{-1} correspond to the symmetric and antisymmetric C–H stretching vibrations of the
15 precursor's aliphatic group. The grafting is suggested by the disappearance of a sharp vibration
16 band at 2840 cm^{-1} which corresponds to the Si-OCH₃ group of the MPTMS precursor (Figure
17 S11, Supporting Information, section 5). This is also confirmed by the presence of a broad
18 vibration band centered at 1050 cm^{-1} on the Al-SiM spectrum, which can be ascribed to the
19 newly formed Si-O-Al bond and is not visible in the spectrum of the pristine support (Al).²⁸
20 Compared to the FTIR spectrum of the precursor, the weak stretching vibration band of the thiol
21 group (S-H) located at 2565 cm^{-1} is not visible for the Al-SiM sample. This can be due to the low
22 concentration of grafted molecules on the pre-functionalized surface and the weak absorbance of
23 the S-H group in this IR region.²⁹

Figure 1. FTIR spectra of the Al, Al-SiM, Al-SiM/Br and Al-SiM/TE samples between 3800 – 2300 cm^{-1} (A) and 1800 – 960 cm^{-1} (B). The symbol (*) denotes the vibration band attributed to physisorbed water.²³

XRF was used to further confirm the presence and conservation of the side chain of the MPTMS precursor after grafting. The results are presented in Table S1 (Supporting Information, section 6). The analysis revealed the presence of silicon and sulfur, respectively 0.3% and 0.3%;

1
2
3 thus, confirming along with the FTIR results that the support has been successfully
4
5 functionalized.
6
7

8
9 Cyclohexane permoporometry was used to investigate the possible blocking of the support pores
10 due to poly(homo)condensation reactions of the MPTMS precursor. Indeed, the presence of
11 precursors into the pores can affect the formation and properties of the resulting NF thioether-
12 based membrane. The oxygen flux through the Al-SiM and the unmodified γ -alumina support as
13 a function of the relative cyclohexane pressure during the desorption step of the permoporometry
14 analysis is shown in Figure S13A (Supporting Information, section 7). At the beginning of the
15 desorption step, all the pores are blocked with condensed cyclohexane and there is no oxygen
16 flux. In the interval $0.5 > P/P_0 > 0.3$, the oxygen permeance increases with the increase in
17 number of open pores. By considering that the capillary condensation process takes place in this
18 interval, Kelvin diameters of ~ 5.5 and ~ 5 nm (Supporting Info, section 7) were calculated for
19 the unmodified γ -alumina support and the Al-SiM sample (5.5 ± 0.03 and 4.8 ± 0.07 ,
20 accordingly). The results are very similar, and we can thus conclude in the successful grafting of
21 MPTMS on support's top-surface without poly(homo)condensation reactions into the pores.

40 **Formation of the thioether-based hyper cross-linked membrane**

41
42
43 Prior to the membrane fabrication, thioether-based free-standing films were prepared as a
44 proof-of-concept via the liquid-liquid IP (LIP) method. The LIP method, in contrast to a single
45 solvent system, allows for formation of a well-defined organic network.³⁰ Preparation of LIP
46 free-standing films was proven to be crucial in determining potential side reactions by ^1H liquid
47 NMR and the physico-chemical properties of the membrane layer such as thermal and chemical

3 stability. The preparation procedure and the physico-chemical characterizations of the film is
4 reported in the Supporting Information (section 4).
5
6

7
8
9 Thioether-based cross-linked membranes were prepared on the pre-functionalized support (Al-
10 SiM) in two steps, as shown in Scheme 1B. The first step consisted in the deposition of a basic
11 solution of the 1,3,5-tris(bromomethyl)benzene (3Br) monomer onto the pre-functionalized
12 porous ceramic support. Under these solution phase conditions, the thiol surface groups of the
13 grafted precursors can react with the 3Br monomer via the thio-bromo “click” reaction, forming
14 a thioether bond (Al-SiM/Br). The base catalyst (TEOA, $pK_a \approx 11$)³¹ was added to the 3Br
15 monomer solution to minimize the formation of disulfide bonds, which were detected by ¹H
16 liquid NMR during the preparation of the film (Figure S9 and S10, Supporting Information,
17 section 4). Disulfide bonds are in general weaker than thioether bonds since they can be cleaved
18 under mild conditions^{32,33} and thus their presence in the final membrane layer is viewed as
19 defects. Subsequently, the support surface was exposed to 1,3-benzenedithiol (2SH) monomer
20 vapors, leading to the formation of a thioether-based cross-linked membrane (Al-SiM/TE,
21 Scheme 1B, step 2). This second step, was done without the use of base catalyst since the
22 nucleophile in the vapor phase has enough energy to overcome the kinetic barrier of the “click”
23 reaction.^{34,35} Therefore, the 2SH monomer in the vapor phase is expected to react with the 3Br
24 monomer in contact with the liquid phase. Thus, we expect that the “click” polymerization
25 reaction occurs at the liquid-vapor interface and thus an interfacial polymerization should take
26 place on top of the ceramic support. The reaction parameters for the preparation of Al-SiM/TE
27 sample (Scheme 1B) were selected by screening through different reaction conditions (reaction
28 times, and monomer concentrations). A combination of Sudan Black B ($M_w = 457 \text{ g mol}^{-1}$)
29 retention tests and solvent permeability measurements were conducted to identify the samples

