Welcome Messages

TERMIS EU 2019 Chairs

Dear TERMIS EU 2019 Participants,

We are pleased to welcome you to TERMIS EU 2019 meeting, 27th to the 31st of May 2019, Rhodes, Greece. The theme of the meeting is ‘Tissue Engineering Therapies: From concept to clinical translation and commercialisation’. The programme of the TERMIS EU 2019 includes several symposia in tissue engineering and regenerative medicine tools, technologies and discoveries that aspire to revolutionise healthcare with their reparative capacity.

The TERMIS EU 2019 meeting is held at Rhodes, Greece. Vast sandy beaches with emerald waters, bright green hills and valleys with exceptionally diverse flora and fauna, timeless and traditional villages and cosmopolitan and modern city centre, all bathed in the light of the god Helios, her ancient patron, Rhodes, the Island of Knights, is a place with spectacular natural beauty and abundant history and culture. Rhodes is an everlasting mosaic of cultures and civilisations, where Aegean meets Middle East, where Byzantines, Greeks, Venetians and Turks left something to remember them by. Rhodes hosts the mythical Colossus of Rhodes, one of the Seven Wonders of the Ancient World. The Medieval Old Town of the City of Rhodes is listed as a UNESCO World Heritage site.

Enjoy the meeting and celebrate with us science at its best.

Dimitrios I. Zeugolis, PhD
Conference Chair

Maria Chatzinikolaidou, PhD
Conference Programme Chair
TERMIS Global President

Dear TERMIS EU 2019 Participants,

TERMIS is the most prominent organisation in the field of tissue engineering and regenerative medicine globally. TERMIS promotes education, research, innovation, clinical translation and social responsibility within the field of tissue engineering and regenerative medicine through regular meetings, training courses, scientific and lay publications, outreach activities and other forms of communication. TERMIS also provides an international forum for the informed discussion of challenges and achievements of tissue engineering therapies.

TERMIS is a Not-for-profit Society with three chapters. TERMIS functions through volunteers for our governance, who receive no financial compensation and who dedicate time and finances (directly or indirectly) to run and improve our society. There are numerous committees that report into these governance structures and without these volunteers the society could not function. I would like to take this opportunity to thank all our TERMIS officers that make TERMIS what it is today and will shape its future. Due to this strong volunteer network of TERMIS officers, TERMIS has only one full time employee, Sarah Wilburn. Sarah has just returned from maternity leave and on behalf of our society I wish her many happy years of parenthood and look forward to working with her again soon.

Let Rhodes, with one of the Seven Wonders of the Ancient World stimulate your imagination and inspire creativity. Listen, learn, educate, volunteer. Network, Socialise, enjoy. Thank you Maria and Dimitrios for hosting us.

Prof R Geoff Richards
TERMIS EU President

Dear TERMIS EU 2019 Conference Participants,

Welcome to the 10th TERMIS EU meeting! We are delighted to welcome so many participants. Thanks to the great efforts of Dimitrios Zeugolis and Maria Chatzinikolaидou, we can enjoy a very interesting programme that covers a diverse range of topics, from basic research to clinical and commercial applications for many different diseases.

There are specific activities and sessions aimed at young investigators. I encourage all PhD students and junior postdocs from academia and industry to join as many of these events as possible, gain knowledge from different aspects of the field (not only your own topic) and build your network. We would also like to thank all sponsors, without whom the meeting would not have been possible and encourage everyone to visit their booths during the breaks.

In the coming 5 days, let’s learn about the recent advancements in science and technology related to Tissue Engineering and Regenerative Medicine. We hope you will meet many old and new friends, discuss science and be inspired.

Enjoy the conference and we hope to see you in Manchester next year!

On behalf of the TERMIS EU Council,

Prof Dr Gerjo van Osch
Dear TERMIS EU 2019 Participants,

This year Russia has been selected as the Guest Nation at TERMIS EU 2019. We are truly honoured for this recognition. In the last decade, Russia has become an active player in the field of tissue engineering and regenerative medicine, and the amount of corresponding publications and clinical trials annually increases. Due to historical background, tissue engineering and regenerative medicine in Russia differ from other countries and are strongly connected with physics, material science, and mathematics. The goals of research teams cover the main areas of interest in tissue engineering and regenerative medicine: from searching for stem cell niches \textit{in vivo} to engineering them \textit{in vitro}; from triggering regeneration in damaged tissues to engineering tissues and organs; from gene therapy to cell therapy; from scaffolding to 3D bioprinting. New educational programs on tissue engineering and regenerative medicine are opened at top Russian universities and aim to give birth to the new generation of scientists able to create non-trivial approaches. It is worth mentioning that the Russian government has started to create the required environment to enhance research in this field and its clinical translation by organizing Russian Foundation for Basic Research and Russian Science Foundation and passing the new law regulating the production of biomedical cell products and acting from 2017. New companies focusing on cell-based products and tissue engineering technologies are appearing and introducing them into clinical practice.

We are looking forward to making new friends and collaborations.

On behalf of Russia,

Prof Peter Timashev

PeriCam PSI
The PeriCam PSI uses Laser Speckle Contrast Analysis (LASCA) to measure perfusion. This provides fast, high resolution perfusion images. The PeriCam PSI NR offers a flexible solution with resolutions up to 100 µm/pixel. For extra high resolution needs, for example imaging of the paws only, the PeriCam PSI HR has a resolution of 20 µm/pixel.

Some highlights of the PeriCam PSI:
- Real time recording of the perfusion
- High spatial and temporal resolution
- Advanced user-friendly software for acquisition and analysis
- Imager head easy to maneuver due to premium instrument arm with ball head mount
- Easily create regions of interest (ROI) with automatic background removal
- Include multi-day measurements in the same recording and instantly plot perfusion change over time

Hind limb ischemia (HLI) model
Human vessels can remodel as a response to different stimuli. Understanding the underlying processes angiogenesis (proliferation of capillaries) and arteriogenesis (enlargement of preexisting arterioles) could potentially result in better treatment options for patients suffering from clinical conditions characterized by insufficient blood supply (e.g. peripheral arterial disease). For this purpose, many researchers use the hind limb ischemia model, an animal model in which ischemia is produced by femoral artery ligation. The PeriCam PSI provides high resolution, high quality perfusion images recorded in real-time, with advanced user-friendly software for acquisition and analysis, an ideal instrument to confirm induction of ischemia and to follow changes in hind limb perfusion over time.

Case: hydrogel treatment in a rat model
In a study at the University of California San Diego¹, hind limb ischemia was induced in Female Sprague Dawley rats by removing a 2 cm segment of the femoral artery and vein. Decellularized extracellular matrix-based hydrogels were tested as a treatment. The hydrogels were injected one week post-surgery and perfusion was monitored regularly using the PeriCam PSI for up to 35 days post-injection. Due to the fast nature of the measurements, perfusion could be monitored dynamically during anesthesia. This enabled determination of a new parameter called perfusion kinetics ratio, which gives additional insight into the health of the vascular network by measuring the ability to transition through a change in cardiac output. Both the hind limb perfusion and the perfusion kinetics showed significant improvement with the treatment.

YOUR NEEDS ARE UNIQUE, 
SO ARE OUR BIOFABRICATION SOLUTIONS

The 3D Discovery™ Evolution is the ultimate biofabrication platform intended for both experienced scientists and those who are taking their first step in 3D Bioprinting.

SEVEN PRINTHEADS
Among numerous printing technologies available, seven can be installed and used simultaneously to build multimaterial and multiscalar 3D constructs.

TECHNOLOGY CONVERGENCE
The combination of extrusion (inkjet, pneumatic, piston-driven, thermoplastic dispensing) and electrospinning writing (melt or solution) provides unprecedented control at the micro-scale.

FULLY MODULAR
Biohazard cabinets, climate control units, light sources for proteinized gelation, plasma pens, nebulizers, individual temperature control systems, or cameras for inline monitoring can be integrated.

EOLUTIVE
The 3D Discovery™ Evolution will accompany your scientific journey while constantly adapting to new needs. Get your bioprinter now and start building your biofabrication platform piece by piece.

CUSTOMIZATION
The current offering does not meet your requirements? Our dedicated team will engineer solutions tailored to your specific needs.

FLEXIBLE
Tissue engineering, regenerative & personalized medicine, pharma, medical device industry, cosmetics, drug discovery, and many other applications are using our technology to their advantage.

Clinically Relevant Mesenchymal Stem Cell Populations for Research

“We offer unique stem cell populations within a clinically relevant age range and with clinical presentations”

Mesenchymal stem cells, MSCs, or skeletal stem cells, of bone marrow origin, have been used as research tools for decades and within the past 10 years progressed to hundreds of clinical trials for various regenerative and immunomodulatory approaches. The MSC research field is expanding rapidly, however the outcomes of various in vitro and in vivo studies are not directly comparable due to variability in the stem cell source used, purity, or even irrelevant donor selection.

We offer heterogeneous populations of MSCs, from osteoarthritic donor cohorts (with other orthopaedic cohorts in the pipeline), for biologics and biomaterial testing.

Our stem cells offer the following key advantages:

- Clinically relevant age range for testing therapeutics/biomaterials designed for the elderly, adults or adolescents
- Donors with clinical presentations – osteoarthritis, as a suitable model for relevant drug/biomaterial testing
- Early passages and guaranteed cell expansion – P2 stocks, >10 population doublings under optimal conditions
- Detailed flow cytometric analysis – for expression of common mesenchymal stem/progenitor cell markers, including for STRO-1, CD73, CD90, CD105 and lack of CD45
- Multipotency – tested for osteo-, chondro- and adipogenic differentiation in vitro
- Pathogen free – HBV/HCV/HIV, bacteria, mycoplasma and fungi free

EBERS MEDICAL TECHNOLOGY S.L.

EBERS is a Spanish company with two main business lines:

1. Laboratory equipment and plasticware for tissue engineering, 3D cell culture and biomaterials testing applications.

EBERS develops, manufactures and sells bioreactors and culture chambers for tissue engineering, 3D cell culture applications and biomaterials testing.

A wide range of bioreactors is available, based on the application of controlled flow profiles on the samples, mechanical stimulation conditions and electrical stimulation, among other stimuli. Our bioreactors are adapted to work with tissue and organ samples of variable size and geometry and we offer specific solutions for a wide range of applications, such as, e.g., bone, cartilage, tendon, ligament, blood vessels, skin, airway and large organs such as liver and kidney.

In addition, we also commercialize non-invasive optical oxygen sensors and microfluidic chips able to generate physiological environments involving flow, shear stress, gradients of chemicals and dissolved gases and epithelial-like conditions.

2. Ex vivo solid organ preservation systems with applications in transplantation and solid organ regeneration.

EBERS has developed a portable perfusion system for ex vivo preservation of kidney and liver under physiological conditions. This technology improves the preservation conditions of organs for transplantation: extension of preservation times, enlargement of donor pool, better compatibility with suboptimal organs, objective assessment of organ function and viability. Furthermore, the same product can be used in organ regeneration applications, including de- and re-cellularization protocols, cell culture, organ maturation and function assessment tasks.

Spraybase® Melt Electrospinning Instrument

Interested in Creating 3D Structures with a Low Micron Fiber Diameter?

Technology: Melt Electrospinning is a solvent-free technology bridging the gap between current additive manufacturing technologies such as 3D printing and solution Electrospinning.

Low-Micron Size Fibers: Molten Polymer is used to form a fibrous material generating fibers in the range of 5-40 um.

Versatile: Broad range of FDA approved biocompatible polymers such as PCL, PLA and PLGA can be utilised to create 3D scaffolds in a controlled manner.

Ease and Flexibility of Use: The desired profile can be drawn within the control software program which can be used to form simple shapes, paths and convolutions (squares, circles, arcs, spirals etc.)

The first fully optically accessible microfluidic bioreactor for scaffold-based 3D cell culture

The project MOAB has received funding from the European Research Council (ERC) under the European Union’s Horizon 2020 research and innovation programme (grant agreement No 823159)
TEDD Competence Centre is a collaborative innovation platform, dedicated to 3D cell culture technology and organ-like tissue models for drug development, substance testing, personalised and regenerative medicine. We support implementation of the 3R principles through the introduction of validated technologies as an alternative for animal testing.

TEDD is part of Centre for Cell Biology and Tissue Engineering at the Institute of Chemistry and Biotechnology (ICBT), Zurich University of Life Sciences (ZHAW) and a platform of biotechnet Switzerland. TEDD is led by Prof Michael Raghunath and Dr Katarzyna Kopanska.

The TEDD community is composed of partners from academia, clinical medicine and industry. The industrial partners represent the network’s majority with a spectrum from young spin-off company to world player. TEDD Partners cover the entire area of Switzerland and represent all major cities. International partners constitute 30% of all members. Hence, TEDD serves the whole value chain of biotech R&D relevant for 3D tissue engineering, be it ultra-flat 3D monolayer culture, bioprinted tissue constructs, or organoids.

TEDD Competence Centre combines diverse skills through integrative cooperation among the partners to form a powerful and successful network. Regular events and activities at national and international level ensure exchange and progress.

TERMIS EU 2019 Special Sessions, Meetings & Social Events

**Business Plan Competition (BPC)**
The TERMIS EU 2019 BPC will take place on Tuesday, the 28th of May, from 16.00 to 17.30 at Athena Hall.

**Chairs:** Erik Samuelsson, Sweden; Oliver Ball, United Kingdom

**Team 1:** Robin Simsa, Sweden; Theresa Rothenbuecher, Spain

**Team 2:** Jeanne Volatron, France; Nicolas Rousseau, France

**Team 3:** Sarah Tsurkan, Germany

**Team 4:** Julie Rosser, United States of America

**Team 5:** Hans Mattias Larsson, Switzerland

**Against the Motion:** Emily Growney Kalaf, Ireland; James Britton, Ireland; Meletios Nikolaos Doulgkeroglou, Ireland

**Student & Young Investigator Section (SYIS) Debate**
The TERMIS EU 2019 SYIS Debate will take place on Wednesday, the 29th of May, from 16.00 to 17.30 at Athena Hall. This House believes that unblinded peer-review will result in good science.

**Chairs:** David F Williams, United States of America; Diana Gaspar, Ireland; Dilip Thomas, United States of America

**For the Motion:** Carlos J Peniche Silva, Germany; Felor Biniazan, Iran; Parvaiz A Shiekh, India

**Against the Motion:** Emily Growney Kalaf, Ireland; James Britton, Ireland; Meletios Nikolaos Doulgkeroglou, Ireland

**General Assembly**
The TERMIS EU 2019 General Assembly will take place on Wednesday, the 29th of May, from 17.30 to 18.30 at Jupiter Hall. During the General Assembly, the TERMIS EU Council will update you on performed and ongoing activities and on future directions. You are all welcome to attend to help formulate the future of TERMIS EU.

**Debate**
The TERMIS EU 2019 Debate will take place on Wednesday, the 29th of May, from 18.30 to 19.30 at Jupiter Hall. This House believes that the ethical boundaries associated with regenerative medicine procedures should be more rigorously applied than those for conventional pharmacological or medical device technology applications.

**Chair:** David F Williams, United States of America

**For the Motion:** Alicia El Haj, United Kingdom; Stuart B Goodman, United States of America

**Against the Motion:** Anthony Weiss, Australia; Katja Schenke-Layland, Germany
TERMIS Council & Committee Meetings
TERMIS EU Council Meeting, Tuesday, the 28th of May 2019, 07.00-09.00, Alpha Room, Rodos Palace

TERMIS EU Meetings and Sponsorship Committee Meeting, Tuesday, the 28th of May 2019, 09.00-10.00, Alpha Room, Rodos Palace

TERMIS EU Strategic Alliance Committee Meeting, Tuesday, the 28th of May 2019, 11.00-12.00, Alpha Room, Rodos Palace

Social Events
TERMIS EU 2019 Welcome Reception, Monday, the 27th of May 2019, 20.00-23.00, Dome Indoor Pool, Rodos Palace (Including in the registration)

TERMIS EU 2019 Get Together, Tuesday, the 28th of May 2019, 20.00-23.00, Outdoor Pools, Rodos Palace (Including in the registration)

TERMIS EU 2019 SYIS Get Together, Wednesday, the 29th of May 2019, 20.00-23.00, Bamboo Rhodes, 6 Iliadon Street, Ixia, Rhodes

TERMIS EU 2019 Soiree, Thursday, the 30th of May 2019, 20.00-23.00, Outdoor Pools, Rodos Palace (Including in the registration)
TERMIS EU 2019 General Information

Conference Venue
Rodos Palace Hotel (https://www.rodos-palace.gr), Iракlidon Avenue, Ixia, Rhodes, Greece. Telephone: +30 22410 97222. Rodos Palace is ~10.7 Km away from Diagoras Rhodes International Airport.

Podium Presentations
All podium presenters are requested to bring their presentation files (pdf or ppt format), using a USB stick, to the speaker ready room the day before their talk. Please ensure that your videos run properly. No one will be allowed to present from their own computer. All speakers must keep to their allocated presentation time (e.g. Plenary Speakers: 28 min talk + 2 min questions and answers; Invited Speakers: 18 min talk + 2 min questions and answers; Other Speakers: 8 min talk + 2 min questions and answers). Sessions chairs are instructed to not allow speakers run over time.

Poster Presentations
The poster boards are ordered in numerical order. Please use your allocated poster board number. Posters will be displayed for the duration of the meeting. Organisers do not take responsibility for posters remaining at the end of the conference.

TERMIS EU 2019 Charity
This year, no conference bags will be distributed among participants. Instead, TERMIS EU 2019 will make a donation to Ark of the World, a voluntary non-profit organisation of mother and child protection (https://www.kivotostoukosmou.org/en/).

Name Badge
Your name badge is your admission pass to TERMIS EU 2019 scientific sessions, exhibitions, coffee and lunch breaks, Welcome Reception, Get Together and Soiree. Without your name badge, admission will not be allowed. Accompanied persons who have not registered will be able to purchase tickets for the Welcome Reception, Get Together and Soiree on the date at the venue.

Insurance
The conference organization does not take out insurance to cover any individual against accidents, thefts or other risks.

Currency & Money Exchange
The Euro (€) is the official currency in Greece. There are several banks and cash dispensers on the island. Major international credit cards are accepted in most hotels, shops and restaurants.

Smoking
Smoking is prohibited at the conference venue or in any other public indoor establishment.

Tipping
Service is included in Greece. Tips, however, are given to show appreciation of a good service.

Disclaimer
All podium and poster presentations are the intellectual property of the presenting author and co-workers. All rights are reserved. Abstracts have been edited to fit the one-page limit as per original guidelines. Recording, photographing and/or copying of podium or poster presentations or any other material is strictly forbidden without prior approval of the Conference Chair, Conference Programme Chair and the owner of the material. Further information about disclaimer, can be found here: https://termis.org/eu2019/disclaimer.php

Use of Mobile Phones
Use of mobile phones is not allowed in the lecture halls during sessions. Please be considerate of others by turning off your mobile phone.

TERMIS EU 2019 About Rhodes

Rhodes
Rhodes is the largest island of the Dodecanese complex in Greece. Turquoise bays, wooded valleys and ancient history are abundant in Rhodes. Timeless and traditional villages and cosmopolitan and modern city centres are bathed in the light of the god Helios, Rhodes’s ancient patron. Rhodes is also known as the Island of Knights, after the Knights of Saint John of Jerusalem, who once conquered it. Rhodes is a nexus of cultures and civilizations, where Aegean meets Middle East, where Byzantines, Greeks, Venetians and Turks left something to remember them by. Rhodes hosted the mythical Colossus of Rhodes, one of the Seven Wonders of the Ancient World. The Medieval Old Town of the City of Rhodes is listed as a UNESCO World Heritage site.

Filerimos
Filerimos was built upon the ancient city of Ialyssos, one of the biggest in Rhodes at the time, along with Lindos and Kameiros. Placed on a hill surrounded by trees more than 200 meters high, Filerimos provides a splendid view of the island surrounded by the Aegean Sea. The area today is known for its monastery complemented by structures dating back to the Middle Ages.

Kameiros
An area inhabited since prehistoric times, the city of Kameiros reached the pinnacle of its prosperity alongside Lindos and Ialyssos. It was amphitheatrically built on a hill. At its highest point stood the acropolis, which was unfortified, as was the city itself. On the surrounding hills, ancient burial grounds have been found. In one of the graves was unearthed the famous stele of Crito and Timarista.

Lindos
Widely considered as the most attractive village on the island, it is built amphitheatrically around the foot of the steep rock where the ancient acropolis is located with the Temple of Athena Lindia. The view at more than 100 meters above sea level is exceptional. There are also the ruins of the castle of the Knights and the Byzantine church of St. John covered with 18th century frescoes.

Church of the Virgin of the Burgh
Built around the 14th century, this gothic style church is one of the remnants of the Knights inside the Old City of Rhodes. It can be found at the Jewish Quarter of the town, on its eastern part. This church was the biggest one in the area for years. Nevertheless, since it was heavily damaged during World War II, only a part of it is still intact. The ruins are accessible to anyone who wants to have a glimpse of the past of the island.

Palace of the Grand Master
When you visit the medieval part of the city of Rhodes, you enter via its most imposing building, the Grand Master’s Palace. The castle was originally built in the 14th century, destroyed by an explosion in 1856 and restored in 1939 during the Italian occupation. One of the few buildings of Gothic architecture in the country, it was recognized as a UNESCO World Heritage Site in 1988.

Rita Ibanez
The development of a novel 3D bioprinted smart responsive dressing to treat skin scars  10 min

Joao Quintas Coentro
Replicating and modulating skin fibrosis in vitro: Multi-compartment collagen devices as dual drug delivery vehicles  10 min

Ronaldo do Amaral
Incorporation of platelet-rich plasma into collagen-glycosaminoglycan scaffolds for wound repair  10 min

Sergio Cortez Ghio
A newly developed defined medium for human keratinocyte culture and skin substitute production  10 min

Sharon Claudia Notodihardjo
Gelatin hydrogel with concentrated and refrigerated lyophilized human platelet lysate as full-thickness wound treatment  10 min

Siavash Shariatzadeh
The co-application of freeze-dried amniotic membrane and lacto-n-neotetraose oligosaccharide as an inducer of type 2 immune response for full-thickness wound healing  10 min

Shubhasmin Rana
Impact of polyvinylpyrrolidone on extracellular matrix deposition and cell proliferation of WS1 fibroblast  10 min

Sacha Salameh
A new model of vascularized reconstructed skin  10 min

Lunch Break  13.00-14.00

Monday, 27th of May 2019
Registration & Setup  09.00-11.00
S4. Biomaterials  Delphi 11.00-13.00
Chairs: Jons Hilborn, Stefan Scheurer, Giovanna Della Porta

Jons Hilborn – Invited
Extracellular matrix derived components as building blocks for tough hydrogels  20 min

Dimitria B Camasao
The effect of elastin-like recombinant on SMCs behavior and mechanical properties of tubular collagen gel-based scaffolds  10 min

Anna Lapomarda
Fabrication and characterization of porous pectin-based scaffolds crosslinked by GPTMS for tissue engineering applications  10 min

Simone Russo
Tissue engineering scaffolding: Computer aided in-vitro degradation model  10 min

Betul Aldemir Dikici
Boosting biological performance of multiscale porous scaffolds by in vitro generated extracellular matrix decoration  10 min

Roman Chernozem  10 min
Surface modification of biodegradable scaffolds via diazonium chemistry for tissue engineering: A piezoresponse and wettability study
Polina Y Bikmulina
Low-intensity LED irradiation improves cell viability in 3D scaffolds
Yue Wang
Cell-selective peptide functionalized polysaccharide-collagen hybrid material for medical application
Mohammad Nauman Jalil
Evaluating the design and fabrication of tissue engineering scaffolds based on triply periodic minimal surfaces
Nicholas Welch
Medical device coatings to mitigate the foreign body response
Edurne Marin
Fabrication of manganese dioxide (MnO2)-loaded polymer capsules to prevent oxidative stress
**Lunch Break**

A novel composite of nanohydroxyapatite (nHAp), synthetic polymer (PLA-PEG) and bone morphogenetic protein 2 (rhBMP-2) for bone regeneration

**Lunch Break**

### Monday, 27th of May 2019

| **Registration & Setup** | 09.00-11.00 |
| **S6. Microscopy & Imaging** | **Roses B** 11.00-13.00 |
| Chairs: Martin Leahy, Daniel J Stuckey | **Martin Leahy – Invited** |

**Nanosensitive imaging of tissue constructs and cells**

- Eva Brauchle
  - Characterization of endometriosis and comparison to endometrial cancer using Raman microspectroscopy
  - 10 min
- Karin Schutze
  - Raman trapping microscopy for label-free and fast cell analysis in 2D-cell cultures, 3D tissue models and within liquid blood products
  - 10 min
- Claudio Conci
  - Miniaturized imaging window for intravital nonlinear microscopy
  - 10 min
- Hans van Oosterwyck
  - Quantitative imaging of the cell mechanical environment of 3D multicellular systems
  - 10 min
- Niloufar Khosravi
  - A close look at peri-implant wound healing inside the living body in real-time
  - 10 min
- Petra Wolint
  - Novel multimodal imaging based quantitative assessment approach to evaluate angiogenesis and vascular architecture: Combined MRI and MicroCT imaging in the CAM assay
  - 10 min
- Stephen Patrick
  - Radio-metal cross-linking of alginate hydrogels for non-invasive imaging
  - 10 min
- Olga Janouskova
  - Study of true morphological structure of macroporous hydrogel scaffolds using SEM and LSCM – Impact to cell growth
  - 10 min
- Tugba Cebe
  - Quantification of collagen fibre structure in osteogenesis imperfecta using second harmonic generation imaging on polycaprolactone scaffold
  - 10 min
- Valentina Parodi
  - Characterization of stem cell differentiation in a 3D nichoid scaffold through label-free multimodal microscopy
  - 10 min

**Lunch Break**

13.00-14.00
### Monday, 27th of May 2019

### Tuesday, 28th of May 2019

#### S35. Eye
**Chairs:** Mark Ahearne, Samantha L Wilson  
**Roses B**  
**11.00-13.00**

- **Heli Skottman – Invited**  
  Modeling of limbal stem cell differentiation using human pluripotent stem cells and tissue engineering  
  **20 min**

- **Ilida Ortega Asencio – Invited**  
  Simplifying corneal regeneration via the use of pliable tissue delivery microfabricated membranes  
  **20 min**

- **May Griffith – Invited**  
  Designing biosynthetic corneal implants for clinical application  
  **20 min**

- **Iriczalli Cruz-Maya**  
  In vitro characterization of keratin added fibers for cornea regeneration  
  **10 min**

- **Tahereh Tayebi**  
  Biofabrication of corneal endothelial grafts through culturing the human corneal endothelial cells on nanochitosan-polycaprolactone membrane  
  **10 min**

- **Laura Koivusalo**  
  Tissue adhesive hydrogels for corneal epithelium and stromal regeneration  
  **10 min**

- **Mikhail Tsurkan**  
  Multicomponent hydrogel materials as bioreactors for tissues production  
  **10 min**

- **Rachel McCormick**  
  Designing a novel bioengineered substrate as a treatment for AMD  
  **10 min**

- **Sophia Masterton**  
  Mechanical regulation of the corneal epithelium  
  **10 min**

**Lunch Break & SYIS Meet the Mentor 1 at Gallery Restaurant**  
**13.00-14.00**

#### S36. Extracellular Vesicles
**Chairs:** Catherine Le Visage, Halima Kerdjoudj  
**Athena**  
**11.00-13.00**

- **Wolfgang Holnthoner – Invited**  
  Extracellular vesicles in blood and lymphatic vasculature  
  **20 min**

- **Johannes Grillari – Invited**  
  Systemic environment, extracellular vesicles and miRNAs in aging: Impact on cell based therapies?  
  **20 min**

- **Mario Gimona – Invited**  
  Development and GMP-compliant manufacturing of EV therapeutics: From preclinical research to clinical application  
  **20 min**

- **Florence Gazeau – Invited**  
  Engineering of extracellular vesicles for drug delivery  
  **20 min**

- **Andrea De Luna**  
  Coagulation influences properties of extracellular vesicles isolated from autologous blood derived products  
  **10 min**

- **Alexander Otahal**  
  Efficient clearance of lipoproteins from anti-coagulated and native blood-derived products to yield pure extracellular vesicle preparations  
  **10 min**

- **Callum Conroy**  
  **10 min**
Size exclusion chromatography is an efficient method of isolating extracellular vesicles from a novel human umbilical cord MSC population

Coffee Break & Poster Session 4 at Dome Indoor Pool  15.30-16.00

| Tuesday, 28th of May 2019 | S39. Controlling Cell Fate | Nafsika  
| | Chairs: Joao Mano, Clara R Correia | 14.00-15.30 |
| | Manual Salmeron-Sanchez – Invited | 20 min |
| | Engineered microenvironments for stem cell engineering | |
| | Insung S Choi – Invited | 20 min |
| | Cytoprotective single-cell nanoencapsulation | |
| | Ludmila Buravkova | 10 min |
| | Growth-arrested adipose-tissue stromal cells and “physiological” hypoxia enhance ex vivo expansion of hematopoietic cells | |
| | Mahetab Amer | 10 min |
| | Designing microparticles for tissue engineering: Varying surface topography of polymeric microparticles influences mesenchymal stem cell fate | |
| | Lisanne Karbaat | 10 min |
| | Prolonged intra-articular retention of mesenchymal stem cells by advanced microencapsulation for regenerative joint therapies | |
| | Jorge Oliver De La Cruz | 10 min |
| | Dimensionality dictates substrate mechanics effects on adipogenesis by controlling Yap phosphorylation through cell spreading | |
| | Heonuk Jeong | 10 min |
| | Osteoclast differentiation of murine precursor cells on microgroove patterned substrate | |
| Coffee Break & Poster Session 4 at Dome Indoor Pool | 15.30-16.00 |

| Tuesday, 28th of May 2019 | S40. Cartilage & Osteoarthritis | Delphi  
| | Chairs: Claire Vinatier, Anne Des Rieux | 14.00-15.30 |
| | Farida Djouad – Invited | 20 min |
| | Advances in mesenchymal stem cell therapy for osteoarthritis: From the cell to its extracellular vesicles | |
| | Catherine le Visage – Invited | 20 min |
| | Mesenchymal stem cell encapsulation in alginate micro-particles for intra-articular injection in osteoarthritis | |
| | Michelle Teunissen | 10 min |
| | The catabolic-to-anabolic shift in the osteoarthritic cartilage after knee joint distraction in dogs occurs after the distraction period | |

Towards understanding why nanoclays are osteogenic
Priscila Melo
Use of short phosphate glass fibre reinforcement to promote bone mineralisation on PLLA composites
Priscilla Briquez
Engineered bridge proteins with dual affinities for bone morphogenetic protein (BMP)-2 and collagen improve controlled release of BMP-2 for bone regeneration

Coffee Break & Poster Session 4 at Dome Indoor Pool  15.30-16.00

Tuesday, 28th of May 2019
S44. Muscle Chairs: Ori Bar-Nur, Thomas Rando  Jupiter  16.00-17.30
Ori Bar-Nur – Invited
Modeling myogenesis in vitro using directly reprogramed induced myogenic progenitor cells  20 min
Thomas Rando – Invited
Exercise enhances the treatment of volumetric muscle loss by stem cell transplantation  20 min
Raziel Hamami
The use of skeletal muscle-derived pericytes in tissue engineering of skeletal muscle graft based on 3D pluronic-fibrinogen (FF-127) hydrogel environment  10 min
Arturo Ibanez-Fonseca
Skeletal muscle healing mediated by ELR-based hydrogels  10 min
Soo Jung Chae
Development of anisotropic fibrous bundle-like PCL structure for muscle tissue regeneration  10 min
Kirankumar Gudagudi
Comparison and blended protocol to induce quiescence in vitro in primary human myoblasts  10 min
Michela Pozzobon
Stimulation of muscle regeneration by extracellular vesicles  10 min
**Coffee Break & Poster Session 5 at Dome Indoor Pool**  
17.30-18.00

### Tuesday, 28th of May 2019

#### S45. Organoids

**Chairs:** Ralph Mueller, Marina Rubert, Daniel J. Kelly, Queralt Vallmajo-Martín  
**Nefeli 16.00-17.30**

- **Debby Gawlitta – Invited**  
  Skeletal vascularized organoids from patient-derived cells  
  **20 min**
- **Marina Rubert – Invited**  
  From cell-laden bone tissue engineering to personalized bone organoids  
  **20 min**
- **Ralph Mueller – Invited**  
  Micro-3D printing of osteocyte organoid models  
  **20 min**
- **Louis Penning – Invited**  
  Long-term survival of transplanted autologous canine liver organoids in a COMMD1 deficient dog model of metabolic liver disease like Wilson’s disease  
  **20 min**
- **Ross Burdis**  
  High-throughput biofabrication of organoids for osteochondral tissue engineering  
  **10 min**

#### S46. Biophysical Stimuli

**Chairs:** Bernd Rolauffs, Martin Stoddart  
**Nafsika 16.00-17.30**

- **Martin Stoddart – Invited**  
  Role of kinematic load on cell behavior  
  **20 min**
- **Bernd Rolauffs – Invited**  
  Using biophysical cues for engineering cell morphology and function  
  **20 min**
- **Eoin O'Cearbhaill – Invited**  
  Optimising medical device tissue adhesion and integration through mechanical and surface topographical methods  
  **20 min**
- **Monica Soncini**  
  Mechanotransduction at the nuclear pore complex investigated at the molecular level: The role of SUN1  
  **10 min**
- **Farhad Chariyev-Prinz**  
  Hydrogel stiffness regulates the response of mesenchymal stem cells to dynamic loading  
  **10 min**
- **Morgane Rabineau**  
  Opening of chromatin in cancer cells by switching substrate elasticity  
  **10 min**

#### S47. Discovery Centre

**Chairs:** Rui L Reis, Jonathan Knowles, Carlos Guimaraes  
**Delphi 16.00-17.30**

- **Jonathan Knowles – Invited**  
  Strategies for peripheral and central nerve repair  
  **20 min**
- **Ricardo A Pires – Invited**  
  ECM mimics using modular minimalistic supramolecular systems  
  **20 min**

#### S75. Inflammation & Immunity
**Chairs:** Julia Kzhyshkowska, Alina Vladescu  
**Location:** Nafsika  
**Time:** 16.00-17.30

- **Nihal Engin Vrana – Invited**  
  Immunoprofiling in tissue engineering and immune assisted tissue engineering via macrophage containing scaffolds  
  20 min

- **Philippe Lavalle – Invited**  
  Immunomodulatory programming and antimicrobial activity by new biomaterials  
  20 min

- **Julia Kzhyshkowska – Invited**  
  Programming of macrophages as the immunomodulatory approach in implantation  
  20 min

- **Tijana Sustersic**  
  Monocyte behaviour under perfusion conditions for development of granuloma on-a-chip  
  10 min

- **Julien Barthes**  
  Gelatin hydrogel as surface coating for immunomodulation and tissue engineering  
  10 min

- **Arban Uka**  
  Computer assisted analysis for quantification of macrophages response to biomaterials  
  10 min

**Coffee Break & General Assembly**  
**Time:** 17.30-18.30

---

#### S76. Innovation, Commercialisation, Translation
**Chairs:** Patrina SP Poh, Navid Khani  
**Location:** Delphi  
**Time:** 16.00-17.30

- **Navid Khani – Invited**  
  Transforming scaffold designs from university to industry – A bench-to-bedside perspective  
  20 min

- **Ineke Slaper-Cortenbach – Invited**  
  International standardization and electronic coding of the terminology for regenerated tissue products  
  20 min

- **Simon Champ – Invited**  
  Innovation and commercialisation in the field of regenerative medicine: Learning from the past and lessons for the future  
  20 min

- **Hans Joerg Meisel – Invited**  
  Commercialization of tissue engineering products - A user’s clinical perspective  
  20 min

- **Dmytro Zubov**  
  Tissue-engineered bone equivalent application for treatment of combat-related bone defects  
  10 min

**Coffee Break & General Assembly**  
**Time:** 17.30-18.30

**11.00-13.00**

**Jose Miguel Garcia-Martín – Invited**  
Environmentally-friendly coatings with antibacterial properties  
**20 min**

**Lia Rimondini – Invited**  
No antibiotics biomaterials functionalization to prevent and fight implants associated infections  
**20 min**

**Ludivine Hugoni**  
**10 min**
Poly(arginine) grafted to biphosphonated dendrons: A novel strategy to design antimicrobial coatings for biomaterial applications

Mireia Hoyos-Nogues
Triple function in one coating: Towards anti-adhesive, bactericidal, and cell instructive medical implants

Stijn Rotman
Antibiotic loaded poly(epsilon-caprolactone) microspheres functionalized with poly(aspartic acid) as bone targeting delivery system to treat infection

Eleanor Porges
Stable encapsulation of rifampicin in polymersome nanoparticles for delivery to intracellular bacteria

Tatiana Padrao
Innovative bone substitute to prevent device-associated infections

Varvara Gribova
Hyaluronic acid hydrogels with prolonged antibacterial activity

Ada Vernet Crua
Green synthesis of a synergetic structure of tellurium nanowires and metallic nanoparticles for biomedical applications

Merve Perpelek
Novel helix aspersa extract loaded chitosan scaffolds for hard tissue regeneration

Lunch Break 13.00-14.00

Thursday, 30th of May 2019
S93. Nanomaterials
Chairs: Piergiorgio Gentile, Irene Carmagnola

Joao Borges – Invited
Bottom-up layer-by-layer assembly technology to process nanostructured multifunctional biomaterials across multiple length scales for tissue engineering and regenerative medicine strategies 20 min

Piergiorgio Gentile – Invited
Bioactive nanocoatings via layer-by-layer technique to improve antibacterial properties of polymeric membranes for guided bone regeneration 20 min

Jeanne Volatron
Long term fate of iron oxide nanoparticles in the organism 10 min

Marcia T Tavares
Bioactive mesoporous silica nanoparticles for stem cell differentiation in bone regeneration 10 min

Mariana Carvalho
Targeting colorectal cancer using highly specific peptide-modified dendrimer nanoparticles 10 min

Oscar Castano
Angiogenic signaling in bone 3D scaffolds through calcium phosphate ion release nanotechnology 10 min

Ruby Singh
Multilayer, multifunctional core-shell airbrushed nanofiber membrane for periodontal regeneration 10 min

Coffee Break & Poster Session 9 at Dome Indoor Pool 15.30-16.00
Scaffolding and bioprinting via advanced laser technologies
Raphael Wenger
Multi-nozzle inkjet and its potential for the industrialization of bioprinting 10 min

Coffee Break & Poster Session 9 at Dome Indoor Pool 15.30-16.00

Thursday, 30th of May 2019

S100. Tendon, Ligament, Enthesis
Chairs: Manuela E Gomes, Denitsa Docheva, Stefanie Korntner

14.00-15.30

Denitsa Docheva – Invited
Translation of basic tendon science into clinical practice 20 min

David Musson – Invited
Materials and growth factors for rotator cuff repair 20 min

Angela Imere
3D bioprinted/electrospun bilayer biomembrane for regeneration of tendon synovial sheath 10 min

Adrian Djalali-Cuevas
Evaluation of tendon and skin fibroblasts for scaffold-free tendon tissue engineering using macromolecular crowding technology 10 min

Barbara Barboni
Innovation in amniotic epithelial cell-based tendon regenerative protocols 10 min

Manuel Delgado Caceres
Deciphering tendons: A systematic review of tendon-specific genes and uncovering the roles of tenomodulin in tendon healing 10 min

Rui MA Domingues
Magneto-mechanical actuation of magnetic responsive fibrous scaffolds boosts tenogenic commitment of human adipose stem cells 10 min

Coffee Break & Poster Session 9 at Dome Indoor Pool 15.30-16.00

Thursday, 30th of May 2019

S101. Vascularisation & Angiogenesis
Chairs: David O'Connor, Laura Turco, Alicia Fernandez Colino

14.00-15.30

Mohammad Hadi Farjoo
Human placenta derived membrane is a favourable natural biomaterial for vascular tissue engineering 10 min

Nasim Salehi-Nik
What controls endothelial sprouting? Interstitial flow vs. shear stress 10 min

Eline van Haafken
Cyclic stretch and shear stress differentially modulate early vascular tissue regeneration 10 min

Meenakshi Kamaraj
3D printed vascular channels and their maturation by flow stimulated bioreactor 10 min

Iris Pennings
Differentiation of endothelial cells and smooth muscle cells in bi-layered vascular grafts under flow perfusion 10 min

Karl H Schneider
Human placenta ECM hydrogels for vascular graft surface coating to improve cell seeding efficiency in a bioreactor system 10 min

Future TERMIS Meetings

TERMIS EU 2020
Symposia

Symposium Title
(Bio)artificial organs and tissue engineering for the treatment of chronic diseases

Symposium Organisers
Dimitrios Stamatialis, Chair of Bioartificial organs, Department of Biomaterials Science and Technology, TechMed Institute of Biomedical Technology and Technical Medicine, University of Twente, The Netherlands
Email: d.stamatialis@utwente.nl

Nuno Neves, I3Bs-Research Institute 3B’s on Biomaterials, Biodegradables and Biomimetics, University of Minho, Portugal
Email: nuno@i3bs.uminho.pt

Symposium Summary
In the coming years, due to the aging of the population and the low availability of donor organs there will be urgent need for assisting, mimicking or replacing failing patient organs. These organs can be obtained either by artificial means (ESAO members contributed enormously for the progress of this field) or by bioartificial means, by combining biomaterials and cells to fully overcome organ failure. In addition, such combined devices could be used as a valuable alternative to animal trials to assess the safety and efficacy profile of new drugs. The challenges (scientific and technological) are big. There is need for new biomaterials, need for better understanding and tailoring of the biomaterial - cell / tissue interaction, better immune protection, surface bioactivity, mass transfer, as well as, development of new concepts and designs. The complexity increases significantly from artificial to bioartificial organs, and the engineering and regulatory demands increase further for implantable organs. The development of new Advanced Therapy Medicinal Products based in concepts of Tissue Engineering and Regenerative Medicine create opportunities to transpose those concepts into bioartificial organs, enabling exploring synergies at the interfaces between those scientific and translational areas. Indeed, although having different approaches and goals, both areas share many of the challenges posed by the tools used (biomaterials, cells) and by the regulatory framework. In this symposium, we will present cutting edge research of members of the European Society for Artificial Organs showcasing the progress in Bioartificial Organs and Tissue Engineering for the treatment of chronic diseases.
Symposium Title
The discoveries CTR (DCTR) - The discoveries centre for regenerative and precision medicine, an EC Horizon 2020 teaming project

Symposium Organisers
Rui L. Reis, 3B’s Research Group, I3Bs – Research Institute on Biomaterials, Biodegradables and Biomimetics of University of Minho, 3B’s Research Group, Portugal
Email: rgreis@i3bs.uminho.pt

Jonathan Knowles, UCL Eastman Dental Institute, Division of Biomaterials and Tissue Engineering, United Kingdom
Email: j.knowles@ucl.ac.uk

Symposium Summary
The Discoveries Centre for Regenerative and precision Medicine aims to perform world-leading translational research in regenerative and precision medicine, by anchoring research activities of a unique pool of scientific talent, promoting excellence, advanced training at doctoral and post-doctoral levels and clinicians, increasing performance and scientific production, translational research outputs, health-related companies and commercialization strategies that can, in the long-run generate an important economic impact, besides impacting the quality of life of an ageing European population affected by neurodegenerative, cardiovascular and musculoskeletal disorders. This symposium will constitute a forum for the discussion of emerging Regenerative and precision medicine strategies that may provide novel treatments for a number of diseases, including musculoskeletal, cardiovascular and neurodegenerative disorders, among others, as well as on recent advances toward the translation of such therapies for into the clinics.
**Symposium Title**  
3D Printing and Biofabrication: from new technologies to clinical applications

**Symposium Organisers**  
Aleksandr Ovsianikov, Additive Manufacturing Technologies (AMT) Group, Institute of Materials Science and Technology (E308), TU Wien (Technische Universität Wien), Getreidemarkt 9, 1060 Vienna, Austria  
Email: Aleksandr.Ovsianikov@tuwien.ac.at

Email: brunella.grigolo@ior.it

Wojciech Swieszkowski, Biomaterials Group, Materials Design Division, Faculty of Materials Science and Engineering, Warsaw University of Technology, Warsaw, Poland  
Email: wojciech.swieszkowski@pw.edu.pl

**Symposium Summary**  
The field of 3D Printing and Biofabrication has experienced rapid growth in the tissue engineering sector within the recent years. It is gearing towards more and more solutions to develop in vitro 3D models and regenerative therapies. Whereas the creation of more complex and biomimetic 3D models could spur further knowledge on pharmaceutical treatments and developmental processed behind tissue and organ morphogenesis, biofabrication-based regenerative solutions hold the potential to restore tissue anatomy and physiology. In the proposed symposium, we aim to provide a state-of-the-art overview of recent advances in the field of 3D printing and biofabrication.
Symposium Title
A consortium effort toward 3D printed constructs for osteochondral defect repair

Symposium Organisers
Geoff Richards, AO Research Institute Davos (ARI), Clavadelerstrasse 8, 7270 Davos, Switzerland
Email: geoff.richards@aofoundation.org

David Eglin, AO Research Institute Davos (ARI), Clavadelerstrasse 8, 7270 Davos, Switzerland
Email: david.eglin@aofoundation.org