2
3 showing the presence of a distinct selective and permeable layer on top of the support. The
4
5 results of this preliminary study are summarized in the Supporting Information (section 8).
6
7

8
9 To confirm the formation of the thioether-based cross-linked network, FTIR analysis was
10
11 conducted after each reaction step, on the respective samples Al-SiM/Br and Al-SiM/TE. The
12
13 FTIR spectra in the range 3800 – 2300 cm^{-1} and 1800 – 960 cm^{-1} are presented in Figure 1A and
14
15 B respectively. For these samples, the presence of aromatic rings is confirmed by the quadrant
16
17 stretching vibration band observed at 1602 cm^{-1} ($\nu(\text{C}=\text{C})$). Moreover, this assumption is also
18
19 verified by the multiple bands appearing at 1484, 1450, 1440 and 1412 cm^{-1} which are associated
20
21 with the stretching and bending vibrations of the aromatic rings ($\nu(\text{C}=\text{C})$ and $\delta(\text{=CH})$).^{29,36} The
22
23 good signal resolution of these vibration bands in the case of the Al-SiM/TE sample suggests the
24
25 increase in concentration of aromatic rings, as compared to the Al-SiM/Br sample, which is
26
27 attributed to the vapor phase “click” reaction (Scheme 1B, step 2). The absorption band at 1249
28
29 cm^{-1} , appearing in both samples, is attributed to the wagging vibration of the methyl group at the
30
31 benzylic position, $\text{Ph-CH}_2\text{-X}$, where X is either a sulfur or a bromine atom.³⁷ To determine if this
32
33 vibration band resulted from the formation of thioether bonds or unreacted 3Br monomers, the
34
35 spectra were compared to the spectrum of the pure 3Br monomer (Figure S14, Supporting
36
37 Information, section). Even though, in the spectrum of the 3Br monomer, the vibration of the
38
39 methyl group ($\text{Ph-CH}_2\text{-Br}$) appears at 1209 cm^{-1} , the presence of the bromine in the Al-SiM/Br
40
41 or /TE cannot be excluded and further in-depth analysis is required. Moreover, disappearance of
42
43 the C-Br absorption band at 704 cm^{-1} would indicate full conversion of the benzylic bromides to
44
45 thioethers in the membrane layer. However, no specific signals can be observed below 900 cm^{-1}
46
47 in the case of the Al-SiM/TE membrane due to the high intensity of the signal attributed to the
48
49 alumina support (Figure S14, Supporting Information, section 9). Here, the free-standing film
50
51
52
53
54
55
56

1
2
3 can be used since it is spectroscopically identical to the Al-SiM/TE. According to the FTIR of
4
5 the film, an absorption band at 710 cm^{-1} is present which can be attributed to both unreacted
6
7 methyl bromides (C-Br)²⁹ or the desirable thioether bonds (C-S-C).^{38,39} Thus, from the FTIR
8
9 results thioether-bond formation is indicated, however the presence of bromide in the sample
10
11 cannot be excluded and further investigation is necessary.
12
13
14

15
16 XRF analysis was conducted to determine the amount of sulfur and the presence of any
17
18 residual bromine in the final thioether-based membrane. The results are given in Table S1
19
20 (Supporting Information, section 6). The weight concentration of sulfur is increasing by 1.3%
21
22 between the Al-SiM and Al-SiM/TE samples which confirms the increase concentration of
23
24 thioether bonds on the surface (Al-SiM: 0.3 wt%; Al-SiM/TE: 2.0 wt%). Less than 0.1 wt% of
25
26 bromine was detected in the Al-SiM/TE sample which suggests the predominance of the
27
28 thioether-based bond formation.
29
30
31