Symposium Summary
Osteochondral defects resulting from traumatic injuries lead to the destruction and damage of articular cartilage and subchondral bone. While there have been numerous attempts to develop tissue engineered constructs and cells-free scaffolds for osteochondral regeneration, there remain significant hurdles for clinical application. Indeed, the fabrication of multi-tissues regenerating constructs based on biomaterials and/or cells remains a challenge due to lack of systemic and rational studies. To address the specific challenges of osteochondral defects, an AO foundation founded a consortium bringing together multidisciplinary expertise in materials, bioprinting, bioreactors, biomechanics, macrophages and animal models. The use of additive manufacturing approaches to produce constructs with precisely controlled internal architecture and the potential for patient specific implants will be explored. In addition, as the immune response and inflammatory environment is known to directly influence the repair tissue produced, the effect of the material combination on macrophage behavior will be investigated.
Symposium Title
Academia to industry: Building the bridge

Symposium Organiser
Pedro Costa, BIOFABICS - 3D Biotissue Analogues, Portugal
Email: pedrocosta22@gmail.com
Dennis Link, BioConnection B.V., Oss, The Netherlands
Email: dennis.link@bioconnection.eu

Symposium Summary
Everybody has great product ideas, but yet only a small percentage of ideas ever get started. The idea of introducing a product into the market seems overwhelming, complicated and very expensive to most people. They don’t know where to start or what to do, so eventually nothing will be done. That is quite a shame, so this symposium should encourage scientists to build this bridge to industry and develop their ideas into successful products. Personal experiences will be shared related to the various stages of creating and leading a start-up and what it takes to develop a product. Also insights will be given related to working in industry compared to an academic career.
Symposium Title
Achilles Twinning H2020 Project – Overcoming specific weaknesses in tendon biology to design advanced regenerative therapies

Symposium Organisers
Manuela E. Gomes, I3Bs – Research Institute on Biomaterials, Biodegradables and Biomimetics of University of Minho, 3B’s Research Group, Portugal
Email: megomes@i3bs.uminho.pt

Denitsa Docheva, Experimental Trauma Surgery, Department of Trauma Surgery, University Regensburg Medical Centre, Germany
Email: denitsa.docheva@klinik.uni-regensburg.de

Symposium Summary
Tendon injuries pose a major burden to healthcare systems given the poor healing ability of tendons. Indeed, tendon repair frequently requires surgical intervention for the application of tissue grafts; however, clinical outcomes are still unsatisfactory. Alternatively, tendon tissue engineering aims at proposing new advanced therapies to promote tendon regeneration through full recovery of tissue functionality. To this end, numerous approaches exist but the development of a successful therapy that can effectively regenerate tendons is highly compromised by the lack of fundamental knowledge concerning the main mechanisms underlying tendon homeostasis, pathology and regeneration. This symposium will constitute a forum for the discussion of current knowledge on the (still poorly understood) molecular mechanisms behind mechanostransduction processes occurring in native tendon development, as well as on recent advances toward the generation of regenerative therapies for tendon.
**Symposium Title**
Additive manufacturing using melt electrowriting

**Symposium Organiser**
Paul D. Dalton, Functional Materials in Medicine and Dentistry, University Clinic Würzburg, Würzburg, Germany
Email: paul.dalton@fmz.uni-wuerzburg.de

**Symposium Summary**
This symposium will be the first one world-wide to focus on an emerging additive manufacturing technology, termed melt electrostatic writing (electrowriting). This technique permits the design of advanced complex biomedical materials with micro-scale features that allows clinically translatable research to be performed in university settings. Recent advances in intuitive software interfaces and scale up systems will lead to an extensively used approach that permits both fundamental polymer processing and manufacture of large-scaled scaffolds. The ability to alter the diameter on demand provides another set of design variable, and the direct writing of medical fibres, including suspended ones, builds on many decades of melt processing for medical devices from the regulatory perspective. The benefit for the biomaterials and TERM community is a robust, reproducible and low-cost manufacturing technology that we predict will become a major additive manufacturing technology by 2025.
Symposium Title
Additive manufacturing with hybrid natural-synthetic materials for tissue engineering

Symposium Organisers
Ana Ferreira-Duarte, School of Engineering, Newcastle University, United Kingdom
Email: ana.ferreira-duarte@ncl.ac.uk

Kenny Dalgarno, School of Engineering, Newcastle University, United Kingdom
Email: kenny.dalgarno@ncl.ac.uk

Symposium Summary
Additive manufacturing has increasingly widespread as a tool to build up complex three-dimensional geometries in the biomedical field. To achieve this, increased demands are placed on the materials and parameters of the manufacturing process and on the performance of the final construct. Considerable effort has been directed toward increasing the precision and control over advanced architectures for regenerative medicine, which can reproduce the complexity and fidelity of biological systems. Biosynthetic polymers are materials that combine natural and synthetic components in order to mimic those properties found in nature. While, additive manufacturing enables the manufacturing of complex geometries, the use of biosynthetic materials allows scaffolds to mimic the versatile and functional properties of biopolymers found in native tissues. This symposium will consider key aspects in biosynthetic materials design and AM processing parameters to enhancing build speed and improving accuracy and functionality for regenerative medicine.
Symposium Title
Advanced therapies of the future for spinal regeneration: The H2020 European iPSpine project

Symposium Organisers
Marianna Tryfonidou, Dept of Clinical Sciences of Companion Animals, Faculty of Veterinary Medicine, Utrecht University, The Netherlands
Email: M.A.Tryfonidou@uu.nl

Jerome Guicheux, INSERM UMRS 1229, Regenerative Medicine and Skeleton (RMeS), Nantes University School of Dental Surgery & Nantes University Hospital, Nantes, France
Email: Jerome.guicheux@inserm.fr

Symposium Summary
Low back pain (LBP) is a leading cause of disability and morbidity worldwide. It is widely accepted that a major contributor to LBP is intervertebral disc degeneration (IDD). These patients receive conservative treatment (e.g. pain relief medication and physiotherapy). When the latter is unsatisfactory, the only option left are invasive and costly surgical interventions. To date, no treatments halt or reverse IDD. The iPSpine consortium was formed to initiate a European-led research effort to identify a future advanced therapeutic strategy that results into a radical new treatment of IDD-induced LBP. With their multi-disciplinary expertise in the development of advanced therapies and their translation from bench to bedside, the aim of the iPSpine team is to investigate and develop a new advanced therapy medicinal product (ATMP) of the future, based on a novel developmental biology-based therapeutic strategy employing pluripotent stem cells (iPSC) and smart biomaterials. The iPSpine consortium will develop and demonstrate Proof-of-concept with the aid of novel and extended knowledge, tools and technology platforms. Hereby, iPSpine has the ambition to make a significant contribution by reducing translational bottlenecks through open innovation and take European leadership in the development of ATMPs. iPSpine seeks to offer reducing translational bottlenecks through open innovation of novel technologies and ATMPs for the advanced therapy research TERMIS community. IDD will be the showcase. The focus of this symposium will be on regenerative treatment strategies employing iPSC-based and enabling instructive smart biomaterials.
**Symposium Title**
Advanced tissue manufacturing strategies and applications

**Symposium Organisers**
Miguel Castilho, Dept. of Orthopaedics, University Medical Center Utrecht, The Netherlands; and Dept. of Biomedical Engineering, Eindhoven University of Technology, The Netherlands
Email: M.DiasCastilho@umcutrecht.nl

Daniela F. Duarte Campos, Bioprinting Lab, Dept. Biomaterials Research, RWTH Aachen University Hospital, Aachen, Germany
Email: daniela.campos@rwth-aachen.de

**Symposium Summary**
Three-dimensional (3D) printing and biofabrication strategies have been in the spotlight for Regenerative Medicine (RM) due to their potential to engineer tissue substitutes, capable of mimicking lost and damaged tissues. This Symposium will focus on new strategies for biofabrication and novel combinations of these, development of bioinks suitable for biofabrication and successful examples that made their way from the bench to the bedside. Moreover, this Symposium will include research applied to the biofabrication of tissue and organ models as potential platforms for effective drug screening prior to animal trials. We will bring together people from both academia and industry, who are especially interested into advanced tissue manufacturing strategies applied to skeletal, cardiovascular and other biological systems.
Symposium Title
Advances and potential of epithelial stem cells in cell therapy

Symposium Organisers
Ying Yang, Institute for Science and Technology in Medicine, Keele University, Stoke-on-Trent, ST4 7QB, United Kingdom
Email: y.yang@keele.ac.uk

Wei Zuo, School of Medicine, Tongji University, 200092, Shanghai, China
Email: zuow@tongji.edu.cn

Symposium Summary
Ground breaking research has revealed that adult stem cells exist in most tissues, and these stem cells are responsible for the lifelong maintenance of tissue homeostasis through their inexhaustible capacity for self-renewal and differentiation. Their role and capacity in repair and regeneration of damaged tissue or organ are attracting great interests in regenerative medicine. Epithelial stem cells have been discovered in skin, cornea, airways. The quantity, the location and the markers of the epithelial stem cells varies based on the physiological and pathological conditions. However, the underlying correlations are less elucidated. Most importantly, few clinical research on application of epithelial stem cells as a new clinical treatment approach has been undertaken. The aim of this symposium is to discuss the state-of-the-art in epithelial stem cell research including, but not limit to: the new markers of epithelial stem cells; the novel techniques which can enrich or purify epithelial stem cells; the niche which maintain the stemness of epithelial stem cells; the outcome of epithelial stem cell application in clinics
Symposium Title
Advancing regenerative medicine by smart fibre-based scaffold design

Symposium Organisers
Thorsten Steinberg, Division of Oral Biotechnology, Centre for Dental Medicine, University Medical Centre Freiburg, Germany
Email: thorsten.steinberg@uniklinik-freiburg.de

Judith Heikoop, IME Medical Electrospinning, Waalre, The Netherlands
Email: j.heikoop@ime-electrospinning.com

Symposium Summary
Fibre-based scaffolds can be designed to form the basis to engineer living tissue replacement by providing mechanical and structural support and to guide the development of well-organized and functional extracellular matrix. This symposium will discuss novel insights in the requirements of the human body for regeneration and the translation of such knowledge into the design and development of scaffolds with well-defined features such as porosity and fiber diameter to allow regeneration of the natural structures of the extracellular matrix in a variety of tissues.
Symposium Title
Animal models in tissue engineering and regenerative medicine - What you need to know

Symposium Organiser
Iris Ribitsch, Equine Clinic, Veterm, Vetmeduni Vienna, Austria
Email: Iris.ribitsch@vetmeduni.ac.at

Symposium Summary (maximum 250 words)
This workshop will provide an overview of animal models currently available in tissue engineering and regenerative medicine. Advances, limitations, suitability to specific clinical indications and suitable analysis will be provided. This workshop is primarily educational in nature and aspiring to provide guidelines for reproducible and accurate in vivo experiments. Suitable power analysis, ethical considerations and regulatory guidelines will also be discussed.
Symposium Title
Bioadhesives for tissue engineering and regenerative medicine

Symposium Organisers
Sylvia Nürnberger, Department of Orthopedics and Trauma-Surgery, Division of Trauma-Surgery, University of Vienna, Austria
Email: sylvia.nuernberger@meduniwien.ac.at

Anne Marie Power, Martin Ryan Institute/School of Natural Sciences, National University of Ireland Galway (NUI Galway), Ireland
Email: annemaire.power@nuigalway.ie

Symposium Summary
Tissue glues are important surgical tools in reconstructive surgery, helping to attach native and engineered tissues. However, currently available tissue glues are either weak (fibrin glue) or toxic, containing harmful substances such as glutaraldehyde, formaldehyde or cyanoacrylates (e.g. BioGlue®, Histoacryl®). These are either insufficient for stabilization, or they damage cells that are necessary for healing and regeneration of the tissue or organ. This leads to the need to develop new, biocompatible and strong bonding tissue glues. Nature has found multiple solutions to bond permanently or temporarily, even under moist conditions and under water. One of the most intensively studied examples of bioadhesives are the mussel foot proteins of the Mytilus mussel. The bonding-relevant amino acid DOPA which was isolated from Mytilus has already been applied in several ways (as cell and tissue glue, for surface coatings of textiles and food) and tested in preclinical studies. However, the bonding strength is just slightly higher than that of fibrin, so the necessity of finding stronger tissue glues remains a relevant goal. There are many other adhesive-generating organisms, from bacteria, algae and fungi to invertebrate animals and vertebrates. These organisms are of increasing interest to researchers, who recently founded the ENBA network supported by the European COST-Action program (CA-15216). Within this ENBA-associated TERMIS session, we want to discuss to most recent findings on bioadhesives with potential applications in surgeries, tissue engineering and regenerative medicine.
Symposium Title
Bioengineered functional niches for the clinical translation of TERM therapies

Symposium Organisers
Manuela T. Raimondi, Department of Chemistry, Materials and Chemical Engineering “G. Natta”, Politecnico di Milano, Milano, Italy
Email: manuela.raimondi@polimi.it

Riccardo Gottardi, Center for Cellular and Molecular Engineering, Department of Orthopaedic Surgery, Department of Chemical Engineering, and the McGowan Institute for Regenerative Medicine, University of Pittsburgh, United States of America
Email: rig10@pitt.edu

Symposium Summary
This symposium will focus on bioengineering strategies to model complex cell microenvironments to effectively and efficiently translate TERM-based therapies to the clinics, while refining, replacing and reducing animal testing. The approaches discussed will for instance include the use of 3D culture substrates with controlled mechano-topology, surface functionalisation, release of factors and perfused culture, to instruct cell response in vitro and mimic the in vivo conditions. Furthermore, we will explore the use of in vivo bioreactors monitored using transcutaneous two-photon microscopy on miniaturised imaging windows. We will specifically address the technological challenges of cell models that support the clinical translation and commercialisation of TERM therapies. Examples of possible applications are: 1) the mesenchymal stromal cell (MSC) niche, such as 3D substrates nano-engineered via two-photon laser polymerization for the functional maintenance under expansion of human MSC and of induced pluripotent stem cells; 2) the osteochondral niche, mimicked by adjacent tissue layers of bone- and cartilage-like constructs perfused separately in microfluidic systems; 3) the bone marrow vascular niche, e.g., synthetic fibrin substrates comprised of arrays of micro wells with desired fluid-induced shear strains to maintain hematopoietic progenitors such as megakaryocytes, to be used clinically for the production of platelets to treat thrombocytopenia; 4) the myogenic niche, e.g., multifunctional alginate cryogels utilized as synthetic niches to modulate regenerative potential of MSCs and enhance skeletal muscle regeneration; 5) another example is polymeric, chemically defined cellular niches for the support of functional cardiomyocytes derived from human embryonic stem cells in a serum-free fully defined culture system.
Symposium Title
Bioinspired systems for regenerative medicine

Symposium Organisers
Manuel Salmeron-Sanchez, Centre for the Cellular Microenvironment and Division of Biomedical Engineering, University of Glasgow, Scotland, United Kingdom
Email: Manuel.Salmeron-Sanchez@glasgow.ac.uk

Amaia Cipitria, Max Planck Institute of Colloids and Interfaces, Postdam, Germany
Email: Amaia.Cipitria@mpikg.mpg.de

Symposium Summary
The Extracellular Matrix (ECM) is a highly-structured environment that provides cells with physical support and biochemical signals. One of the main aims in regenerative medicine is the development of synthetic ECMs which recapitulate most of the properties of the native one, seeking to promote cell integration and performance of physiological functions in therapeutic strategies. Inspired by nature, we want to focus this symposium on novel strategies which involve the design, properties and biological evaluation of a number of 3D systems aimed at working as self-contained environments that recapitulate key processes in regenerative medicine. Materials involved include porous scaffolds, hydrogels decorated with bioinstructive ligands, minituarised hybrid elements that can be assembled into hierarchical organizations similar to living tissues and, importantly, devices (e.g. advanced systems responsive to external stimuli) which recapitulate most of the characteristics of the ECM. The development of novel bioinspired systems and devices are relevant in TERM, as we need novel concepts to mimic the complexity of nature to be delivered as simple and robust therapeutics in regenerative medicine. The symposium targets a large variety of researchers and clinicians in the field of tissue engineering and regenerative medicine. It is broad enough to be within the remit of bioengineers who work in the design of novel synthetic ECMs (bioinspired materials), stem cell scientists whose main interest is the control differentiation of stem cells using material-based approaches and scientist pursuing translational approached to bioinspired materials, including clinical trials.
Symposium Title
Biomaterials and devices for treatment of diabetes Mellitus

Symposium Organiser
J Carlos Rodriguez-Cabello, UVa, Spain
Email: roca@bioforge.uva.es

Symposium Summary
Type 1 diabetes is a chronic disease in which the insulin-producing islet cells of the pancreas are attacked by the immune system and destroyed. In the last decades, islet cell transplantation has emerged as a promising treatment option for restoring insulin production and effectively normalizing blood glucose levels. However, despite the tremendous potential of this cell-based therapeutic approach, major limitations, such as the scarce availability of donor insulin-producing cells and the gradual loss of islet graft function due to immune rejection, have significantly impacted on its application in the clinical routine. Advances in cell reprogramming and biomaterial technologies have provided key tools to overcome these barriers. This symposium will focus on the most recent developments on novel biomaterial designs and encapsulation methods to enable islets or islet-like cells immunoisolation, and to improve their survival and function after transplantation. It will also detail advances in ancillary technologies to aid the translation of these novel biomaterial designs and encapsulation methods.
Symposium Title
Biomaterials for 3D cancer models

Symposium Organisers
Subhas C. Kundu, I3Bs - Research Institute on Biomaterials, Biodegradables and Biomimetics, Headquarters of the European Institute of Excellence on Tissue Engineering and Regenerative Medicine, University of Minho, AvePark - 4805-017 Barco, Guimaraes, Portugal
Email: kundu@i3bs.uminho.pt

Vitor M. Correlo, I3Bs - Research Institute on Biomaterials, Biodegradables and Biomimetics, Headquarters of the European Institute of Excellence on Tissue Engineering and Regenerative Medicine, University of Minho, AvePark - 4805-017 Barco, Guimaraes, Portugal
Email: vitorcorrelo@i3bs.uminho.pt

Symposium Summary
Researchers on tissue engineering, cell and molecular biology, drug screening, delivery and development, will get an opportunity to know about the current methodologies and technologies for the development and uses of a large plethora of biomaterial-based matrices, mainly for 3D cellular and cancer disease models. The biomaterial-based scaffolds will be explored to develop highly realistic 3D in vitro tumor models for anticancer therapies screening, and models for disease microenvironment dynamics. These advanced technologies will provide a means to engineer in vitro tumor microenvironment and cell migration to study and manipulate cancer and other diseases. Advances being made with 3D bioprinting using bio-ink, micro-patterning, microfluidic devices for the study of cell migration (e.g. tumor cell invasion, intravasation, and extravasation) tissue growth including other properties of biomaterial matrices like detection and imaging materials are also within the scope. Therefore, organizing a symposium discussing the state-of-art of emerging technologies to deeper investigate cancer disease and innovative treatments using in vitro models are the demand of the current edge and of practical uses for cancer therapies. Graduate and postgraduate students, and experienced researchers in biotechnology, biomedical engineering working in the fields of natural or synthetic biomaterials, drug deliveries, emerging technologies, tissue engineering and regenerative medicine applied to cancer diseases and/or development, comprise the audience of this symposium. In particular, those working with biomaterials, natural and micro-nano composite biomaterials, 3D in vitro microenvironment modulations, cell-based bio-inks, 3D tumor disease modeling, nanoparticle-based delivery vehicle, micro-patterning, and drug screening using latest emerging technologies like microfluidics, bio-printing, tumor lab-on-a chip, spheroids, and micro-tissues.
Symposium Title
Biophysical stimuli for controlling in situ cell function

Symposium Organisers
Bernd Rolauffs, G.E.R.N. Tissue Replacement, Regeneration & Neogenesis, Department of Orthopedics and Trauma Surgery, Medical Center Albert-Ludwigs-University Freiburg, Germany
Email: bernd.rolauffs@uniklinik-freiburg.de

Martin Stoddart, AO Foundation, AO Research Institute Davos, Davos, Switzerland
Email: martin.stoddart@aofoundation.org

Symposium Summary
Both stem cells and primary cells are highly relevant in the context of current clinical use as well as future cell therapies, as they hold potential for improving disease outcomes. Thus, optimizing methods for controlling cell fate in the patient are of considerable importance. Strategies for applying defined biophysical stimuli and/or combining such stimuli in order to achieve the desired in situ cell control are especially interesting, as this non-invasive approach may result in cell-instructive medicinal products and not ATMPs, which are more difficult to license. Thus, this symposium focuses on defined biophysical stimuli such as the application of mechanical forces, material stiffness, and micro- and/or nanostructures for controlling cell functions such as morphology, phenotype and expression profiles.
Symposium Title
Biophysical therapies in regenerative medicine

Symposium Organisers
Paul Slezak, Ludwig Boltzmann Institute for Experimental and Clinical Traumatology, Austrian Cluster for Tissue Regeneration. Vienna, Austria
Email: paul.slezak@trauma.lbg.ac.at

Giancarlo Forte, Center for Translational Medicine, St. Anne’s University Hospital in Brno, Czech Republic
Email: giancarlo.forte@fnusa.cz

Symposium Summary
Wounds and non-healing fractures impose a significant and often underappreciated burden to the individual, the healthcare system and the society as a whole. Additional treatment beyond standard care may be required to complete healing. In response to this clinical need, advanced technologies are being developed to improve tissue regeneration. These treatments may involve application of mechanical, light and electrical energy to the wounded tissue. Such biophysical-tissue interactions have already been shown to re-stimulate the natural healing pathways. Detailed knowledge of the pathways stimulated by these treatment modalities is growing. Researchers have attempted to study the biologic effects of these fields and sought to identify any physical properties or specific characteristics of biological fields upon which to determine a mechanism of actions. Although increasing evidence supports the clinical usage of these therapies, routine treatment protocols have not yet been established. Importantly, variations of equipment and technique may introduce variations at the wound surface that influence healing. Such developments would help define the wound system, establish primary biophysical-tissue interactions, and develop optimized protocols for specific wound healing needs leading towards broader adoption into clinical practice for improved care of chronic wounds. This symposium aims to elucidate applications of biophysical applications in regenerative medicine approaches. Basic research as well as clinical applications will be discussed.
Symposium Title
Bone and cartilage engineering: From polymers, cells and 3D printing towards clinical translation

Symposium Organiser
Sandra Van Vlierberghe, Polymer Chemistry & Biomaterials Group, Centre of Macromolecular Chemistry, Department of Organic and Macromolecular Chemistry, Ghent University, Belgium
Email: Sandra.VanVlierberghe@UGent.be