32
33 To study the pore size of the membrane and to confirm the formation of a defect-free layer as
34
35 suggested by the preliminary SBB retention tests, cyclohexane permoporometry experiments were
36
37 conducted. The oxygen flux through the Al-SiM/Br and Al-SiM/TE samples as a function of the
38
39 relative cyclohexane pressure during the desorption step is shown in Figure S13A and B of the
40
41 Supporting Information (section 7). A pore diameter of $\sim 4\text{ nm}$ is determined for the Al-SiM/Br
42
43 sample which indicates a pore shrinkage of $\sim 1\text{ nm}$ compared to the unmodified γ -alumina
44
45 support. This decrease in pore diameter can be attributed to the presence of the 3Br monomers
46
47 which have reacted in step 1 with the thiol surface groups, present at the pores entrance (Scheme
48
49 1B). Concerning the Al-SiM/TE sample, an oxygen permeance of $1 \times 10^{-8}\text{ mol s}^{-1}\text{ m}^{-2}\text{ Pa}^{-1}$ was
50
51
52
53
54
55
56
57
58
59
60

1
2
3
4 obtained (Figure S13A). This value corresponds to the detection limit of the setup. The absence
5
6
7 of a clear transition point in the cyclohexane permoporometry curve suggests firstly the complete
8
9 coverage of the γ -alumina porous support with the thioether-based network, and secondly that
10
11 the Al-SiM/TE sample is mainly composed of micropores (pore diameter < 2 nm).
12
13

14
15 According to literature,⁴⁰⁻⁴² the pore size of the layer can also be estimated using retention
16
17 tests of a series of PEG molecules with different molecular weights (M_w). It is known that PEG
18
19 molecules can form spheres in solution of certain radius, which can be estimated via the Stokes-
20
21 Einstein equation (2):
22
23

$$24 \quad \text{Molecular radius (\AA)} = 0.1673 \times (M_w \text{ (g/mol)})^{0.557} \quad (2)$$

25
26
27
28 where M_w is the molecular weight of the PEG which is 90% retained by the membrane.
29
30

31
32 Figure S15 in the Supporting Information (section 10) shows the PEG retention obtained for the
33
34 Al-SiM/TE sample. A molecular weight cut-off (MWCO) of $\approx 700 \text{ g mol}^{-1}$ was obtained which is
35
36 much lower the MWCO of unmodified γ -alumina support (2500 g mol^{-1}),⁴³ and well in the
37
38 nanofiltration range.¹ Using the MWCO and the equation (2), a hydrodynamic diameter of 1.3
39
40 nm was calculated. This value is in accordance with the pore diameter suggested by the
41
42 cyclohexane permoporometry measurements (pore diameter below 2 nm) and in the pore range
43
44 needed for NF applications.
45
46
47

48
49 FE-SEM analysis was used to investigate the morphology, location, and homogeneity of the
50
51 Al-SiM/TE membrane. Figure 2A shows a cross-section image of the membrane with part of the
52
53 α -alumina support and the γ -alumina layer consistent with reported characteristics.^{24,25} No
54
55
56

58
59
60

1
2
3 organic layer was observed on the top surface until higher magnification was used, as shown in
4
5 Figure 2B, where a thin organic layer is indicated. The organic layer seems to be in direct contact
6
7 with the γ -alumina support. However, as shown in Figure 2B, the top layer also appears in a
8
9 different location in the form of thin flakes detached from the supports. The detachment can be
10
11 artefacts induced either by the primary electron beam or the high vacuum of the SEM equipment.
12
13
14 Based on these observations, the layer thickness should not be more than 50 nm.

40
41
42
43

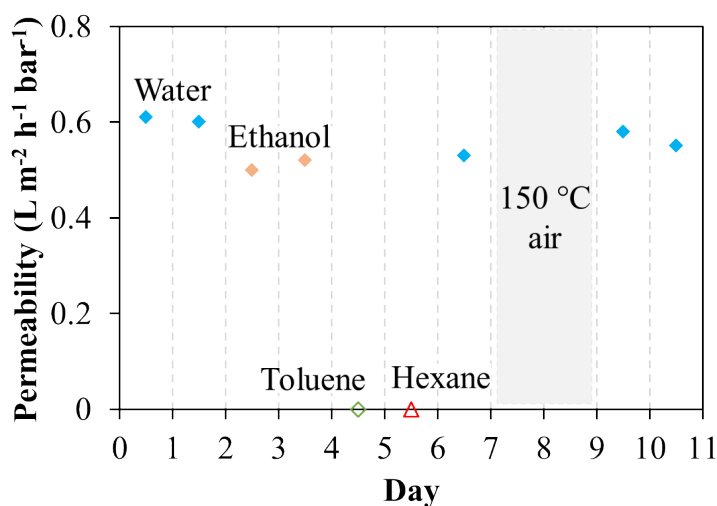

44 For insight into the thickness of the thioether-based layer, spectroscopic ellipsometry
45 measurements were performed. Ellipsometry has been used to measure the thickness of
46
47 polymeric film prepared by conventional LIP.⁴⁴ However, due to the roughness and porosity of
48
49 the γ -alumina support it is impossible to apply this analysis to the Al-SiM/TE membrane. Thus,
50
51 the membrane synthesis was transposed onto silicon wafer substrates to study layer formation
52
53
54
55
56
57
58
59
60

1
2
3 after each reaction step. Grafting of MPTMS on the silicon wafer yields a thin layer of 1.0 ± 0.1
4 nm. This thickness value is in accordance with MPTMS layers prepared by Gothe et al.⁴⁵ After
5
6 the first “click” reaction with the 3Br monomer, an increase in thickness of ~ 0.3 nm was
7
8 measured. Finally, after the second “click” reaction with the 2SH monomer by VIP an ultrathin
9
10 thioether-based layer is formed with a thickness of 7.8 ± 0.4 nm. We expect that when prepared
11
12 on the porous membrane support, the thickness of the thioether-based layer would be higher than
13
14 the one shown by ellipsometry due to the inherent porosity of the γ -alumina support. Even
15
16 though, the pores of the support are filled with glycerol, monomers are expected to be able to
17
18 infiltrate the porous ceramic during the VIP step and to form a thicker layer than the one
19
20 observed with ellipsometry. Nevertheless, the thickness of the membrane separation layer is
21
22 expected to be very thin and thus would not be observed by FE-SEM.
23
24
25
26
27
28
29

30 **Stability of the thioether-based cross-linked membrane**

31
32
33
34 The stability of the thioether-based network was assessed first through exposure to different
35
36 solvents. Permeability tests were conducted with solvents of different polarity (water, ethanol,
37
38 toluene and hexane) under the same conditions. A thermal treatment was included in the test to
39
40 study any potential degradation of the structure caused by the temperature or the solvent tested.
41
42 As shown in Figure 3, the water permeability of the Al-SiM/TE membrane is approximately 0.60
43
44 ± 0.05 L m⁻² h⁻¹ bar⁻¹ and similar to ethanol permeability (0.50 ± 0.02 L m⁻² h⁻¹ bar⁻¹). Compared
45
46 to the water permeability of the γ -alumina coated support (6 L m⁻² h⁻¹ bar⁻¹) and the bare α -
47
48 alumina ($7 - 8$ L m⁻² h⁻¹ bar⁻¹) support,⁴⁰ the thioether based membrane exhibits approximately
49
50 one order of magnitude lower permeability, which suggests the presence of a layer on top of the
51
52 support. The Al-SiM/TE membrane was found impermeable to apolar solvents, such as toluene
53
54
55
56

1
2
3 and hexane. This suggests that either the organic layer has collapsed and a dense network has
4 formed in contact with the apolar medium or the organic layer has a rigid hydrophilic structure,
5 impermeable to apolar solvents. To ascertain which is the case, the membrane was dried and re-
6 tested with water. As shown in Figure 3 the water permeability showed a slight change ($0.53 \text{ L m}^{-2} \text{ h}^{-1} \text{ bar}^{-1}$),
7 which is attributed to incomplete drying of the apolar solvents between the tests.
8 However, the results suggest that thioether-based layer did not collapse in presence of apolar
9 solvent. Thus, formation of a rigid hydrophilic network via the VIP method is indicated.

20

23
24
25
26
27
28
29
30
31
32
33
34
35
36
37 **Figure 3.** The permeability of various solvents through the same membrane over consecutive
38 tests. The same membrane was exposed to heat for 2 days and then the water permeability was
39 tested for 2 consecutive days. Between each permeability test the sample was dried overnight at
40 $50 \text{ }^\circ\text{C}$ under vacuum.
41
42
43
44
45

46
47 Following the solvent permeability tests, the thermal stability of Al-SiM/TE membrane was
48 further investigated. The sample was thermally treated at $150 \text{ }^\circ\text{C}$ during 48h and a water
49 permeability of $0.57 \text{ L m}^{-2} \text{ h}^{-1} \text{ bar}^{-1}$ was measured. This value is within error from the value
50 obtained before the thermal treatment ($0.53 \text{ L m}^{-2} \text{ h}^{-1} \text{ bar}^{-1}$).
51
52
53
54
55