Symposium Summary
The symposium will cover all aspects associated with bone and cartilage engineering. Both natural and synthetic polymers as well as derivatives thereof will be addressed along with a variety of chemistries thereby creating the targeted structural and functional properties. This could enable the production of devices for hard tissue regeneration. Furthermore, rapid prototyping (laser-, nozzle- and printer-based) techniques will be highlighted given their ability to develop patient-specific implants using a CAD-CAM approach. Current trends will be highlighted together with solutions to tackle existing processing limitations. Strategies to control the mechanical properties of scaffolds will be highlighted as well. In addition, approaches to tune the biodegradability will be discussed while ample attention will also be paid to scaffold functionalization as well as characterization prior to and after processing. Finally, the in vitro biological assessment and in vivo response of the processed polymers will be discussed. In addition to material-related aspects, ample attention will also be paid to the cell source applied. Indeed, besides cell-associated therapies based on (fibro)chondrocytes, also stem cell approaches for bone and cartilage engineering will be addressed, both from a research as from a clinical perspective. Finally, regulatory aspects, translational approaches and the establishment of pre-clinical trials in the hard tissue engineering field will also be highly welcomed.
**Symposium Title**  
Cartilage-inspired matrices for musculoskeletal tissue regeneration

**Symposium Organisers**  
Debby Gawlitta, Oral and Maxillofacial Surgery and Special Dental Care, University Medical Center Utrecht, Utrecht, The Netherlands  
Email: d.gawlitta@umcutrecht.nl

Lizette Utomo, Oral and Maxillofacial Surgery and Special Dental Care, University Medical Center Utrecht, Utrecht, The Netherlands  
Email: l.utomo-2@umcutrecht.nl

**Symposium Summary**  
Generation or regeneration of musculoskeletal tissues (e.g. articular cartilage, bone, tendon, and menisci) dominate the tissue engineering market. Various approaches to create a 3D mimic of the target tissue have been proposed since the concept of tissue engineering was introduced over twenty-five years ago. The use of natural materials, synthetic materials, or a combination of both for engineering musculoskeletal tissues, is popular due to the availability, customizability, and support of cell differentiation. To some extent, they meet the demanding quality requirements of the tissues; however, improvements are desirable. This symposium will focus on approaches for the generation and application of cartilage-derived matrices for regeneration of musculoskeletal tissues. For example, cartilage and bone are tissues that are closely linked to each other, both on an anatomical level *in situ* and developmental level. A well-known natural-occurring process that allows development of bone from a cartilage template is endochondral bone formation. To this end, tissue engineering approaches (e.g. decellularized-, devitalized-, or collagen/glycosaminoglycan scaffolds) have emerged that have taken inspiration from the native composition of the tissues, or natural-occurring developmental processes, topics that will be addressed during this symposium.
Symposium Title
Controlling stem cell pathways through materials

Symposium Organisers
Olga Tsigkou, School of Materials, University of Manchester, Manchester M1 2PG, United Kingdom
Email: olga.tsigkou@manchester.ac.uk

Julian Jones, Department of Materials, Imperial College London, South Kensington Campus, London, United Kingdom
Email: julian.r.jones@imperial.ac.uk

Symposium Summary
Bone marrow and adipose stem cells have emerged as prime candidates for regenerative medicine strategies, particularly for in situ procedures, e.g. microfracture, where bone marrow stem cells produce cartilage. Biomaterials are now known to be able to guide stem cell differentiation pathways through their surface chemistry, topography, stiffness or by releasing active ions during biodegradation. This symposium explores how materials can guide stem cell differentiation down tissue-specific pathways, using examples that are already in clinical use. It will also explore the translation processes for new materials that have such properties, now that regulatory procedures are becoming more stringent.
**Symposium Title**
Design of dynamic-instructive cell microenvironments for enhanced tissue engineering applications

**Symposium Organisers**
João F. Mano, Department of Chemistry, CICECO – Aveiro Institute of Materials, University of Aveiro, Portugal
E-mail: j mano@ua.pt

Clara R. Correia, Department of Chemistry, CICECO – Aveiro Institute of Materials, University of Aveiro, Portugal
E-mail: claracorreia@ua.pt

**Symposium Summary**
The development of a new generation of materials and systems for Tissue Engineering and Regenerative Medicine (TERM) should include spatio-temporal control of signals (e.g. mechanical, biochemical, or physicochemical stimuli) that will be recognized by cells at different time points to accomplish specific therapeutic functions. Novel materials and systems are being developed to recapitulate the dynamic properties of the extracellular matrix (ECM) that should result in the engineering of microenvironments that are bioinspired to trigger regeneration processes. Micro/nano-technologies, combined with chemical strategies could be used to assemble proteins, cells, soluble factors and supporting biomaterials into multi-scale structures with potential to have clinical impact in tissue repair. Particular emphasis will be given to approaches that consider regulatory hurdles and pathways towards commercialization.
Symposium Title
Designing pro-regeneration biomaterials-based implants that overcome the regulatory challenges

Symposium Organisers
May Griffith, Department of Ophthalmology & Institute of Biomedical Engineering, University of Montreal, Canada
Email: May.Griffith@umontreal.ca

Jöns Hilborn, Department of Chemistry - Ångström Laboratory, Upsala University, Sweden
Email: jons.hilborn@kemi.uu.se

Symposium Summary
Novel biomaterials-based devices and scaffold for cell-therapies with blockbuster effects, are constantly published high impact journals. However, they are not being translated into clinical application. A major hurdle is the regulatory requirements of demonstrating safety of the medical devices or scaffolds developed as Advanced Therapy Medicinal Products (ATMP). Demonstrating safety of novel materials requires considerable time and expenditure due to the need for extensive toxicology and biocompatibility testing in research organizations certified to adhere to Good Laboratory Practice guidelines. Researchers find themselves choosing between the practicality of used pre-regulatory approved materials that would allow rapid clinical translation or designing novel materials that may never reach the clinic. Is this a necessary choice? Can we design novel, innovative implants using approved biomaterials? This symposium will discuss the challenges faced by scientists working in the translational regenerative medicine arena. Experts who have managed the transitioning of their research outcomes from the laboratory into the realm of clinical testing will share their experience and provide tips for complying with regulatory requirements while continuing to innovate and develop new therapies.

**Symposium Title**
Engineered materials for peripheral nerve repair and regeneration

**Symposium Organiser**
Srinivas Madduri, Department of Biomedical Engineering, University of Basel, Switzerland
Email: srinivas.madduri@unibas.ch

**Symposium Summary**
Repair and regeneration of injured peripheral nerves is critical and challenging. More than one million patients are reported around the world annually, and most of the patients are affected with life-long disabilities due to lack of effective therapeutic measures. Currently available treatment options are associated with many limitations and clinical outcomes are sub-optimal. Thus, there is a great need for clinical and industrial development of advanced biomaterials based nerve conduits for improving the quality of patient’s life. This symposium will discuss the biologically functional nerve conduits and the critical aspects of their clinical translation and commercialization. Multidisciplinary professionals covering the areas of bioengineering, Schwann cells/stem cell therapy, nerve conduit scaffolds, human nerve injuries and regulatory processes are invited for presenting the recent advancements and future directions.
Symposium Title
Engineering advanced biomaterials-based therapeutic platforms for joint repair

Symposium Organisers
Arlyng Gonzalez-Vazquez, Tissue Engineering Research Group (TERG), Department of Anatomy, Royal College of Surgeons in Ireland, Dublin, Ireland
Email: agonzalez@rcsi.ie

Caroline Curtin, Tissue Engineering Research Group (TERG), Department of Anatomy, Royal College of Surgeons in Ireland, Dublin, Ireland
Email: carolinecurtin@rcsi.ie

Symposium Summary
Adult articular cartilage has a limited capacity for repair and when damaged or injured, experiences a loss of function, which leads to joint degeneration and ultimately may lead to osteoarthritis. Biomaterials-based treatments have had limited success due to the complex zonal structure of the articular joint, problems with biomaterial retention at the joint surface and achieving integration with the host tissue while also maintaining the appropriate load bearing capacity. Stem cell therapies have also failed to live up to significant hype for a number of reasons including the challenges associated with achieving formation of stable hyaline cartilage, which does not undergo hypertrophy. Highlighting the need for engineering advanced therapies for joint repair, this symposium will focus on strategies to overcome the problems with traditional biomaterial approaches and will incorporate recent advances in the area of advanced manufacturing and 3D bioprinting to address the complexity of the articular joint. New approaches for scaffold-mediated therapeutic delivery – including stem cells, growth factor delivery and gene therapy – that might be used to direct cells to regenerate large areas of joint damage will also be considered.
Symposium Title
Engineering immunity: From regenerative immunology to immunotherapy

Symposium Organisers
Kaitlyn Sadtler, Massachusetts Institute of Technology, Cambridge, MA, United States of America
Email: Email, ksadtle3@jhmi.edu

Jennifer H. Elisseeff, Translational Tissue Engineering Center, Wilmer Eye Institute and Department of Biomedical Engineering. Bloomberg-Kimmel Institute for Cancer Immunotherapy, Johns Hopkins University School of Medicine, Baltimore, MD, United States of America
Email: jhe@jhu.edu

Symposium Summary
The immune response is tightly regulated by a myriad of complex networks of cells, biophysical cues and biochemical molecules (e.g. cytokines and antibodies) that allow the body to execute a specific response in order to maintain homeostatic equilibrium. If this balance is not adequately maintained or being disrupted, dysregulated immune responses persist leading to many inflammation-centered disease processes; including age-related degenerative diseases, autoimmune disorders and cancer. Synthetic biomaterials have emerged as promising tools that can be engineered to interrogate the immune system by precisely modulating the spatiotemporal dynamics of the innate or adaptive immunity in order to promote tissue repair or to eliminate cancer. In view of the rapid advancements in the now exploding field of immunoengineering, this symposium is timely! The symposium will broadly cover areas of investigation that have deep implications to numerous aspects of human health (regenerative immunology and cancer immunotherapy). If accepted, this interdisciplinary symposium should be of interest to a diverse group of researchers including cell biologist, clinical immunologists, bioengineers and materials scientists.
Symposium Title
From innovative hydrogel chemistry to musculoskeletal regeneration approaches

Symposium Organisers
Pierre WEISS, INSERM UMRS 1229, Regenerative Medicine and Skeleton (RMeS), Nantes University, School of Dental Surgery, Nantes, France
Email: pierre.weiss@univ-nantes.fr

Vianney DELPLACE, Chemical Engineering & Applied Chemistry, Donnelly Centre, University of Toronto, Canada
Email: vianney.delplace@gmail.com

Symposium Summary
The field of hydrogels for Tissue Engineering and Regenerative Medicine is a prolific area of research with applications for most bodily tissues. Over the last decade, scientists have incorporated biological (growth factors, cytokines) and biophysical (substrate topography, material stiffness, degradable sequences) cues as a mean to better understand cell/scaffold interactions as well as enhancing therapeutic outcomes. This symposium aims to address these new developments and to highlight both basic science studies and recent translational applications. Invited presentations will showcase recent advances, covering both chemical and biological aspects of the design of functional hydrogels, able to recapitulate some of the fundamental cues of native environments to drive the local tissue regeneration. More specifically, invited talks will focus on (i) the design and characterization of novel polymer network chemistries for imaging constructs, and (ii) recent regenerative applications of hydrogels on musculoskeletal tissues, and the importance of considering the target microenvironment in their design and validation. This symposium will target a diverse audience of students and young scientists, experts from both academia and industry, working in the field of biomedical hydrogels. It will be organized under the auspices of the Society for Biohydrogels, which aims to promote scientific exchanges on hydrogels developed in the fields of life and pharmaceutical sciences, health, and regenerative medicine.
Symposium Title
From surface to cell to bone: deciphering essential components to induce bone formation

Symposium Organisers
Sandra Hofmann, Dept. of Biomedical Engineering, Eindhoven University of Technology, Eindhoven, The Netherlands
Email: s.hofmann.boss@tue.nl

Jeroen JJP van den Beucken, Dept. of Regenerative Biomaterials, Radboudumc, Nijmegen, The Netherlands
Email: jeroen.vandenbeucken@radboudumc.nl

Symposium Summary
Bone regeneration requires knowledge of the interactions between bone cells and bone substitute materials. From a bone remodelling perspective, both bone forming osteoblasts and bone resorbing osteoclasts act in concert to attain a state, in which the net result is ‘increased bone formation’, ‘homeostasis’, or ‘increased bone resorption’. As such, it is instrumental for bone regenerative therapies to steer the result of osteoblast-osteoclast interactions toward ‘increased bone formation’. Emerging evidence demonstrates that material surface properties play a decisive role in osteoinduction, and that particularly osteoclasts initiate the physiological process of bone formation. Additionally, advanced cell culture techniques involving both 2D and 3D osteoblast/osteoclast cocultures have enabled the detailed analysis of cell characteristics and factors involved in this intriguing interaction toward elucidation of the mechanistic principles of osteoinduction. This symposium will highlight the latest insights into material surface properties, cell-based bone regeneration, and cell (co)culture models to advance the understanding of cell-material and cell-cell interactions that underlie osteoinduction. Joining forces on material development, immunology, cell biology, and clinical translation will accelerate the availability of powerful bone regenerative therapies for patient treatment.
Symposium Title
Functional bone tissue engineering using 3D printed biomimetic scaffolds

Symposium Organisers
Xuebin Yang, Department of Oral Biology, University of Leeds, LS97TF, United Kingdom
Email: X.B.Yang@leeds.ac.uk

Pedro Morouço, Biofabrication Research Group, Polytechnic Institute of Leiria, Portugal
Email: pedro.morouco@ipleiria.pt

Symposium Summary
The development of clinical relevant biomimetic scaffolds is still one of the most challenge basic elements for functional tissue engineering. Ideal scaffolds for bone tissue engineering should not only support stem cells/osteoprogenitors growths and form new bone tissues, but also allow the bone remodelling to occur at the right time and right way. Bioprinting has been used to develop 3D scaffolds with different architectures and many advantages over the conventional methodologies. However, there are still limitations with this technology, which need to be overcame before meeting the real clinical requirements. This symposium will discuss about 1) the fundamental procedure of bone development, fracture healing and bone remodelling, which aims to provide evidence for guiding the design of next generation of biomaterial scaffolds; 2) current advance in bone tissue engineering in vitro and in vivo; 3) the latest development in bioprinting technology and how to use this to design and fabricate the ‘customer oriented’ biomaterial scaffolds for translational research on bone augmentation.
Symposium Title
Functional properties of dental pulp stem cells for tissue regeneration

Symposium Organisers
Catherine Chaussain, Lab Orofacial Pathologies, Imaging and Biotherapies, University of Paris, France
Email: catherine.chaussain@parisdescartes.fr

Ivo Lambrichts; Hasselt University, BIOMED, Belgium
Email: ivo.lambrichts@uhasselt.be

Symposium Summary
The grafting of a tissue-engineered construct seeded with adult mesenchymal stem cells (MSCs) into injured and ischemic tissues has emerged in the past decade as a potential therapeutic option for tissue repair and regeneration. The success of such an approach is directly conditioned by the establishment of a fully functional vascular network within the grafted tissue construct to allow its survival. Identifying stem or progenitor cell populations able to participate in tissue regeneration and promote angiogenesis is therefore essential for developing such novel tissue engineering strategies. This symposium will focus on dental pulp mesenchymal stem cells (DPSCs) that have been introduced as a potential source for tissue engineering because of their easy access and less invasive approach for harvest as well as their extended potential for proliferation, differentiation (trilineage capacity) and their paracrine properties. As the dental pulp is mainly composed of neural crest-derived mesoderm (ectomesenchym), research on DPSCs also reports their plasticity to transdifferentiate to neural-like cells and indicates their healing potential in treating disorders of the nervous system such as stroke.
**Symposium Title**  
Functionalisation at nanoscale to enhance specific biological activities

**Symposium Organisers**  
Piergiorgio Gentile, School of Engineering, Newcastle University, Newcastle Upon Tyne, United Kingdom  
Email: Piergiorgio.Gentile@newcastle.ac.uk  

Irene Carmagnola, Department of Mechanical and Aerospace Engineering, Politecnico di Torino, Torino, Italy  
Email: irene.carmagnola@polito.it

**Symposium Summary**  
The reproduction of the complexity of the cellular environment at nanoscale, from the ECM structure to the presence of cytokines and intracellular signaling, is a fundamental activity of manufacturing biologically functional constructs for Tissue Engineering and Regenerative Medicine. In this context nanotechnologies have emerged as potential and attractive manufacturing tool to allow the mimicking of the nanoscale detail of the cell's environment through controlling the surface chemistry and topography of materials, generating 3D cellular scaffolds and regulating cell-cell interactions. Controlling and manipulating biomaterials at the nanoscale through nanotechnology approaches has enabled to the design and manufacture of suitable cellular environments, bioengineering of functional tissues, and the development of effective drug delivery systems. The recent developments in nanotechnologies have focused on the: (1) fabrication of 3D nanoscale geometric features, and (2) modification of biomaterial surfaces via i.e. self-assembly or peptide grafting in order to engineer functional tissues. By bringing together different experts in Tissue Engineering and Regenerative Medicine, the symposium provides an overview of the most recent achievements in the context of nanoscale tailoring of biomaterials to direct cell fate and offers an occasion of networking to drive further development in the field.
Symposium Title
Functionalisation of materials for tissue engineering & regenerative medicine: Concept, commercialisation & clinical use

Symposium Organiser
Katja Schenke-Layland, Director of The Natural and Medical Sciences Institute (NMI) at the University of Tübingen in Reutlingen, Germany
Email: kschenkelayland@me.com

Symposium Summary
Many established biomaterials used today in medicine and surgery were originally selected on the basis of their so-called “bioinert” behaviour following implantation. While the focus of much research in recent decades has therefore been on the discovery and refinement of so-called bioactive materials, parallel advances in materials processing (including manufacturing technologies) and extracellular matrix biology have also made it possible to modify previously bioinert devices to introduce tailored biofunctionality. This field is maturing rapidly, with a growing body of both publications and intellectual property, and multi-functional devices are starting to reach the market and clinic.
Symposium Title
Green tissue engineering: How green tissue engineering can improve biological functions and save the environment

Symposium Organisers
Thomas J. Webster, Chemical Engineering Department, Northeastern University, Boston, MA, United States of America
Email: th.webster@neu.edu

Jose Miguel Garcia-Martin, Spanish Research Council (CSIC), Department of Fabrication and Characterization of Nanostructures at the Institute of Micro and Nanotechnology (IMN-CNM, CSIC), Madrid, Spain
Email: josemiguel.garcia.martin@csic.es

Symposium Summary
Interest in tissue engineering has exploded due to the combination of cells and engineered materials which under suitable physicochemical and biochemical factors can regrow biological tissue. However, these newly synthesized materials usually have drawbacks before, during and after biological implantation. For example, during synthesis, environmental problems exist as related to the use or production of toxic by-products or expensive procedures that rely on extensive fossil fuels. During tissue growth, variable levels of cytotoxicity may be apparent. As a potential solution, green tissue engineering uses environmentally-friendly, cost-effective and biocompatible methods for the generation of materials that do not harm the environment but can be applied to tissue engineering. For example, metallic biomaterials have been synthesized by microorganisms (such as bacteria, fungi and human cells). Dietary compounds (such as tea or coffee extracts), plants or hydrothermal approaches with less energy have also been demonstrated to show greater biomedical properties (such as antibacterial, anticancer, tissue growth, and cytocompatibility properties) than traditional non-green chemistry tissue engineering materials. This symposium will emphasize several green chemistry synthetic approaches, characterization methods and medical applications of green tissue engineering materials, constituting a new field termed green tissue engineering.
**Symposium Title**  
Growth factor engineering for regenerative medicine

**Symposium Organisers**  
Yoshihiro Ito, Nano Medical Engineering Laboratory, RIKEN Cluster for Pioneering Research, Japan  
Email: y-ito@riken.jp

Guoping Chen, Research Center for Functional Materials, National Institute of Materials Science, Japan  
Email: Guoping.CHEN@nims.go.jp

**Symposium Summary**  
To construct organs or tissues, scientific research and technological innovation are directed towards reconstruction of more functional in vitro microenvironments including matrix and soluble signalling proteins. To this end, numerous technologies, including three-dimensional biomaterials, biophysical cues (e.g. topography, rigidity, localized density, mechanical loading) and biological signals (e.g. growth factor supplementation) are under intense investigation as means to control permanently differentiated cell phenotype and to direct stem cells towards specific lineage. Chemical immobilization strategies of growth factor delivery allow for localized and strong interactions between growth factors and the resident cells. Challenges in this approach include finding the correct balance between the factor dose and physical and chemical properties of the scaffold, which can regulate cell behaviours. Covalent bonding of growth factors to material carriers can provide more prolonged release than that achieved by physical immobilization. There are other potential advantages in presenting growth factors as matrix-tethered molecules for applications in tissue engineering, as well. The factors remain competent to bind and activate the growth factor receptors, but are more slowly degraded and internalized. Factors can be conjugated to the polymers via functional groups, which are incorporated by copolymerization or chemical or physical treatment. This symposium will discuss these key growth factor engineering and elucidate how the newly developed knowledge will enable clinical translation in the years to come.
Symposium Title
Human pluripotent stem cells for skeletal tissue engineering and regenerative medicine

Symposium Organisers
Darja Marolt Presen, Ludwig Boltzmann Institute for Experimental and Clinical Traumatology, Austrian Cluster for Tissue Regeneration, Vienna, Austria
Email: darja.marolt@trauma.lbg.ac.at

Susan J Kimber, University of Manchester, Manchester, United Kingdom
Email: sue.kimber@manchester.ac.uk

Symposium Summary
Different types of human stem cells have been used for skeletal tissue engineering and regenerative medicine (TERM), each presenting a unique set of advantages and limitations with regard to the desired research and therapeutic goals. This symposium will focus on the use of human pluripotent stem cells (PSCs), which represent a highly promising research and therapeutic cell source in skeletal TERM, due to their unlimited self-renewal and ability for differentiation into mesodermal derivatives as well as other lineages. The symposium will address scientific challenges associated with PSCs, including reproducible and efficient expansion, differentiation and engineering of stable, mature organoids/tissue structures from hPSCs, as well as safety, costs and scale-up considerations on the path of clinical translation. Various applications in skeletal TERM are invited for the presentations and discussion, including derivation and in vitro/in vivo functional evaluations of hPSC-derived skeletal progenitors, tissues and soluble factors; PSC-based tissue engineering in combination with scaffolds, bioprinting and bioreactors; disease modelling and drug discovery. Examples from cartilage, bone and other skeletal tissues will be discussed, to elucidate the current state and future directions in this exciting field.
Symposium Title
Hybrid bioprinting: Recent progress and perspectives

Symposium Organisers
Nicanor I. Moldovan, Department of Biomedical Engineering, Indiana University, Purdue University, Indianapolis, United States of America
Email: nimoldov@iupui.edu

Michael Raghunath, Department of Life Sciences and Facility Management, Zurich University of Applied Sciences (ZHAW), Director, Competence Centre Tissue Engineering for Drug Development (TEDD), Wädenswil, Switzerland
E-mail: ragh@zhaw.ch

Symposium Summary
The overarching principle of Bioprinting is the placing of cells in a 3D pattern to generate a cohesive tissue microarchitecture that emulates its *in vivo* characteristics. To achieve this goal, the cells are usually delivered in a printing medium called ‘bioink’, a hydrogel that contains them during the printing process and ensures shape fidelity of the printed structure. However, a ‘scaffold-free’ version of bioprinting, where only cells are used, and the needed matrix is formed by the cells themselves, recently entered a phase of accelerated development and successful applications. Scaffold-free approaches may still benefit from secondary incorporation of scaffolding materials, thus expanding their versatility. Reversibly, the bioink-based bioprinting could also be improved by adopting some practices of scaffold-free biofabrication, such as the incorporation of pre-formed cell clusters. Collectively, we anticipate that the combination of these complementary methods in a ‘hybrid’ approach, rather than their development in separate technological niches, will largely increase their efficiency and applicability. In this symposium we will review the progress made so far in this area of tissue engineering, and discuss new directions for expansion, improvement and translational applications.
Symposium Title
Immunomodulation in regenerative medicine by functional scaffolds and immune cell programming

Symposium Organiser
Julia Kzhyshkowska, Department of Innate Immunity and Tolerance, Institute of Transfusion Medicine and Immunology, Medical Faculty Mannheim, University of Heidelberg, Germany
Email: julia.kzhyshkowska@medma.uni-heidelberg.de

Alina Vladescu, Department for Advanced Surface Processing and Analysis by Vacuum Technologies, National Institute for Research and Development for Optoelectronics (INOE 2000), Romania
Email: alinava@inoe.ro

Symposium Summary
One of the persistent problems around tissue engineering scaffolds is the failure of macrophages to resolve the inflammation. During the initial phase, pro-inflammatory macrophages induce acute reactions to trauma and foreign materials, whereas tolerogenic anti-inflammatory macrophages control resolution of inflammation and induce the subsequent healing stage. However, implanted materials can induce a mixed pro/anti-inflammatory phenotype, supporting chronic inflammatory reactions accompanied by microbial contamination and resulting in poor integration and even failure. Currently immunomodulatory biomaterials for improved interaction with host tissue or surfaces that release anti-inflammatory drugs/bioactive agents are under development as tissue engineering scaffold components to improve clinical outcomes. However, no definitive, long-term solution to avoid adverse immune responses to the implanted materials is available to date. The immunomodulatory properties of currently available scaffolds need to be improved to develop personalized therapeutic solutions. Our symposia will be focused on the advanced approaches aimed to prevent the implantable material-associated infections and to inhibit the development of the local chronic inflammation. The symposia will be focused on two major approaches: 1) surface functionalization of tissue engineering scaffolds by the bioactive and antibacterial coatings, and 2) long-term fixation of anti-inflammatory macrophage phenotypes to improve scaffold integration. The most recent advances in the fields of materials science, biotechnology, immunology and cell therapy will have a significant impact on the international scientific community by intensifying the interdisciplinary research in regenerative medicine and will open new horizons for the career development of young investigators and will demonstrate the close cooperation of academia and industry. The knowledge transfer will have a high socio-economic impact by providing the industry with the innovative solutions for personalised regenerative medicine that will improve life quality of the patients.
Symposium Title
Injectable scaffolds in tissue engineering

Symposium Organiser
Wenxin Wang, Charles Institute of Dermatology, School of Medicine, University College Dublin, Dublin, Ireland
Email: wenxin.wang@ucd.ie

Jing Lyu, Charles Institute of Dermatology, School of Medicine, University College Dublin, Dublin, Ireland
Email: jing.lyu@ucdconnect.ie

Symposium Summary
Injectable scaffolds have attracted broad attention in tissue engineering and regenerative medicine because of their promising advantages over performed scaffolds, including ease of application, confined delivery for a site-specific action and improved patient compliance. In addition, injectable scaffolds mixing with cells form a uniformly distributed cell/scaffold tissue system in vivo, which provide a rich and complex environment of signals to promote tissue regenerate. However, many challenges in the design and development of injectable scaffold-cell system still remain: optimisation of the kinetics of solidification process in-situ; development of injectable scaffold that can withstand the mechanical stresses while maintaining an environment conducive to tissue growth; optimisation of creation of required pore size and formation of inter-connectivity of pores within the solidified scaffold; protection of cell viability during preparation of scaffold and delivery; controlled release of growth factors; understanding of cell-material interaction, “cell-adhesion” and biocompatibility; rate of biodegradation and cytotoxicity; phenotype tissue formation. Thus, a symposium based in this area would fit well with the key theme of the conference. The symposium is aimed at bringing together all aspects of the field, from synthetic chemists interested in developing suitable materials to applied scientists, engineers and clinicians that are interested in the applications of injective scaffolds. This symposium will cover following aspects of the state-of-the-art studies and developments of injectable scaffolds: Design and synthesis of suitable biomaterials for injectable scaffolds including hydrogels and stimuli materials; Functionalization and degradation mechanism studies of polymers for injectable scaffolds; Application and evaluations of polymers for injectable scaffolds.
Symposium Title
Interdisciplinary strategies to regulate cartilage phenotype

Symposium Organisers
Roberto Narcisi, Department of Orthopaedics, Erasmus MC - University Medical Center, Rotterdam, The Netherlands
Email: r.narcisi@erasmusmc.nl

Solvig Diederichs, Research Center for Experimental Orthopaedics, University Hospital Heidelberg, Germany
Email: solvig.diederichs@med.uni-heidelberg.de

Symposium Summary
Hundreds of millions of people worldwide are suffering from cartilage pathologies. Efficient generation of articular cartilage, however, is limited to embryonic development stages. In adulthood, when mature cartilage is damaged (e.g. traumatic events, cancer, congenital disorders) it shows a very limited self-repair capacity and clinical intervention is required, with a huge economic impact for the society. The current options available mainly rely on autologous chondrocyte implantation, a procedure that requires a 2-step surgery, depends on cell availability and most importantly often leads to poor quality cartilage formation. This symposium aims to show and discuss different basic molecular insights and innovative approaches that can instruct progenitor cells to efficiently generate and maintain stable cartilage. Among others, this symposium will provide an overview of the basic molecular mechanisms involved in cartilage generation and maintenance starting from a better understanding of cartilage development, and show some innovative examples of how this basic scientific knowledge can be used for regulating cartilage phenotype for tissue engineering applications, also using stem cells from various origin.
**Symposium Title**  
Is bioprinting really improving our ability to engineer and regenerate musculoskeletal tissues?

**Symposium Organiser**  
Daniel Kelly, Trinity Centre for Bioengineering, School of Engineering, Trinity College Dublin, Ireland  
Email: kellyd9@tcd.ie

**Symposium Summary**  
In recent years there has been significant hype around the use of bioprinting to engineer complex tissues and organs. To date the field of bioprinting has focused predominately on the development of printing hardware and new classes of bioinks to print cells and/or biomolecules, but there have been relatively few examples of bioprinting enabling the engineering of tissues mimicking the complexity of their native counterparts, or of bioprinted implants facilitating superior regeneration over current gold standard treatments. Using articular cartilage as an example, this symposium will first examine how this complex tissue develops and functions, with a view to defining what we need to achieve in cartilage tissue engineering and regeneration. This symposium will then explore (1) developments in bioprinting that have enabled the engineering of musculoskeletal tissues that could not be achieved using traditional tissue engineering strategies, and (2) examples where bioprinting has been shown to facilitate musculoskeletal regeneration in pre-clinical models. This symposium will also look at examples where promising bioprinting strategies have failed to provide improvements over the current state-of-the-art.
Symposium Title
ISBF-TERMIS Joint Young Scientist Chapters. Biofabrication-based strategies for regenerative medicine: towards a new tissue engineering age

Symposium Organisers
Riccardo Levato, Regenerative Medicine Center and Department of Orthopedics, University Medical Center Utrecht (UMCU), The Netherlands
Email: r.levato-2@umcutrecht.nl

Filippo Cipriani, Technical Protein Nanobiotechnology (TPNBT S.L.) Valladolid, Spain
Email: fcipriani@tpnbt.com

Symposium Summary
Biofabrication is becoming a fundamental discipline in Tissue Engineering and Regenerative Medicine (TERM) as key-enabling technology to generate highly advanced 3D engineered constructs that better recapitulate the complexity of native tissues. As such, the convergence of Biofabrication, via bioprinting and bioassembly, and TERM is currently expediting translation of engineered tissues towards the industry, i.e. as platforms for drug screening and organs-on-chips, and tackle some of the key challenges towards clinical translation (i.e. vascularization). The contribution of early stage researchers will be essential for advancing these promising fields. At the same time, the growing importance of Biofabrication is opening new career opportunities for young scientists in the near future. The scope of this symposium is to promote the collaboration and exchange of ideas between researchers and young scientists in the fields of Tissue Engineering and Biofabrication.
Symposium Title
Kidney in focus: improving the replacement therapies and regenerative strategies in kidney disease

Symposium Organisers
Rosalinde Masereeuw, Division of Pharmacology, Utrecht Institute for Pharmaceutical Sciences, Utrecht University, The Netherlands
Email: r.masereeuw@uu.nl

Dimitrios Stamatialis, (Bio)artificial organs, Department of Biomaterials Science and Technology, Faculty of Science and Technology, TechMed Institute, University of Twente, The Netherlands
Email: d.stamatialis@utwente.nl

Symposium Summary
Worldwide, the chronic shortage of kidney donors has created an urgent need for tissue-engineered alternatives. A number of tissue engineering strategies combine three-dimensional (3D) culture systems with developmental biology principles to generate de novo kidney tissue. These approaches start with embryonic kidney fragments or kidney progenitor cells that are induced stepwise to develop into 3D kidney tissue. Other strategies use scaffolds obtained from human or animal kidneys through decellularization as a template for reconstructing a kidney graft, which is then seeded with stem or progenitor cells or living membranes capable of active transport of uremic toxins. Although these approaches have provided very promising results, many challenges must be overcome before engineered kidneys become clinically useful, including size, sufficient vascularization, immunological issues, and proper connection to the host vascular and draining system. In parallel, the use of advanced kidney-on-a-chip as disease modelling platforms could bring further insight in understanding the mechanism of diseases progression and the development of new therapeutics. Thus, this symposium aims at discussing these key aspects, together with new concepts to advance the replacement or regeneration of kidney function and the current developments towards the clinical application.
**Symposium Title**  
Landscape of regenerative medicine and tissue engineering in Russia

**Symposium Organisers**  
Peter Timashev, Institute for Regenerative Medicine, Sechenov University, Russia  
Email: timashev.peter@gmail.com

Valerian Kagan, Department of Environmental and Occupational Health, University of Pittsburgh, United States of America  
Email: kagan@pitt.edu

**Symposium Summary**  
In the last decade, Russia has become an active player in the field of tissue engineering and regenerative medicine, and the amount of corresponding publications and clinical trials annually increases. The government has started to create the required environment to enhance research in this field and its clinical translation by passing the new law regulating the production of biomedical cell products and acting from 2017. Due to historical background, tissue engineering and regenerative medicine in Russia differ from other countries and are strongly connected with physics (especially laser technologies), material science, and mathematics. Now, Russia with its distinctiveness mainly formed in the USSR during the Iron Curtain period is opened to collaborations with scientists from all over the world giving a birth to the new generation of scientists who work in the field of tissue engineering and regenerative medicine and creating non-trivial approaches. This symposium will discuss key achievements by Russian scientists and their place in the world science and medicine.
Symposium Title
Modulating macrophages for materials-driven in situ tissue regeneration: A personalized approach?

Symposium Organisers
Yvonne M. Bastiaansen-Jenniskens, Department of Orthopedics, Erasmus MC University Medical Center, Rotterdam, The Netherlands
Email: y.bastiaansen@erasmusmc.nl

Anthal I.P.M. Smits, Soft Tissue Engineering and Mechanobiology Group, Department of Biomedical Engineering & Institute for Complex Molecular Systems (ICMS), Eindhoven University of Technology, Eindhoven, The Netherlands
Email: a.i.p.m.smits@tue.nl

Symposium Summary
The immune system plays a commanding role in tissue regeneration, as well as the host response to implanted biomaterials. Macrophages in particular have been identified as a pivotal cell type in these processes; they dictate both the deposition and remodelling of extracellular matrix in close cross-talk with tissue-forming cells (e.g. (myo)fibroblasts, mesenchymal stromal cells), and drive the degradation of biomaterials by secreting reactive oxygen species and enzymes. This recognition has led to the development of immunomodulatory biomaterials for a wide range of clinical applications, including orthopaedic and cardiovascular replacements, which are designed to steer macrophage behaviour as such to harness the evoked inflammatory response and promote the regeneration of functional tissue in situ. The modulation of macrophage phenotype is dependent on local biomaterial properties (e.g. microstructure), as well as environmental factors, such as biochemical and biomechanical cues. While proof-of-concept studies highlight the potential of such macrophage-centered materials-driven regeneration approaches, these strategies rely heavily on the intrinsic regenerative capacity and –related to that- the immunological condition of the patient. Patient-specific factors, such as age, sex and systemic comorbidities (e.g. diabetes and obesity) have a profound effect on the inflammatory response to an implanted biomaterial, and, therefore, the long-term outcome. This symposium will discuss the potential of immunomodulatory materials for in situ regeneration, with a focus on macrophages, and will explore the potential need and opportunities for employing a personalized approach therein in the pursuit of developing robust clinical treatments.
Symposium Title
MSC-derived extracellular vesicles: From production, engineering and administration challenges to bone tissue regenerative therapies

Symposium Organisers
Catherine Le Visage, INSERM UMRS 1229, Regenerative Medicine and Skeleton (RMeS), Nantes University, School of Dental Surgery, Nantes, France
Email: catherine.levisage@inserm.fr

Halima Kerdjoudj, EA 4691 BIOS (Biomaterials and Inflammation in Bone Site), University of Reims, France
Email: halima-assia.kerdjoudj@univ-reims.fr

Symposium Summary
Extracellular vesicles (EVs) play a crucial role in cell to cell communication, as they transmit encapsulated biological materials such as transcriptional regulators, RNA and lipids, from donor cells to recipient cells. Growing evidence also suggests that Mesenchymal Stem Cell (MSC)-derived EVs could partially mimic the role played by their originating cells and act as delivery vehicles of bioactive molecules. This symposium will i) address current strategies to harness the biological functions of natural EVs as delivery vehicles, specifically dealing with biological and practical concerns for the production and purification of these systems, and (ii) present recent data on the emerging role of EVs in the natural tissue formation process, in the context of tissue repair and regeneration.
Symposium Title  
Musculoskeletal organoids for disease modelling and personalized therapies  

Symposium Organisers  
Ralph Mueller, Laboratory for Bone Biomechanics, ETH Zürich, Switzerland  
Email: ram@ethz.ch  

Marina Rubert, Laboratory for Bone Biomechanics, ETH Zürich, Switzerland  
Email: marina.rubert@hest.ethz.ch  

Daniel J. Kelly, Trinity Center for Bioengineering, Trinity College of Dublin, Ireland  
Email: KELLYD9@tcd.ie  

Symposium Summary  
There is an increasing need for development of human-representative models allowing the direct  
translation of therapies for musculoskeletal tissues from bench-to-bed. Musculoskeletal organoids  
aim to recapitulate musculoskeletal functions and processes from molecular to the cellular, or organ  
level. Musculoskeletal organoid formation is regulated by biochemical and biomechanical signals,  
cell-cell cross-talks and characterized by the self-ability of cells to be organized into 3D structures  
resembling in vivo tissues. The interaction of these factors needs to be spatially and temporally  
coordinated and guides the differentiation of stem cells and self-assembly of cells in organoids.  
Furthermore, musculoskeletal organoids must fulfil their mechanical function. Last but not least, to  
enhance control of organoids and further modulate the system for downstream applications,  
systematic engineering approaches are needed. To this end, cell source, organization, engineering of  
different scaffold types and cell-cell/cell-matrix interactions within these systems resembling the  
native musculoskeletal tissues structures and activities are investigated. In this symposium, we will  
discuss the current approaches to fabricate functional musculoskeletal models and methods used to  
track the development and functionality of the generated organoid. Furthermore, relevance of  
generation of musculoskeletal disease organoids using patient-derived cells to provide understanding  
of exact disease pathomechanisms behind each individual and facilitate the implementation of  
personalized therapies will be further discussed.
Symposium Title
Natural polymers in tissue engineering applications, the future of regenerative medicine

Symposium Organisers
Ipsita Roy, Applied Biotechnology Research Group, School of Life Sciences, College of Liberal Arts and Sciences, University of Westminster, London W1W 6UW, United Kingdom
Email: royi@wmin.ac.uk

Jochen Salber, University Medical Centre Knappschaftskrankenhaus, Clinic of Surgery, Bochum, Germany
Email: jochen.salber@hotmail.com

Symposium Summary
Natural Polymers have been known for their unusual biocompatibility and regenerative properties. As opposed to synthetic polymers, they also provide a sustainable solution to the area of medical materials. The current medical materials in the clinic include PEEK, silicone, PET, amongst the non-biodegradable; and PLLA, PLGA and PCL, amongst the biodegradable. Collagen, chitosan, chitin, alginate, gelatin, Polyhydroxyalkanaotes, Bacterial cellulose, -Polyglutamic Acid are examples of natural polymers that are known for their excellent regenerative properties and hence can easily replace and improve the functionalities of the synthetic polymers in tissue engineering scaffolds. These polymers have the potential to have a huge impact in the area of medical materials and indeed the ability to regenerate tissues and organs in the lab in the near future. In this Symposium we will focus on the use of Natural Polymers in the area of Tissue Engineering including areas such as nerve, skin, cardiac, bone, cartilage, pancreas, liver, brain and the urinary bladder. The applications could involve the use of natural polymer-based materials, and hence could include blends, composites with other synthetic polymers, organic and inorganic fillers. The clinical feasibility of the use of this family of polymers and the time required for implementation in the clinic will also be critically addressed.
Symposium Title
Natural-based bioinks for biofabrication of personalised implants and tissue engineering

Symposium Organisers
J Miguel Oliveira, 3B's Research Group, I3Bs - Research Institute on Biomaterials, Biodegradables and Biomimetics, University of Minho, Headquarters of the European Institute of Excellence on Tissue Engineering and Regenerative Medicine, AvePark, Parque de Ciência e Tecnologia, Zona Industrial da Gandra, 4805-017 Barco, Guimarães, Portugal
Email: miguel.oliveira@i3bs.uminho.pt

Maurice N Collins, Stokes Laboratories, Bernal Institute, School of Engineering, University of Limerick, Ireland
Email: Maurice.Collins@ul.ie

Symposium Summary
3D printing is a well-established technology and it has attracted interest from clinicians, as it offers a wide range of personalised treatments. Despite high expectations within the field, clinical translation of bioprinted scaffolds and implants is scarce due to the limited performance of reported bioinks. Bioplotting has tended to focus on the technology itself rather than on materials development and therefore there are many technical opportunities to move these materials/inks to higher performance levels. Current deposition and fabrication technologies allow researchers to design and build structures with increasingly intricate architectures. However, in achieving this, many concessions have been made regarding the biological aspects of the hydrogels. As a possible solution novel protein- and polysaccharide-based biomaterials of natural-origin have been engineered to obtain biomimetic and fast-curing bioinks which are suitable for bioprinting and tissue engineering applications, namely as scaffolds and patient-specific implants. This symposium will be dedicated to several significant contributions concerning the development naturally derived bioinks including enzymatic, ionic, photo-crosslinking and reinforcement strategies. Aspects of materials selection, design and printing parameters will be discussed in terms of structure/property/printing relationships in order to produce bioprinted structures with higher spatial resolution. Examples of pre-clinical validation will be provided in the context of musculoskeletal tissue regeneration. In addition, future perspectives and the outlook on utilising imaging techniques (e.g. MRI) in conjunction with 3D printing will be discussed. The symposium proposers are committed to the development of early career researchers (ECRs) and therefore two slots will be dedicated to ECRs whilst ensuring gender balance.
Symposium Title
Nervous system repair – Paradigms, challenges and lessons for clinical translation

Symposium Organiser
Richard D Bartlett, UCL Centre for Nerve Engineering, University College London, United Kingdom
Email: richard.bartlett.11@ucl.ac.uk

Symposium Summary
Cajal first noted the ability of the nervous system to regenerate over 100 years ago, yet approved clinical therapies for nervous system repair remain extremely limited. There are a plethora of cutting-edge regenerative medicine and tissue engineering technologies aimed at regenerating the damaged nervous system, but translation of these ideas into clinical practice has remained a significant challenge. Factors that can cause bottlenecks in this translational pathway are numerous, but considerations spanning multiple disease areas include scale-up and commercialisation, regulatory classification and safety, use of an appropriate preclinical testing model, and correctly identifying a suitable patient population for early phase clinical trials. This symposium will discuss how to overcome such challenges, with the aim of moving promising regenerative medicine technologies to first-in-human phase. This symposium will cover a range of issues, giving unique insights in how to progress from concept development, through to preclinical testing, industrial partnership, and early phase clinical trials. Further, this symposium will include examples of regenerative medicine therapies that have reached first-in-human phase for nervous system repair and offer reflections on the lessons that can be applied for the future.
Symposium Title
New frontiers in osteoarthritis treatment: Prospects for stem cells, extracellular vesicles and biomaterials-assisted cell therapies

Symposium Organisers
Claire Vinatier, INSERM UMRS 1229, Regenerative Medicine and Skeleton (RMeS), Nantes University, School of Dental Surgery, Nantes, France
Email: claire.vinatier@univ-nantes.fr

Anne Des Rieux, UCLouvain, Louvain Drug Research Institute, Advanced Drug Delivery and Biomaterials Unit, Avenue Mounier, 73 bte B1.73.12, 1200 Brussels, Belgium
Email: anne.desrieux@uclouvain.be

Symposium Summary
Osteoarthritis (OA) is the most common debilitating joint disease. OA is associated with inflammation, alteration of joint tissues and disabling pain. Current treatments allow at best pain relief but do not prevent joint degeneration. To address this clinical issue and propose new relevant therapeutic options for the increasing number of OA patients, the intraarticular (IA) injection of Mesenchymal Stem Cell (MSCs) derived from bone marrow or adipose tissue have recently been proposed as a promising approach. Indeed, MSCs have regenerative capabilities via the direct or vesicles-mediated secretion of trophic factors that exhibit immunomodulatory, anti-apoptotic, anti-fibrotic and potent anti-inflammatory activities. In preclinical and clinical studies, the IA injection of MSCs is safe, well tolerated and to a certain extent able to limit OA progression. However, the IA injection of “naked” MSCs exhibits two major limitations: (i) a massive cell death upon injection and (ii) a cell leakage outside of the joint space. Both limits lead to an ephemeral presence of MSC in the joint that could impair their long-term efficacy. In this context, this symposium proposal aims at addressing this unmet medical need.
**Symposium Title**

New Horizons in targeted heart regeneration through multidisciplinary strategies

**Symposium Organisers**

Gianluca Ciardelli, Department of Mechanical and Aerospace Engineering, Politecnico di Torino, Italy  
Email: gianluca.ciardelli@polito.it