To further confirm the integrity of the network, a free-standing film was analyzed by TGA-MS and FTIR spectroscopy. The TGA results indicate that the thioether-based layer is thermally stable below 300 °C, where no weight loss was observed (Figure S17, Supporting Information, section 13). Above 310 °C, thermal degradation occurs with a significant weight loss above 460 °C. FTIR analysis confirmed this observation (Figure S18, Supporting Information, section 14). Compared to the FTIR spectrum of the free-standing film, the thermally treated sample shows small differences in vibration bands. New weak bands at 2500, 1500 and 1150 cm^{-1} could be denoted, possibly due to a slight oxidation of the film. Overall, these results confirm that the thioether-based membrane prepared via the novel VIP method bear a highly dense and hydrophilic network thermally stable until at least 150 °C.

Membrane performance

A series of retention tests were conducted on the Al-SiM/TE membrane using aqueous solution of Brilliant Yellow (BY, 625 g mol^{-1}), Rhodamine B (RB, 479 g mol^{-1}) and an ethanolic solution of Sudan Black B (SBB, 457 g mol^{-1}). The results are given in Table 1. Both aqueous solutions result in high retentions values, $99 \pm 0.4\%$ for BY and $93 \pm 7\%$ for RB. However, SBB retention in ethanol averaged to $50 \pm 2\%$ which can be attributed to the neutral character of the SBB dye as compared to the charged BY or RB. This along with being impermeable to apolar solvents indicates that the Al-SiM/TE membrane bears a dense charged surface. Thus, we expect that the Al-SiM/TE membranes can find use in removal of dyes from water. Table S4 compares the retention performance vs. water permeability of the thioether-based nanofiltration membrane prepared in this work, with data from the open literature. For the sake of relevant comparison, only organically grafted- γ -alumina membranes were considered in this table. Indeed, the porous

ceramic support structure (pore diameter, porosity, architecture) play a strong role on the resistance to the solvent transport as reported in our previous work.⁴² Compared to the literature, the thioether-based nanofiltration membrane present promising retention performance (PEG MWCO ~ 700 instead of 2800 Da) with an acceptable water permeability ($\sim 0.6 \text{ L m}^{-2} \text{ h}^{-1} \text{ bar}^{-1}$). To enhance the membrane permeability, our future research will focus on the adaptation of the membrane structure (intrinsic microporosity), and support (to decrease the resistance to the water flux).

Table 1. Solute rejection tests performed on the Al-SiM/TE membrane. The tests were performed under constant pressure (11 bar), using nitrogen gas, and stirring 700 – 800 rpm. Each test was reproduced three times of which the presented retention is the average and the error refers to the standard deviation from the average value of 3 samples.

Solute	Solvent	Charge	M_w (g mol ⁻¹)	Retention (%)
Brilliant Yellow	Water	Negative	625	100 ± 0.4
Rhodamine B	Water	Positive	479	93 ± 7
Sudan Black B	Ethanol	Neutral	457	50 ± 2

Conclusions

A “click” reaction approach within a novel liquid-vapor IP method was used to prepare ultrathin selective thioether-based cross-linked NF membranes. Here, we report for the first time the combination of “click” chemistry with interfacial polymerization in membrane preparation. In addition to that, we show the formation via means of “click” chemistry on a porous ceramic support and formation of a hybrid system, which in the best of our knowledge has never been

1
2
3 reported in literature before. Typically, LIP methodologies used in membrane technology rely on
4 a biphasic liquid system, however our novel liquid-vapor system relies on a single
5 environmentally friendly solvent and minimal reactant usage. The monomer amounts used in this
6 work are very small (from 0.05 to 0.2 wt.%) when compared to concentrations of a typical IP
7 procedure (from 1 to 3 wt.%).⁶ We demonstrated, via spectroscopic and solvent permeation tests,
8 that the thioether layer exhibits high thermal (150°C for two days) and chemical stability
9 (ethanol, hexane, toluene).
10
11
12
13
14
15
16
17
18

19 Preliminary nanofiltration tests show permeabilities of 0.6 and 0.5 L m⁻² h⁻¹ bar⁻¹ in water and
20 ethanol, respectively with a PEG MWCO of 700 g mol⁻¹ as well as good retention of charged
21 dyes in water. The membrane was found to be impermeable yet stable to two apolar solvents,
22 toluene and hexane. Based on this proof-of-concept, the development of thioether-based cross-
23 linked networks can be expanded to a variety of NF and separation applications.¹⁶ The liquid-
24 vapor interfacial polymerization method presented is a highly effective and facile method which
25 shows significant advantages over the liquid-liquid IP method.