Monica Boffito, Department of Mechanical and Aerospace Engineering, Politecnico di Torino, Italy  
Email: monica.boffito@polito.it

**Symposium Summary**

Heart failure following myocardial infarction is the current leading cause of mortality and morbidity in the industrialised world with more than 26 million cases worldwide and a survival rate of only 50% within 5 years from diagnosis. Despite the significant advancements in pharmaceutical and interventional therapies, the irreversible loss of functional cardiomyocytes (CMs) after myocardial infarction represents one major barrier to heart regeneration and functional recovery. Up to now the combination of different cell sources and biomaterials have been investigated to generate CMs by differentiation or reprogramming approaches although at low efficiency. New biomaterial platforms integrating biochemical instructive cues and external physical cues may represent a key tool for the effective generation of functional CMs. In more detail, induced pluripotent stem cell derived -CMs can be obtained with superior efficiency on biomimetic scaffolds, integrated with electrical and mechanical stimuli in controlled culture microenvironments in *in vitro* tissue engineering approaches. In this regard rapid prototyping techniques may be used for reproducible and controlled engineering of cellularised scaffolds integrating multiple biochemical signals. On the other hand, *in vivo* approaches are under development based on advanced minimally invasive injectable biomaterial platforms for the delivery of cells or bioactive factors as well as for targeted gene therapy inducing direct reprogramming of specific local cells. This symposium will discuss these new supradisciplinary *in vitro* and *in vivo* approaches and elucidate how the newly developed knowledge will enable clinical translation and commercialisation of therapies for heart regeneration in the years to come. Latest contributions on the role of experimental *in vitro* models of the myocardial tissue in this scenario to test pharmaceutical and regenerative approaches will be also welcome.
Symposium Title
Open Up! Chances and limitations of using open innovation in science

Symposium Organisers
Benjamin Missbach, LBG Open Innovation in Science Center, Ludwig Boltzmann Gesellschaft (LBG), Austria
Email: benjamin.missbach@lbg.ac.at

Veronika Hruschka, Ludwig Boltzmann Institute for Experimental and Clinical Traumatology, AUVA Research Centre, Austria
Email: veronika.hruschka@trauma.lbg.ac.at

Symposium Summary
Open research in clinical settings not only refers to open data or open access research artefacts (e.g.: open access publications, open data, open peer-review), but it also includes openness during the entire research flow: From identifying research questions, co-creating study designs with relevant stakeholders, implementing research with patients reported outcomes sets, and utilizing research data for translating scientific knowledge into innovation. This all can lead to an increase in societal impact and the relevance to industrial and clinical applications. Open collaboration during one or several of those phases can involve citizen science, multidisciplinary research or strengthen the link between academia, industry and market needs. In order to follow this avenue of opening research, traditional scientific approaches need to be adapted and re-thought. This symposium will discuss various open research approaches and present the advantages, drawbacks, limitations and chances to sustainably integrate the “open” in science.
Symposium Title
Regenerative therapies for the intervertebral disc

Symposium Organiser
Max H.P. Gay, Department of Biomedicine & Department of Spinal Surgery, University Hospital Basel, Switzerland
Email: max.g@unibas.ch

Benjamin Gantenbein, Department for BioMedical Research (DBMR), University of Bern, Switzerland
Email: Benjamin.gantenbein@istb.unibe.ch

Symposium Summary
The intervertebral disc (IVD) of the spinal column represents a major challenge for successful biological and tissue-engineered treatments. Alternatives, to the surgical “gold standard”, which is discectomy followed by spinal fusion are urgently warranted. This session calls for recent advances in approaching regeneration of the IVD using a combination of biomaterials with or without cells. A focus of the seminar will be the search for ideal cell sources for cell therapy and bioactive compounds or manipulation (e.g. growth factors, peptides, gene therapy). Due to the nature of the IVD, it is important to distinguish between repair of the annulus fibrosus repair and of the nucleus pulposus. These two tissue types require each a different strategy and likely require composite materials for a combined repair. Clinical translation of cell therapy seems challenging as cell source is essential and fate and effects of transplanted cells often is difficult to track.
Symposium Title
Regenerative therapies for the treatment of Parkinson’s disease

Symposium Organiser
Eilis Dowd, Dept of Pharmacology, National University Ireland Galway, Ireland
Email: Eilis.Dowd@nuigalway.ie

Symposium Summary
The symposium will explore cross-disciplinary approaches for the treatment of Parkinson’s disease (PD). The symposium will explore the development of functionalized biomaterials using stem cells and/or bioactive molecules to target the neuroinflammatory and neurodegenerative phases of the underlying pathology of PD. The talks will present preclinical findings and current state-of-the-art biomaterial-based systems and will include a wide range of disciplines such as tissue engineering, material science, prototype design, functionalisation, and in vivo/ex vivo model systems and lab-on-a-chip systems.
Symposium Title
Rejuvenation of regenerative capacity in aged cells

Symposium Organisers
Rocky S. Tuan, Institute for Tissue Engineering and Regenerative Medicine, The Chinese University of Hong Kong, Hong Kong S.A.R., China
Email: tuanr@cuhk.edu.hk

Hang Lin, Center for Cellular and Molecular Engineering, Department of Orthopaedic Surgery, University of Pittsburgh School of Medicine, United States of America
Email: hal46@pitt.edu

Symposium Summary
Humans possess varied and diverse capacity to regenerate damage tissues, which however declines with the advancement of age. Aging of cells is marked by shorting of telomeres, DNA damage, oxidative stress, and deregulation of specific genes and proteins, which together causes reduced cellular proliferation capacity and reparative activities. In particular, aging affects the number and potential of resident stem cells. In addition to influencing cells, aging also causes alterations of the local and systematic environment, such as changing the composition of extracellular matrix (ECM) and increasing global low-grade inflammation, which may further attenuate the regeneration process. Currently, the nature and underlying mechanisms of regenerative decline during aging are poorly understood. In this symposium, the basic biology of aging and the potential strategies to augment regeneration in the aged individuals will be discussed.
**Symposium Title**
Research challenges in stem cell culture and differentiation on biomaterials targeting for stem cell therapy

**Symposium Organiser**
Akon Higuchi, Department of Chemical and Materials Engineering, National Central University, Taiwan
Email: higuchi@ncu.edu.tw

**Symposium Summary**
There is a shortage of tissues and organs for patients who suffer damage or loss of their tissues and organs. Stem cells hold promise for drug discovery and regenerative medicine. The development of a fully defined microenvironment for culturing human stem cells will have a great effect on the use of stem cells in cell therapy and tissue engineering. In this session, we will discuss the design and strategy of biomaterials for stem cell culture and differentiation. Especially, we will discuss biomaterial designs, which maintain the pluripotency of human embryonic stem cells and induced pluripotent stem cells in xeno-free cell culture conditions and the biomaterials that guide differentiation of stem cells (adult stem cells, fetal stem cells, human embryonic stem cells, and human induced pluripotent stem cells) into specific lineages of cells. We will also discuss the biomaterials used in clinical application using stem cells. Additionally, we will discuss the translational development of cell therapies in various catastrophic illnesses. Target Audience is (a) Biomaterial researchers who are investigating human stem cell culture and differentiation, (b) Medical doctors who are investigating translational development of cell therapies, (c) Medical Doctors who are investigating clinical trials based stem cells.
Symposium Title
RSC Biomaterials Chemistry Group - Innovative materials for tissue engineering and regenerative medicine

Symposium Organisers
Alberto Saiani, School of Materials, University of Manchester, United Kingdom
Email: A.Saiani@manchester.ac.uk

Steve Rimmer, School of Chemistry and Biosciences, University of Bradford, United Kingdom
Email: S.Rimmer@bradford.ac.uk

Symposium Summary
The RSC Biomaterials Chemistry Group brings together chemists working in close collaboration with engineers, biologists, materials scientists and clinicians. This symposium will showcase key expertise in the area of synthetic smart biomaterials, with a focus on the development and characterisation of innovative materials to model and control physiologically relevant environments. It is anticipated that this symposium will provide an ideal forum for contributing presenters who wish to showcase research on new biomaterials. We anticipate that the audience who will benefit most from this symposium would be academic, industrial and clinical partners wishing to be more involved in biomaterials research advances.
Symposium Title
Setting hydrogels to promote angiogenesis

Symposium Organiser
Sandra Van Vlierberghe, Polymer Chemistry & Biomaterials Group, Centre of Macromolecular Chemistry, Department of Organic and Macromolecular Chemistry, Ghent University, Belgium
Email: Sandra.VanVlierberghe@UGent.be

Symposium Summary
In human tissue and organs, healthy cells are always closer then few hundred microns from nutrients and blood. Microcirculation is essential to preserve cell viability and to ensure tissue repair through a dense and extensive networks of micro-vessels (capillaries) through which metabolites and catabolites are continuously renewed. The development of these micro-vessels is also referred to as angiogenesis. Angiogenesis is mandatory anywhere in the presence of cells, where their growth and activity are expected to provide important features to tissue engineering scaffolds, especially after maturation in bioreactors, in soft, hard or connective tissue, for any application of Regenerative Medicine and for implants in particular. This symposium will discuss the key factors of hydrogels which modulate the in vitro microenvironment and elucidate how the newly developed knowledge will enable clinical translation and commercialisation of cell-based therapies in the years to come, and more specifically, how hydrogels can contribute to angiogenesis associated with implants thereby contributing to reducing implant failure.
Symposium Title
Smart biofabrication

Symposium Organisers
Peter Timashev, Institute for Regenerative Medicine, Sechenov University, Russia
Email: timashev.peter@gmail.com

Yuri Rochev, School of Chemistry, Centre for Research in Medical Devices (CÚRAM), National University of Ireland Galway (NUI Galway), Ireland
Email: yury.rochev@nuigalway.ie

Symposium Summary
Nowadays, the existing approaches limit the development of biofabrication, and new ones are under investigation. The technology combining biomaterials and cell self-assembled structures such as cell spheroids and sheets is offered as the most promising one forming a term “smart biofabrication”. It allows scientists to fabricate 3D complex structures with high cell density and preformed cellular junctions with the possibility of self-inducing cell differentiation. While the number of studies utilizing this technology is constantly growing, it is essential to provide a framework of its main issues and achievements. This symposium will discuss them and their further application in fabrication of tissues and organs using cell sheets and spheroids.
Symposium Title
Stem cell therapies 4.0 for musculoskeletal regeneration

Symposium Organisers
Andreas Traweger, Institute of Tendon and Bone Regeneration, Paracelsus Medical University, Spinal Cord Injury and Tissue Regeneration Center Salzburg (SCI-TReCS), Salzburg, Austria
Email: andreas.traweger@pmu.ac.at

Darja Marolt Presen, Ludwig Boltzmann Institute for Experimental and Clinical Traumatology, Austrian Cluster for Tissue Regeneration, Vienna, Austria
Email: darja.marolt@trauma.lbg.ac.at

Symposium Summary
Regeneration of musculoskeletal tissues can present significant challenges, particularly in patients with decreased regenerative capacity due to extensive trauma, diseases and advanced age. In the past, many research efforts have been focused on development of cell therapies employing mesenchymal stromal/stem cells (MSCs) or MSC-based musculoskeletal tissue engineering. However, more recently there has been a shift in the view of MSCs as cells directly contributing to tissue regeneration to “cell factories” producing a variety of bioactive molecules, extracellular vesicles and tissue/extracellular matrix components that can be employed as therapeutic modalities without the disadvantages of classical cell therapy. This symposium will present and discuss recent developments and the state of the art in these “Stem cell therapies 4.0” for musculoskeletal tissues regeneration, from the production, characterization, understanding of their mechanisms of action and their potential to enhance the endogenous populations toward improved tissue regeneration, as well as the interplay with the systemic environment. In addition, challenges on route to clinical translation and future perspective of this exciting field will be discussed.
Symposium Title
TEDD symposium on industrial engineering of 3D tissues models – I. Building physiology for drug development and substance testing

Symposium Organisers
Michael Raghunath, Center for Cell Biology and Tissue Engineering, Institute of Chemistry and Biotechnology, Zurich University of Applied Sciences (ZHAW), Switzerland
Email: ragh@zhaw.ch

Susan Gibbs, Dept. Molecular Cell Biology and Immunology, Amsterdam University Medical Center, Location VUMC, Amsterdam, The Netherlands
Email: s.gibbs@vumc.nl

Symposium Summary
Conceptual advances in cell biology are strongly suggesting moving from “flat biology” towards using 3D models, encompassing ultraflat monolayer system, stacked systems such as skin, but also microtissues, arising from self-assembled cells (spheroids) or assembled via different modes of bioprinting. Based on the argument that 3D tissue systems are more mature and functional via cell-cell and cell-extracellular matrix contacts, they are also gaining traction in scaffold-free bioprinting efforts to build tissue. The question with all the models is how well are they emulating physiology, and how complicated must they get to satisfy industrial needs? We shall be discussing the bandwidth of relatively straightforward biophysical approaches to boost physiology in standard culture systems for drug screening, but also will have a look at the challenging task to emulate a robust cellular cross-talk in more complex systems for predictive drug and substance testing.
Symposium Title
TEDD symposium on industrial engineering of 3D tissues models II. What industry really wants and needs

Symposium Organisers
Michael Raghunath, Center for Cell Biology and Tissue Engineering, Institute of Chemistry and Biotechnology, Zurich University of Applied Sciences (ZHAW), Switzerland
Email: ragh@zhaw.ch

Jens M. Kelm, PreComb Therapeutics AG, Einsiedlerstrasse 30, CH-8820 Wädenswil, Switzerland
Email: Jens.kelm@precomb.com

Symposium Summary
Conceptual advances in cell biology are strongly suggesting moving from “flat biology” towards using 3D microtissues, arising from self-assembled cells (spheroids) or assembled via different modes of bioprinting. Tissue engineering of 3D models of human tissue for industrial purposes has remained a challenge, because beautiful images shown in prestigious journals are one thing, while the robustness of these models remains another. 3D cell culture technologies are considered in industry circles to have a high impact on the efficiency of drug discovery and development. However, despite accepting that advanced tissue culture models from high throughput to multi-organ technologies reflect the in vivo biology better than traditional culture systems, implementation of these models is still in its infancy. We will shed light on the requirements that industry has for 3D models including scalability, robustness and validation issues. Where do we stand right now? Will harmonization of the model/technology validation be helpful? We will discuss that is may be time for a bed to bench approach to better achieve pharmacologically more predictive 3D tissue models, and that this will require a different collaborative approach with clinicians.
Symposium Title
The promise of perinatal cells in regenerative medicine

Symposium Organisers
Ornella Parolini, Università Cattolica del Sacro Cuore, Rome, Italy and Centro di Ricerca E. Menni, Fondazione Poliambulananza-Istituto Ospedaliero, Brescia, Italy
Email: ornella.parolini@unicatt.it

Hassan Niknejad, Nanomedicine and Tissue Engineering Research Center, Shahid Beheshti University of Medical Sciences, Tehran, Iran
Email: niknejad@sbmu.ac.ir

Symposium Summary
Regenerative medicine aims to repair and regenerate damaged cells, tissues, and organs in order to restore function. It can be obtained either by direct cell replacement or by favoring tissue integrity and stimulating resident stem cells. To date, several promising strategies are being heavily investigated to enhance regeneration and these include cell-based therapies and cell-based tissue engineering for customized and functional tissue regeneration. Amongst the sources of stem cells used in regenerative medicine approaches, perinatal tissues, such as the human term placenta and the amniotic fluid, offer robust potential, while avoiding the controversy associated with embryonic or induced pluripotent stem cells. This symposium will elucidate applications of perinatal derivatives in regenerative medicine approaches. The discussion will include basic research that explores potential new therapeutic applications, to the current investigations of perinatal derivatives in clinical trials.
**Symposium Title**
The road towards bioengineering of functional skeletal muscle

**Symposium Organisers**
Daniel Eberli, University Hospital of Zürich, Urology Clinic, Frauenklinikstrasse, 10, CH-8091, Zürich, Switzerland
Email: daniel.eberli@usz.ch

Bert Mueller, University of Basel, 4123 Allschwil, Gewerbestrasse 14, Switzerland
Email: bert.mueller@unibas.ch

**Symposium Summary**
Musculoskeletal damage due to injury or disease often results in impaired endogenous tissue regeneration and revascularization. Cell therapy is a promising approach to restore cellular function in muscular diseases. The quality of the early regenerated tissue is crucially important for its proper function and thus, many efforts have been taken to facilitate in vivo tissue development and cell survival. Despite partial success in animals and human studies, further research is required before wide-spread clinical application can take place. Amongst the many promising attempts for long-term improvement of bio-engineered muscle, include implantation of biomaterial scaffold for host cell guidance, neuromuscular electromagnetic stimulation (NMES) and vascularization to improve tissue function upon treatment and to enhance the incorporation of bioengineered tissue.
Symposium Title
Tissue engineering and regenerative therapies in ophthalmology

Symposium Organisers
Mark Ahearne, Trinity Centre for Bioengineering, Trinity Biomedical Sciences Institute, Trinity College Dublin, University of Dublin, Ireland
Email: ahearnm@tcd.ie

Samantha L Wilson, Centre for Biological Engineering, Wolfson School Manufacturing Electrical and Mechanical Engineering, Loughborough University, United Kingdom
Email: s.wilson2@lboro.ac.uk

Symposium Summary
Blindness and impaired vision affects millions worldwide. Macular degeneration, glaucoma, cataracts, trachoma and corneal dystrophies are just some of the more common conditions that can result in a loss of vision, significantly reducing the patients quality of life. To overcome these condition the novel tissue engineering strategies and cell based regenerative therapies to restore vision are vital. This symposium will examine recent progress made in the development of regenerative therapies for ocular conditions and their clinical translation. The recent progress made in biofabricating tissues to replace damaged ocular tissue or repair defects will be highlighted during the symposium. The developments in stem cell therapies for retinal, macular and corneal epithelial regeneration will be discussed. The symposium will also examine the production and clinical application of novel biomaterials suitable for use as ocular implant, cell carriers or corneal replacements. Both on-going and completed clinical trials involving the translation of cell based ocular therapies, biomaterials and tissue engineered products for the eye will be discussed. This symposium will provide a useful platform to bring together leading scientists and clinicians in the field of ocular regeneration as well as being of interest to the wider TERMIS community.
Symposium Title
Tissue engineering under external stimulus

Symposium Organisers
Gianni Ciofani, Polytechnic University of Torino, Department of Mechanical and Aerospace Engineering & Italian Institute of Technology, Department of Smart Bio-Interfaces, Italy
Email: gianni.ciofani@iit.it

Sandra Camarero-Espinosa, MERLN institute for Technology Inspired Regenerative Medicine, University of Maastricht, The Netherlands
Email: s.camarero-espinosa@maastrichtuniversity.nl

Symposium Summary
Tissue engineering requires the development of physiologically relevant cell microenvironments to drive cell lineage commitment and functional tissue formation. Scientific research has traditionally been focused on the exploitation of biochemical signals such as growth factors, media supplements, etc., or on physical cues such as topography, material mechanical properties, etc., in the case of scaffold-based cell therapies, to promote cell commitment to specific phenotypes. However, these are generally not sufficient to fully mimic or provide cells with an optimal microenvironment where they can differentiate towards specific and well-defined phenotypes. To this end, scientist have recently started to investigate the potential of other stimuli such as electrical, acoustic, mechanical (external dynamic loading) or vibrational, that can be applied externally and enhance cell differentiation and tissue formation. This symposium will discuss the state-of-the-art and future directions of key external cell stimulation strategies (vibrational, electrical, acoustic, mechanical, etc.), biomaterials and devices developed to this end, and the impact of these onto cell differentiation and tissue formation. The symposium will also discuss the potential clinical translation and commercialization of these novel strategies.
**Symposium Title**  
Tissue-specific, therapeutic biomaterials for personalized, minimally-invasive regenerative medicine treatments: Lessons from “circular translation”

**Symposium Organisers**  
Matteo Santin, Director of the Centre for Regenerative Medicine and Devices (CRMD), School of Pharmacy & Biomolecular Sciences, University of Brighton, United Kingdom  
Email: m.santin@brighton.ac.uk

Maria Grazia Raucci, Institute of Polymers, Composites and Biomaterials, National Research Council, Italy  
Email: mariagrazia.raucci@cnr.it

**Symposium Summary**  
Cell therapy, gene therapy and tissue engineering have opened avenues to efficacious treatments of diseased or traumatised tissues whereby the traditional concept of tissue ‘re-placement’ by one-implant-for-all is superseded by the goal of personalised tissue ‘re-generation’. In all these three approaches biomaterials are a key enabling technology either as carriers of cells and genes or as extracellular matrix-mimicking scaffolds. The clinical potential of novel biomaterials in regenerative medicine becomes even more appealing when designed to enable minimally-invasive clinical procedures. On the basis of these premises, the development of biomaterials that can combine injectability properties or nano-sized features to tissue-competence and/or tissue specificity becomes a high R&D priority. While transforming the clinical outcome for many challenging clinical conditions, such systems will reduce patients’ distress and recovery time and in the long-term lead to reduced costs of treatment for the health system. This symposium will discuss the clinical potential and industrial feasibility in different types of regenerative medicine treatments; cell therapy of heart tissue regeneration and tissue engineering for bone regeneration. The symposium will introduce the concept of injectable, therapeutic biomaterials in the light of models of ‘circular translation’ whereby clinical and industrial feedbacks refine lab-driven innovation.
**Symposium Title**
Transformation of design thinking in a 3D printing world

**Symposium Organisers**
Patrina S. P. Poh, Julius Wolff Institute, Charité, Universitätsmedizin Berlin, Berlin, Germany
Email: patrina.poh@charite.de

Navid Khani, BellaSeno GmbH, Leipzig, Germany
Email: Navid.khani@bellaseno.com

**Symposium Summary**
In the field of healthcare, the strength of additive manufacturing (AM) technologies lies in the possibility to produce personalised biomedical products. However, there are still many challenges which need to be addressed to establish a new gold standard for the design, optimisation and fabrication of a personalised biomedical products while ensuring functionality. This is because the complexity of the human body has added another dimension of challenges in adoption of AM in the healthcare field - as bioengineers not only have to consider the physical and manufacturing requirements, yet also the biological and clinical requirements to ensure functionality. We believe that innovative solutions for the advancement of R&D in the field of AM for regenerative therapy require interdisciplinary collaborations. This symposium is a joint session between scientists in academia and industry in order to arrive at a common understanding and foster the translation of ideas to consumer products. In particular, the freedom to manufacture almost any shape opens the possibility for the development of various products with respect to target objective (i.e. regeneration of bone/ cartilage/ breast etc.). This symposium will provide an insights into the transformation of research ideas to consumer products - thus inspiring young scientists to transform laboratory-born ideas into real-world impact.
Symposium Title
Vascularization for TERM

Symposium Organisers
Andrea Banfi, Department of Biomedicine, Basel University Hospital, Basel, Switzerland
Email: andrea.banfi@usb.ch

Wolfgang Holnthoner, LBI for Experimental and Clinical Traumatology, Vienna, Austria
Email: wolfgang.holnthoner@trauma.lbg.ac.at

Symposium Summary
Rapid vascularization is of vital importance for survival and function of tissue-engineered grafts of clinically relevant size. Oxygen and nutrient supply/waste removal, interstitial fluid drainage, as well as control of its composition and of oncotic pressure, are ensured by the formation of pervasive microcapillary networks derived from blood and lymphatic vascular endothelial cells, respectively, that need to connect with the host vascular systems. Furthermore, functional vascularization needs to be established within days of in vivo implantation to allow survival of progenitors and effective tissue formation. Lastly, the crucial role of immune cells in regulating vascular formation and function, as well as tissue regeneration, is increasingly appreciated. This symposium will discuss current in vitro and in vivo strategies to construct blood and lymphatic vascular networks, linking vascular biology principles to bio-inspired technological approaches to translational aspects. Topics will include: 1) angiogenesis mechanisms and control of biological signals; 2) gene transfer for angiogenesis; 3) immunological aspects of tissue vascularization; 4) pre-vascularization strategies, including co-culture systems of endothelial cells with other supporting cell types; 5) biomaterial-based control of vascularization, including de- and re-cellularized matrices. The Symposium should be of interest to both academic and industry scientists from a broad variety of backgrounds, including Tissue Engineering, Vascular Biology, Cardiovascular Medicine and Biomaterial Development.
Symposium Title
Veterinary tissue engineering and regenerative medicine – animal models

Symposium Organisers
Iris Ribitsch, Equine Clinic, Veterm, Vetmeduni Vienna, Austria
Email: Iris.ribitsch@vetmeduni.ac.at

Louis Penning, Faculty of Veterinary Medicine, Clinical Sciences of Companion Animals, University Utrecht, The Netherlands
Email: L.C.Penning@uu.nl

Symposium Summary
The similarities of many naturally-occurring diseases with their equivalents in humans makes the veterinary sector a valuable ‘proving ground’ for novel techniques involving regenerative medicine and tissue engineering. Main goal of this symposium is therefore to provide expertise regarding animal models with special emphasis on large animal models and naturally occurring diseases with similar aetiopathogenesis and pathophysiology as encountered in human patients offering an update on recent developments in veterinary regenerative medicine using validated animal models.
Symposium Title
Veterinary tissue engineering and regenerative medicine – Clinical applications

Symposium Organisers
Iris Ribitsch, Equine Clinic, Veterm, Vetmeduni Vienna, Austria
Email: Iris.ribitsch@vetmeduni.ac.at

Xavier Donadeu, Roslin Institute, University of Edinburgh, United Kingdom
Email: xavier.donadeu@roslin.ed.ac.uk

Symposium Summary
Despite the “One health, one Medicine” concept, clinical knowledge is often not exchanged between the veterinary and human medicine communities. However, many natural occurring diseases encountered in humans also pose a problem in veterinary patients with similar pathology and aetiopathogenesis. These diseases certainly raise the interest in regenerative medical treatments from the veterinary profession but, at the same time, offer not only a relevant translational model for human patients, but also one that is better than artificially created diseases models which do not accurately reflect the clinical situation. Following the idea of “One Health” for expanding interdisciplinary collaborations for the development and evaluation of new methods for the prevention and control of diseases across species (humans and animals), the veterinary profession has an active role in translating regenerative medicine into the clinic. Data and experience obtained from treating veterinary patients with regenerative medicine based treatment strategies can serve as preclinical data for the human medicine field. In this proposed session translational aspects and results from veterinary TERM clinical cases and veterinary TERM clinical trials will be discussed which will provide valuable comparative insight into clinical outcome / problems / challenges / needs / prospects related to the rapidly expanding field of TERM.
Symposium Title
Wound healing in 2020: Where basic science meets clinical needs

Symposium Organisers
Alexandra P Marques, 13B’s Research Group, I3Bs, Research Institute on Biomaterials, Biodegradables and Biomimetics, University of Minho, Portugal
Email: apmarques@i3bs.uminho.pt

Alberto Piaggesi, Department of Endocrinology and Metabolism, University of Pisa, Italy
Email: alberto.piaggesi@med.unipi.it

Symposium Summary
European Wound Management Association (EWMA) strives to be the organisation that citizens, patients, professionals, Governments, Health Services and educational institutes come to for advice, expertise and opinion in Europe, contributing to improve wound patients’ quality of life. Promoting patients’ quality of life is the common and ultimate goal of tissue engineering, and the vision that has been pursued by its community within TERMIS. This symposium aims to close the gap between these organizations by promoting awareness and advocating the need for a high level of interaction between academic scientists, clinicians and industry dedicated to wound healing and management. Active clinical and academic researcher members of TERMIS and/or EWMA will set the discussion ground on the wound healing clinical needs and on how these are being tackled by ongoing research on tissue engineering and regenerative medicine field. Future prospects will be discussed to promote a multidisciplinary approach in the management and treatment of wounds as well as the involvement of main decision makers. Ultimately, this symposium intends to be the first forum of discussion, between two key organizations, on the future of wound healing and management in Europe, and on the measures to be taken to promote an active collaboration between all the relevant players to develop and implement adequate therapies.
Curriculum Vitae

Awardees

Liesbet Geris is Collen-Francqui Research professor in Biomechanics and Computational Tissue Engineering at the University of Liège and KU Leuven in Belgium. Her research focusses on the development of in silico and in vitro models of skeletal tissue engineering processes. The in silico models range from machine learning and bioinformatics models to mechanistic multi-scale and multi-physics models. Liesbet is scientific coordinator of Prometheus, the Leuven R&D platform for skeletal Tissue Engineering (+/-60 researchers and clinicians). She has been awarded an ERC starting grant and an ERC consolidator grant to finance her research and has received a number of young investigator and research awards. She is a strong advocate for in silico (regenerative) medicine and is the current executive director of the Virtual Physiological Human Institute. She is member of the Tissue Engineering and Regenerative Medicine Society strategic alliance committee and one of the co-chairs of the 2021 TERMIS world conference that will be hosted in Maastricht (The Netherlands).
Rui L Reis, PhD, DSc, Hon. Causa MD, Hon Causa PhD, FBSE, FTERM, member of NAE, FAIMBE, FEAMBES, was born in 1967 in Porto, Portugal. He is the Vice-President for Research and Innovation of University of Minho, Portugal, Director of the 3B’s Research Group - member of the I3Bs – Institute for Biomaterials, Biodegradables and Biomimetics, and Director of the ICVS/3B’s Associate Laboratory, both of UMinho. He is also the CEO of the European Institute of Excellence on Tissue Engineering and Regenerative Medicine, the Coordinator of the Discoveries Centre for Regenerative and Precision Medicine, the Global Past-President of the Tissue Engineering and Regenerative Medicine International Society (TERMIS) and the Editor-in-chief of the Journal of Tissue Engineering and Regenerative Medicine. He is a recognized World expert in the TERM and biomaterials fields, that has edited several books and has more 1185 published works listed on ISI Web of Knowledge with an h index of 84 (1045 works and h=90 in Scopus and 1850 and h=106 in Google Scholar), being also an inventor of around 70 patents. Based on those he co-funded several companies that raised important private investments. According to Google Scholar his work has been cited more than 46500 times. He has been awarded many important international prizes, including among several others different innovation awards, the Jean Leray and George Winter Awards (ESB), the Clemson Award (SFB) and TERMIS-EU Awards for contributions to the literature, and recently (2018) the UNESCO- International Life Sciences Award and the IET A. F. Harvey Engineering Research Prize. He is the PI of projects with a budget totalizing more than 50 million Euros.
David F Williams has had 50 years-experience in biomaterials, medical device and tissue engineering, mostly at the University of Liverpool, UK. He has published over 35 books and 430 papers: his latest book, Essential Biomaterials Science, was published by Cambridge University Press in June 2014. He was Editor-in-Chief of *Biomaterials*, the world’s leading journal in this field between 2000 and 2014. He has received major awards from the US and European societies of biomaterials. Professor Williams left the University of Liverpool, UK, in 2007, where he had been Director of the UK Centre for Tissue Engineering and Pro Vice Chancellor of the University. He is currently Professor at Wake Forest Institute of Regenerative Medicine, North Carolina. In South Africa, he has formed a company that will produce low cost, high technology medical devices that can be used with minimally invasive procedures to treat young adults in sub-Saharan Africa, who are suffering from rheumatic heart disease but currently have no therapies available to them.
Plenary

Antonios G Mikos is the Louis Calder Professor of Bioengineering and Chemical and Biomolecular Engineering at Rice University. His research focuses on the synthesis, processing, and evaluation of new biomaterials for use as scaffolds for tissue engineering, as carriers for controlled drug delivery, as non-viral vectors for gene therapy, and as platforms for modeling disease. His work has led to the development of novel orthopaedic, dental, cardiovascular, neurologic, and ophthalmologic biomaterials. He is the author of over 600 publications and the inventor of 29 patents. Mikos is a Member of the National Academy of Engineering, the National Academy of Medicine, the National Academy of Inventors, and the Academy of Athens. He has been recognized by various awards including the Lifetime Achievement Award of the Tissue Engineering and Regenerative Medicine International Society-Americas, the Founders Award of the Society For Biomaterials, the Robert A. Pritzker Distinguished Lecturer Award of the Biomedical Engineering Society, and the Marshall R. Urist Award for Excellence in Tissue Regeneration Research of the Orthopaedic Research Society. He is a founding editor and editor-in-chief of the journal Tissue Engineering, and Past-President of the Tissue Engineering and Regenerative Medicine International Society-Americas and the Society For Biomaterials.
Manuela E Gomes graduated in Metallurgical and Materials Engineering from the University of Porto, obtained the MSc in Polymer Engineering, Univ. of Minho in cooperation with the company Isotis, Bilthoven (Holland) and the PhD in Materials Science and Engineering – Tissue Engineering/Hybrid Materials in collaboration with the Rice University (USA). She is a founder member of the 3B’s Research Group of the University of Minho and was one of the Vice-Directors of the Group from 2011-18. Presently she is Associate Professor and President of the Research Institute on Biomaterials, Biodegradables and Biomimetics (I3Bs) of the University of Minho, Portugal. Manuela Gomes research interests have focused on bone, cartilage and more recently, tendon tissue engineering strategies, namely in the development of scaffold materials based on biodegradable natural origin polymers, stem cells sourcing and differentiation (using biochemical and physical methods); In recent years, her research has been focusing on the use of platelets based biomaterials and magnetic tissue engineering approaches for modulating the functionality/regenerative potential of tendon/ligament tissue engineered constructs. Manuela has been part of numerous European and national/regional projects as PI/member, including for example, the European Network of Excellence EXPERTTISSUES, which originated the European Institute of Excellence in Tissue Engineering (EXPERTTISSUES EEIG), leaded by 3B’s. More recently, she has been involved in the EC funded project “THE DISCOVERIS CTR” (H2020-WIDESPREAD-01-2016-2017-Teaming), which aims at implementing a new Center of Excellence in Regenerative and Precision Medicine at the University of Minho (in collaboration with the major Portuguese universities and the University College of London). She was awarded a Consolidator Grant from the European Research Council (ERC CoG) to develop magnetically assisted tissue engineering technologies for tendon regeneration that started in May 2018 and with a EC funded Twinning Project – Achilles: Overcoming specific weaknesses in tendon biology to design advanced regenerative therapies”, in collaboration with NUI Galway (Ireland), Regensburg University (Germany) and the Mayo Clinic (USA). Manuela E. Gomes is editor 2 books (presently also Assistant Editor of the Tissue Engineering Encyclopedia, to be published by Elsevier in 2019) and author of 38 book chapters, 180 full papers published in international refereed journals, and more than 300 communications in international Conferences. She has been invited to give 40 lectures in international conferences and advanced schools. She is also co-author of 7 patents (national/international). Manuela E. Gomes is an active member of several International Scientific Organizations, but she has been particularly involved in the Tissue Engineering and Regenerative Medicine International Society (TERMIS). She has received several awards, including the 2013 tissue engineering and Regenerative Medicine International Society – European Chapter (TERMIS-EU) Young Investigator Award. More info on: https://3bs.uminho.pt/users/megomes
Nektarios Tavernarakis is the Chairman of the Board of Directors at the Foundation for Research and Technology-Hellas (FORTH), Research Director at the Institute of Molecular Biology and Biotechnology (IMBB), and Professor of Molecular Systems Biology at the Medical School of the University of Crete, in Heraklion, Greece. He is the Director of the Graduate Program on BioInformatics at the Medical School of the University of Crete, and is also heading the Neurogenetics and Ageing laboratory of IMBB. He is an elected member of the Scientific Council of the European Research Council (ERC), the European Molecular Biology Organization (EMBO), the European Academy of Sciences and Arts, and Academia Europaea. He has also served as the Director of the Institute of Molecular Biology and Biotechnology. He earned his Ph.D. degree at the University of Crete, and trained as a postdoctoral researcher at Rutgers University in New Jersey, USA. His research focuses on the molecular mechanisms of necrotic cell death and neurodegeneration, the interplay between cellular metabolism and ageing, the mechanisms of sensory transduction and integration by the nervous system, and the development of novel genetic tools for biomedical research. He has received several notable scientific prizes, including two ERC Advanced Investigator Grants, and an innovation-supporting ERC Proof of Concept Grant. He is also the recipient of the EMBO Young Investigator award, the Alexander von Humboldt Foundation, Friedrich Wilhelm Bessel research award, the Bodossaki Foundation Scientific Prize for Medicine and Biology, the Empeirikeion Foundation Academic Excellence Prize, the FORTH Research Excellence award, the BioMedical Research Award of the Academy of Athens, the Galien Scientific Research Award, the Helmholtz International Fellow Award, the International Human Frontier in Science Program Organization long-term Postdoctoral Fellowship, and the Academic Achievement Award of the Hellenic University Club of New York.
Seppo Yla-Herttuala is a world leader in cardiovascular gene therapy for atherosclerosis and ischemic diseases. His team was the first to use adenovirus-mediated gene transfer to human arteries already in 1995. Since then, he has conducted eight phase 1-3 clinical trials in cardiovascular gene therapy. He is also the originator of the concept of epigenetherapy. His group has been widely recognized for basic biology, translational and epigenetic research of the vascular endothelial growth factors, especially focusing on the new members of the VEGF family. Previously he worked with oxidized LDL and atherosclerosis and was the first to show that OxLDL exists in human atherosclerotic lesions. His list of publications includes over 500 scientific articles.
Wim E Hennink obtained his Ph.D. degree in 1985 at the Twente University of Technology on a thesis with a biomaterials research topic. From 1985 until 1992 he had different positions in the industry. In 1992 he was appointed as professor at the Faculty of Pharmacy of the University of Utrecht. From 1996 on he is head of the Pharmaceutics division. At present he is the head of the Department of Pharmaceutical Sciences, Utrecht University. His main research interests are in the field of polymeric drug delivery systems. He has published over 580 papers and book chapters and is the inventor of 20 patents.
Invited

Abhay Pandit is an Established Professor of Biomaterials at the National University of Ireland, Galway. He is the Scientific Director of the Centre for Research in Medical Devices (CÚRAM), a multi-disciplinary academic-industry-clinician translational research centre funded by Science Foundation Ireland (E49M). Prof. Pandit’s research integrates material science and biological paradigms in developing solutions for chronic diseases. Prof Pandit has developed next generation reservoir delivery vehicles with high payload capacity, programmable degradation profiles and inbuilt gradients of physical, chemotropic and protective cues which facilitate spatiotemporal localised sustained delivery of multiple biomolecules to target injury mechanisms at the molecular and cellular levels. These biomaterial platforms have been validated to act as inductive templates for constructive remodelling and as templates for the induction of de novo functional, site-appropriate, tissue formation. These platforms have been developed for neural, musculoskeletal and cardiovascular clinical targets with numerous other targets currently under development. Prof. Pandit has received numerous awards and distinctions. He was inducted as an International Fellow in Biomaterials Science and Engineering by the International Union of Societies for Biomaterials Science and Engineering and elected as a Fellow of the Tissue Engineering and Regenerative International Society. He was also elected to the American Institute of Medical and Biological Engineering (AIMBE) College of Fellows in recognition of his outstanding contributions to establishing a national centre which will develop transformative device-based solutions to treat global chronic diseases. He has been an elected member on the Council for both the Tissue Engineering and Regenerative Medicine International Society and European Society for Biomaterials Society. He has hosted TERMIS-EU meeting in 2010 and ESB in 2011--both for the very first time in Ireland. Prof Pandit has published more than 250 papers in peer-reviewed journals, filed numerous patent applications and has licensed four technologies to medical device companies. Prof Pandit is an Executive Editorial Board of the Tissue Engineering journal, an Associate Editor of the Biomaterials journal. He has co-ordinated four EU grants to date and has generated research contracts from industry and government funding agencies totaling €90M.
Akon Higuchi is a Chair Professor in National Central University. He received his Ph.D. in Tokyo Institute of Technology in 1985. Higuchi was a Professor in Seikei University (Tokyo, Japan) from 1993 to 2007. He received Sofue Memorial Award from Society of Fiber Science, Japan, Seikei Academic Award from Seikei Alumni Association, Fellow of Royal Society of Chemistry (UK), Fellow of Taiwan Institute of Chemical Engineers (Taiwan), and Fellow of American Institute for Medical and Biological Engineering (USA). Dr. Higuchi is an Editorial Board of Laboratory Investigation (Nature Springer, Impact Factor=4.3), Advisory Board of Journal of Materials Chemistry B (RSC, Impact Factor=4.8) and Editorial Board of Tissue Engineering and Regenerative Medicine (Springer Nature, Impact factor=1.169). Dr. Higuchi served as a session chair or a session organizer at a number of International Conference [e.g., Termis-AM2017, Termis-EU2017, Termis-AP2016, Pacifichem 2015, IUMRS-ICA2014, ISOMRM2014, etc.]. Five articles published by Dr. Higuchi are selected as Highly Cited Paper in Web of Science. Dr. Higuchi published 6 high impact factor articles; 3 articles in Chemical Reviews (Impact Factor=52.6) and 3 articles in Progress in Polymer Science (Impact Factor=24.6) as first author and corresponding author since 2011. Dr. Higuchi’s research focuses on the design, preparation and evaluation of new biomaterials and membranes for purification, culture, and differentiation of stem cells in biomedical applications. He has developed a membrane filtration method for purification of stem cells from umbilical cord blood and fat tissues. He also developed cell culture biomaterials grafted with nanosegments for xeno-free culture of human pluripotent stem cells including human embryonic stem cells and induced pluripotent stem cells as well as hematopoietic stem cells and adipose-derived stem cells.
Alberto Piaggesi is currently the director of the Diabetic Foot Unit at the Department of Medicine, Azienda Ospedaliero-Universitaria Pisana, Italy and a Professor at the University of Pisa Medical School of the same country. As a medical doctor, he has demonstrated expertise in tissue repair, diabetic foot surgery and peripheral neuropathy and macroangiopathy. Professor Piaggesi performed, as first operator, more than 3000 diabetic foot surgical operations, developing innovative techniques. He is the author of more than 100 publications on national and international papers, and three monographies in Italian on neuropathy and lower limbs complications. Furthermore, he is Member of the “Board of Directors” of the Diabetic Foot Study Group of European Association for the Study of Diabetes, of the Società Italiana di Diabetologia, where he coordinates the diabetic foot study group, co-founded GISED and is part of study groups on neuropathy and education. He is also a member of the Associazione Medici Diabetologi, the American Diabetes Association and of the European Tissue Repair Society. He is a Past-Chairman of the Gruppo di Studio “Piede Diabetico” della Società Italiana di Diabetologia and scientific recorder and president elect of the European Wound Management Association (EWMA).
Alberto Saiani, PhD, FRSC, MInstP is Professor of Molecular Materials at the University of Manchester, School of Materials & Manchester Institute of Biotechnology, UK. He graduated and did his PhD in polymer physics at the University Louis Pasteur, Strasbourg, France. Following his PhD he held a number of post-doctoral positions in Belgium, Japan and the UK. In 2000 he was appointed lecturer at the University Blaise Pascal, Clermont-Ferrand, France before joining in 2002 the University of Manchester where he established the Polymers & Peptides Research Group (www.polymersandpeptides.co.uk). His research work spans a wide area of experimental polymer and biopolymer science and focuses on understanding the chemical architecture - thermodynamic - structure - physical property correlations in complex polymeric systems. His work encompasses a variety of synthetic and biological polymeric materials including polyurethanes and polyureas elastomers; and protein and peptide hydrogels (www.polymersandpeptides.co.uk). In 2013 he was awarded a 5-year research fellowship by the Engineering and Physical Science Research Council (EPSRC, UK) to pursue his work on self-assembled peptide biomaterials and in 2014 this work led him to co-found Manchester BIOGEL (www.manchesterbiogel.com), which develops and commercialises advanced gel-based combination products for the life science and biomedical sector. In 2016 he was elected fellow of the Royal Society of Chemistry.
Aleksandr Ovsianikov is currently an Associate Professor at the TU Wien (Vienna, Austria) and a member of the Austrian Cluster for Tissue Regeneration. His research is dealing with the use of additive manufacturing technologies for tissue engineering and regenerative medicine. Dr. Ovsianikov has background in laser physics and material processing with femtosecond lasers. A particular focus his current research is establishing multiphoton lithography in the domain of biofabrication for engineering of biomimetic 3D cell culture matrices and realization of novel tissue engineering scaffolds. Dr. Ovsianikov was awarded a prestigious Starting Grant in 2012 and a Consolidator Grant in 2017 from the European Research Council (ERC) for projects aimed at these topics. His research interests include high-resolution 3D printing, laser-induced photo-chemistry, development of biomaterials for additive manufacturing and bioprinting. Together with Prof. Mironov and Prof. Yoo he is an editor of a living book project “3D Printing and Biofabrication” published by Springer in cooperation with Tissue Engineering and Regenerative Medicine International Society (TERMIS).
Alessandra Balduini, MD, got her Medical Degree and Board of Clinical Biochemistry at the University of Pavia, Italy. After obtaining her Medical Degree she spent three years at the University of Indiana, Indianapolis, USA working, as post-doc, in the laboratory of Hal Broxmeyer, one of the pioneers of cord blood transplantation. Before creating her research group in 2007, she was a staff physician in the laboratory of Clinical Biochemistry, IRCCS San Matteo Foundation, and University of Pavia, Italy. In 2005-2006 she was Visiting Professor at Dana Farber Cancer Institute at Harvard Medical School. Since 2007 she has led a research group that is based in two different academic institutions: the Department of Molecular Medicine - University of Pavia, Italy and the Department of Biomedical Engineering - Tufts University, Boston, USA. The goal is to establish a cross-sectional program that integrates biological with bioengineering approaches to the study of haematopoiesis and bone marrow environment. Her research focuses on how the different components of the bone marrow microenvironment regulate platelet production. In 2011 she developed the groundwork for modeling human bone marrow by bioengineering a new 3D model made of porous silk that fully recreates the physiology of the living bone marrow niche environment. This system, completely redesigned in 2015 and 2017, is capable of successfully generating functional platelets ex vivo, offering new opportunities for producing blood components for clinical applications.
Alexandra P Marques has a PhD on Materials Science and Technology - Biomaterials from the University of Minho, Portugal and in cooperation with the University of Liverpool, UK. She is a Founder, Deputy-Director and Principal Investigator of the 3B’s Research Group, University of Minho, Portugal. She is also Member of the Governing Board of the PT Government Associate Laboratory ICVS/3B’s. She is Associate Editor of the Journal of Tissue Engineering and Regenerative Medicine (TERM), John Wiley & Sons - Blackwell, launched in 2007, of which was also Assistant Editor (2009-2016). She is member of several International Scientific Organizations and has been actively participating in the activities of TERMIS, European Wound management Association (Elected Council Member from July 2018) and the Portuguese Society for Stem Cells and Cellular Therapy (SPCE-TC, founder member and coordinator of the Section Cell Therapies and Tissue Engineering -2011/2012). After receiving Starting and Development Career Grants from the Portuguese Science Foundation, she was also awarded a Consolidator Grant from the European Research Council (ERC-2016-COG). This adds to the different National and International projects in which she was core member (FP6 EXPERTISSUES Network of Excellence, ERC AdG ComplexiTE, M-ERA.NET Bioteraface) or that she has been coordinating such as those approved under the M-ERA.NET 2016 and H2020-TWINN-2015 actions. She edited 2 books, and is author of 98 peer-reviewed publications, 18 book chapters, 96 Indexed conference abstracts and proceedings and more than 220 communications in major conferences of the field. She is co-inventor of 13 patents (5 families).
Alicia El Haj, FREng, FRSB, FEAMBES, Interdisciplinary Professor of Cell Engineering, joined the Healthcare Technology Institute in the Institute of Translational Medicine at Birmingham University, UK in September 2018. Previously, she has been the founding Director of the Institute of Science & Technology in Medicine at Keele University Medical School. She is a leading figure in Bioengineering and Regenerative Medicine and has been involved in bringing together interdisciplinary groups within biomedicine, physical sciences and engineering interested in aspects of cell and tissue engineering and regenerative medicine to move innovative new cell based therapies to the clinic. She has published over 200 publications in novel tissue engineering approaches such as biomechanics, bioreactors, and imaging systems for the delivery of cell therapies to the clinic with funding from EPSRC, MRC, BBSRC, AR UK and EU Framework in the UK. She is also Director of a spin out company MICA Biosystems, Ltd involved in translating cell biomechanical control systems into clinical use. She is Deputy Director of the MRC UKRMP Regen Med Hub and has been a Research Director of an EPSRC Doctoral Training Centre in Regenerative Medicine, and a co-director of the EPSRC Centre for Innovative Manufacturing Centre in Regenerative Medicine as well as a partner in multiple EU programmes. Prof. El Haj is president of the UK Bioengineering Society and ex-Chair of the European Council for the Tissue Engineering & Regenerative Medicine International Society (TERMIS). She was awarded with a Royal Society Merit Award in 2014 and is a Fellow of the Royal Academy of Engineering in the UK. In March 2015, she was awarded the MRC Suffrage Award for her role in leading women in STEM.
**Aline Miller**, PhD, is Chief Executive Officer and Co-Founder of Manchester BIOGEL, a company specialising in providing engineered, self-assembling peptide hydrogels for 3D cell culture, 3D bioprinting and incorporation within medical devices. She currently oversees all aspects of the business from product production and development, to marketing and sales, to ensure our customers receive the very best product and service. Aline is also Professor of Biomolecular Engineering in the School of Chemical Engineering at the University of Manchester where she has won several awards, including The Royal Society of Chemistry MacroGroup UK Young Researchers Medal, The Institute of Physics, Polymer Physics Group Young Researchers Lecture Award and the Philip Leverhulme Prize for Engineering for her work on self-assembling peptide materials. In this area she has published over 100 refereed papers, authored 5 patents and has won > £8M from research councils, EU, charities and industry to support her research group.
Alvaro Mata is Professor in Biomaterials and Biomedical Engineering in the School of Engineering and Materials Science at Queen Mary University of London (QMUL). He holds a Bachelor's Degree from the University of Kansas, a Master's Degree from the University of Strathclyde, and a Doctor of Engineering Degree from Cleveland State University working with Prof. Shuvo Roy. He conducted his postdoctoral training with Prof. Samuel Stupp at Northwestern University working on self-assembling materials. From 2008-2013 he was Head of the Nanotechnology Platform at Parc Scientific Barcelona in Spain and from 2014-2017 the Director of the Institute of Bioengineering at QMUL. He holds seven patents or patent applications; publications in journals including Science, Nature Chemistry, and Nature Materials; and awards such as the Baxter Early Career Award in 2006, Ramon y Cajal Award in 2010, an ERC Starting Grant in 2012, and a Frontiers Innovator Award from the Wellcome Trust in 2015. He is a member of the Board of the Biomedical Engineering Association, Editorial Board of several leading biomaterial journals, and the UK Regenerative Medicine Platform – Smart Materials Hub. More information can be found at: www.matabioengineering.com/, https://twitter.com/mata_lab.
Amaia Cipitria, PhD, got her Ph.D. in Materials Science and Metallurgy at the University of Cambridge, UK, in 2008. She worked as a postdoctoral researcher at Queensland University of Technology, Brisbane, Australia, and at the Charité University Hospital Berlin, Germany. In 2011 she became a principal investigator at the Charité University Hospital Berlin, investigating the effect of biomaterial physical properties, such as stiffness, geometry or degradation properties, on cell response and in-vivo bone regeneration, using small and large animal models. She applies advanced materials characterization techniques to investigate tissue hierarchical structure at different length scales and its biological function. In 2017 she moved to the Max Planck Institute of Colloids and Interfaces, Potsdam, Germany, as an Emmy Noether group leader. Her current research is focused on how biophysical mechanisms regulate cell-matrix interaction in tissue regeneration, cancer dormancy and bone metastasis.
Ana Marina Ferreira-Duarte has completed her PhD at Politecnico di Torino (Italy) in 2013. Following that, she joined EC FP7 RESTORATION project and the Arthritis Research UK (ARUK) Tissue Engineering Centre at Newcastle University as Research Associate to optimise the bio-functionalisation of 3D printed scaffolds for regenerative medicine. In late 2015, she became a Lecturer in Bioengineering within the School of Engineering at Newcastle University. Her research is centred in the design of biomaterials, bioinks for 3D-printing and bio fabrication of hybrid constructs with advanced functional properties for regenerative medicine applications. She has published over 27 papers in international peer-reviewed journals (with over 450 citations) and filed one patent on biodegradable bone cements (WO2012176224 A1). In the last few years, she has been co-investigator in projects (worth more than £300k) related to (1) the bio-fabrication of constructs and microtissues for disease modelling and regenerative medicine and (2) the development of automated platforms for osteoarthritis drug screening. Ana’s exiting vision pursues to advance in materials for the fabrication of safe, reliable and cost effective patient-specific therapies for the regeneration of damaged tissues.
Ana Paula Pêgo, PhD, got her Ph.D. in Polymer Chemistry and Biomaterials from the University of Twente, the Netherlands, in 2002. In 2003 she became a researcher at INEB where she is a Principal Investigator since 2012. By using nanomedicine strategies her group – the nanoBiomaterials for Targeted Therapies (nBTT) Group - aims at providing in situ and in a targeted manner the required signals to promote nervous tissue regeneration. The research on new biomaterials for application in neurosciences includes the development of new polymers for the design of alternative vectors to viruses for efficient nucleic acid delivery and preparation of nerve grafts for spinal cord injury treatment. Societal and ethical issues that concern Regenerative Medicine and NanoMedicine are also a topic in which Ana Pêgo is involved. She has been appointed the Scientific Director of the Bioimaging Centre for Biomaterials and Regenerative Therapies of INEB and she is an Invited Associate Professor at the Instituto de Ciências Biomédicas Abel Salazar (ICBAS) and at the Faculty of Engineering (FEUP) of the University of Porto. Since 2015, Dr. Ana Paula Pego is a member elected from the European Society for Biomaterials (ESB), currently being the ESB Secretary. She is Associate Editor of Biomaterials.
Andrea Banfi, M.D., directs the group of Cell and Gene Therapy at University Hospital of Basel (Switzerland), in the Department of Biomedicine of Basel University. He received several awards from Swiss, European and US scientific societies, is author of over 50 peer-reviewed publications, which have been cited about 2’500 times, inventor on 2 international patents, and he serves on two journal Editorial Boards and on the Council of two international cardiovascular societies. His research focuses on the basic principles governing the growth of blood vessels and translating these concepts into novel regenerative medicine approaches to: 1) treat ischemic diseases (peripheral and cardiac) and 2) improve the in vivo vascularization of clinical-size tissue engineered grafts. Over the last decade his research group has developed a unique expertise bridging basic vascular biology and biomaterial-based approaches to control vascular growth for therapeutic purposes, requiring close integration between biological, clinical and biomaterial competences in multi-disciplinary approaches.
Andrea Remuzzi graduated in Biomedical Engineering, at the Polytechnic of Milan in 1979. From 1982 to 1984 he was visiting scientist at M.I.T. (Fluid Mechanical Laboratory and Harvard Medical School, Brigham and Womens’ Hospital). From 1984 to 1999 he was a research investigator at the Mario Negri Institute for Pharmacological Research in Milan and Bergamo. From the 1999 he is the Head of the Department of Bioengineering of the “Mario Negri” Institute in Bergamo, Italy. During the period 1998-2007 he was also contract professor at the Polytechnic University of Milan, Department of Bioengineering. From 2007 he is a Professor of Biomedical Engineering at the University of Bergamo. His research activity resulted in over 172 publications on international scientific journals on several topics of bioengineering, biophysics, renal and vascular pathophysiology. He has conducted educational endeavours, organizing and managing several events, teaching activities at high educational level (University) and as tutor of PhD students. Main areas of interest of Andrea Remuzzi range from engineering to pathophysiology in the field of transport phenomena in biological systems (filtration of macromolecules, interaction between circulating cells and vascular wall, characterization of the motion of blood in large vessels and in the microcirculation), effect of shear stress on endothelial cell function, morphometrical analysis of the ultrastructure of the glomerular capillary, computational fluid dynamics in large arteries and in the microcirculation, pancreatic cell transplantation in experimental models of insulin dependent diabetes and tissue engineering. He has been head of ten research projects at national and European level.
Andreas Kaasi is Founder of Eva Scientific, a tissue engineering and bioreactors company founded in 2015. Benefiting from a strong vantage point at the interface of Academia and Industry, he has held several positions in each sector over the last decade. He is B.Sc. (2006) and M.Sc. (2008), both in Biomedical Engineering and awarded by the Technical University of Denmark in conjunction with its partner institution, the University of Copenhagen. Exchange student at the University of Strathclyde from 2005 to 2006, affiliated with the departments of Bioengineering, Mathematics and Pharmacology. Exchange student at the University of São Paulo from 2007 to 2008, affiliated with the Heart Institute - InCor - to the Nuclear and Energy Research Institute - IPEN - and to the graduate program in Bioengineering at the University of São Paulo in São Carlos. Visiting Researcher at the University of Leeds working on a cardiovascular bioreactor project (2009). From 2010 to 2013, he worked as principal scientist in the pharmaceutical industry in Cambridge, England, on various projects including several bioreactors and a project for large-scale production of collagen-based tissues, with applications in In Vitro Testing and Regenerative Medicine. He has experience in the areas of bioreactors, tissue engineering, regenerative medicine, cardiovascular surgery, ophthalmology, biomaterials and veterinary applications. Between 2014 and 2016, he was affiliated with the National Institute of Science and Technology in Biofabrication-BIOFABRIS, a multi-centric institute with headquarters at UNICAMP-Faculty of Chemical Engineering, being responsible for the introduction and implementation of new research programs in the areas of bioreactors, tissue engineering and regenerative medicine. He was invited to join the Albert Einstein Hospital as a Visiting Researcher in 2015, where he was engaged in different bioengineering projects, including porcine kidney decellularization activities. In 2016, the affiliation with HIAE was ended to allow for a 100% dedication to R&D and commercial activities at Eva Scientific Ltd. In 2018, he resumed ties with Academia, this time with Latin America’s largest philanthropic hospital, Santa Casa de São Paulo, occupying the position of Research Bioengineer. He is reviewer for the Journal of Tissue Engineering and Regenerative Medicine (Wiley) since 2010, and a member of TERMIS (2008), SLABO (2015) and ISBF (2016).
Andreas Traweger currently is a Research Professor for Regenerative Biology at the Paracelsus Medical University in Salzburg, Austria. He received his PhD in Genetics from the University of Salzburg and completed his post-doctoral training at the Samuel Lunenfeld Research Institute in Toronto, Canada under the guidance of Prof. Tony Pawson. He was then R&D Manager at Baxter (Vienna) before moving back to Salzburg to join the Paracelsus Medical University. He published numerous peer-reviewed manuscripts, including articles in Cell, PNAS, and Scientific Reports and serves as ad hoc reviewer for a large number of biomedical journals. His research is interdisciplinary in nature, focusing on both high quality fundamental science and translation for human health. His research interests lie in promoting our understanding of tendon biology in general and to devise novel strategies in tendon and bone regeneration. Since 2018 he is also CSO of Celericon Therapeutics GmbH, a biotech startup focusing on the production and use of MSC-derived exosomes to improve tissue regeneration.
Andy Lewis is Vice President Research & Development in the Innovation group within Biocompatibles UK Ltd (a BTG International group company). His career has spanned almost three decades across small, medium and large enterprises and he currently specialises in the development of advanced biomedical polymer systems, for instance, to enhance the biocompatibility of implants or to modulate delivery of active agents in the body. These technologies have been applied to novel drug-device combination products for use in interventional therapies in the treatment of cardiovascular disease and cancer and have resulted in around a dozen products reaching commercialisation. Andy has generated around 225 peer-reviewed publications (>11,600 citations, H-index 59), 12 book chapters and over 50 patent families/applications in the fields of polymers, biomaterials and drug delivery. He is Professor of Biomaterials & Drug Delivery at the University of Brighton where he currently holds a Royal Society Entrepreneur in Residence Fellowship. He has been awarded the Chapman Medal for distinguished research in the field of biomedical materials, holds a Royal Pharmaceutical Society Excellence in Pharmaceutical Science award and was recipient of the 2017 Macro Group Medal. He is a Fellow of the Royal Society of Chemistry, Institute of Materials Minerals and Mining where he chairs the Biomedical Applications Division and a Fellow of the Academy of Pharmaceutical Sciences. Most recently he was honored with admission to Fellow of the Royal Academy of Engineering for his contributions to Biomedical Engineering.
Anna Lange Consiglio, born in Piacenza on July 3rd, 1962, is associated professor and laboratory manager of Reproduction Laboratory at the Department of Veterinary Medicine of the University of Milano (Italy). He graduated in Animal Science (110 magna cum laude) in 1986 and in the same year obtained a graduates position at the Faculty of Veterinary Medicine of the University of Milano. From 1986 up to date, Prof Anna Lange Consiglio has published 71 peer reviewed articles in the field of the Biology of Reproduction and 117 congress proceedings. All these papers aim to clarify the connections occurring between male infertility and abnormal sperm chromatin packaging in mammals, studying the role of oxidative stress and apoptosis in influencing nuclear DNA damage in mature sperms. Many other papers regard biotechnology of reproduction in the bovine species including male and female gametes cryopreservation. Since 2008, Prof. Anna Lange Consiglio is responsible for the isolation, culture, expansion and characterization of mesenchymal cells isolated from umbilical cord and amnion in equine, bovine, canine, swine and feline species with the prospect of creating a stem cell bank in order to use these cells in regenerative medicine in the veterinary field. Actually, Prof Anna Lange Consiglio is studying the paracrine mechanism of stem cell action focusing on microvesicles effect on stresses target cells.
Anna Blocki graduated with a BSc degree in Molecular Biology from the University of Applied Sciences of Gelsenkirchen, Germany, in the top 5% of her cohort in 2008. Subsequently she joined the group of Prof. Michael Raghunath within the Department of Bioengineering to pursue her PhD studies on “Peripheral blood: a simple cell source for the generation of angiogenic progenitors from monocytes”. Her work on Blood Derived Angiogenic Cells (BDACs) and extracellular matrix (ECM) engineering inspired her to investigate the therapeutic potential of the developed technologies in preclinical studies. This was realized during her first postdoctoral appointment at the Singapore Bioimaging Consortium (SBIC) at the Agency for Science Technology and Research (A*STAR) from December 2012 to April 2015. Following that, she was able to secure a competitive postdoctoral fellowship from the Charité Universitätsklinikum zu Berlin that allowed her to work towards ECM-mimicking biomaterials and their potential clinical application. Since February 2018 she has joined the Institute for Tissue Engineering and Regenerative Medicine and the School of Biomedical Sciences at the Chinese University of Hong Kong as an assistant professor. Her newly established laboratory focuses on in vitro ECM-based biomaterials, deciphering the ECM and on cell-based therapies.
Anna Mitraki is Professor at the Department of Materials Science and Technology at the University of Crete and Affiliated Research Scientist at IESL-FORTH (since September 2004). She received her BS in Chemistry from the University of Thessaloniki, Greece, 1981 and her PhD in Biochemistry from the Université Paris-Sud, Orsay, France in 1986 (for work on enzyme folding, assembly and aggregation with Professor Jeannine Yon-Kahn). She subsequently was a post-doctoral associate at the Massachusetts Institute of Technology, Cambridge, MA, U.S.A. (1987-1991) and then a Research Scientist (1991-1994) (work on folding and assembly of fibrous phage proteins with Professor Jonathan King). She received her Habilitation from the Université Joseph Fourier, Grenoble, France, in 2003 for work on structure, folding and assembly of beta-structured fibrous proteins and their self-assembling peptides. She worked as Research Scientist at the Institut de Biologie Structurale in Grenoble, France (French National Research Center) from 1995 to 2004. From 2004 to 2014 she was Associate Professor at the Materials Science and Technology Department at the University of Crete; she was promoted to Professor in 2014. Anna Mitraki has been working for a more than 30 years on the folding, assembly and structure of natural fibrous proteins. She got interested in using these proteins as models for the design of new fibrous materials. Her current research interests include: protein folding and assembly; protein engineering and production; design and study of fibrous biomaterials; self-assembling protein and peptide materials. She is particularly interested in translating fundamental structural knowledge from natural fibrous proteins into concrete integration strategies and applications in the area of fibrous bio-nano-materials. She especially focuses on the use of amyloid peptide materials as technological objects and their integration in innovative applications.
Anne Camus, PhD, studied Genetics and Embryology at University Paris XI, followed by a PhD with Charles Babinet, at the Pasteur Institute, Paris, France. In 1997, she carried out postdoctoral training with Patrick Tam at the Children’s Medical Research Institute, Sydney, Australia. In 2000, she joined Jérôme Collignon in the Jacques Monod Institute, Paris. In 2001, she was appointed as senior scientist at C.N.R.S. She has a long-standing interest in deciphering basic mechanisms that regulate cell fates during embryogenesis and in stem cells differentiation studies. In 2013, she joined in Nantes, France, the Regenerative medicine and skeleton research lab -INSERM UMR1229-RMeS- headed by Jerome Guicheux, as the "Stem Cells and Axial Skeleton Development" group leader. Her current research focuses on studying the cellular and molecular mechanisms of axial skeleton development using genetic tools in the mouse model and human stem cells tissue engineering for intervertebral disc (IVD) regenerative medicine. She is developing systems biology approaches to identify gene networks and signaling pathways associated with IVD differentiation, growth and degeneration. Anne Camus is coordinating the “DevStem” scientific cluster at Nantes University to promote collaboration between researchers interested in stem cells, development and reprogramming. This initiative aims to strengthen the developmental and stem cell biology field in the region and supports the recent French Society of Stem Cells Research (FSSCR) initiative to coordinate the national research efforts and increase the visibility of the French stem cell community.
Anne des Rieux is an Associate Professor at the Université Catholique de Louvain (UCLouvain, Belgium) and is part of the Advanced Drug Delivery and Biomaterials unit (Louvain Drug Research Institute). She got her PhD in Pharmaceutical Sciences from the Université Catholique de Louvain in 2006 on oral drug delivery. Then, she spent 1 year as a postdoc as a BAEF fellow at the Northwestern University in Chicago (2007) in the Shea Lab where she worked on drug delivery strategies for spinal cord repair. She became a principal investigator (FNRS Research Associate) in 2011. She then set up a research group within the Advanced Drug Delivery and Biomaterials unit focused on drug and stem cell delivery for the central nervous system repair.
Anthal Smits obtained his Ph.D. in Biomedical Engineering from the Eindhoven University of Technology, Eindhoven, the Netherlands, in 2014. After a two-year stay in industry at LifeTec Group B.V., he was appointed Assistant Professor at Eindhoven University of Technology in 2016, where he since leads the ImmunoRegeneration Group in the Soft Tissue Engineering and Mechanolobiology division, headed by prof. Carlijn Bouten. His research is dedicated to gaining a mechanistic understanding of the interactions between immune cell behavior, biomaterial design, and biomechanical loads, in conditions of health and disease. Topics of investigation range from the fundamentals of patient-specific macrophage-biomaterial interactions using dynamic in vitro platforms, to the development regenerative scaffolds for heart valve and blood vessel tissue engineering. He is a core member of the Institute for Complex Molecular Systems (ICMS) at Eindhoven University of Technology and an associate member of the Heart Valve Society, among others. In 2016, Dr. Smits was elected to take seat in the Young Investigator Board of Tissue Engineering, Parts A, B, & C. Since 2018, he serves as a board member of Young@Heart (Netherlands Heart Institute, NLHI), which aims to support and secure the future of excellent cardiovascular research in the Netherlands.
Anthony Weiss, PhD, is the McCaughey Chair in Biochemistry, Professor of Biochemistry & Molecular Biotechnology, Leader of the Tissue Engineering & Regenerative Medicine Node at the Charles Perkins Centre, and Professor at the Bosch Institute at the University of Sydney. He is an inventor on forty-three awarded patents, on ten Editorial Boards, Fellow of nine societies and was recently awarded the Order of Australia in the field of biotechnology, as an academic, researcher, author and mentor, and through executive roles with scientific institutions. He has pioneered research into human tropoelastin (the protein building-block that gives tissue its elasticity) and discovered how to assemble it into synthetic elastin biomaterials that accelerate and improve the repair of scars and wounds. This work over two decades has made him the world leader in the field, and his patented biomaterials inventions recently led to one of the largest commercial transactions in Australian healthcare history.
Antonietta R. Silini obtained her Bachelors of Science in Microbiology from the University of Maryland at College Park (USA) and her PhD degree in the discipline of Life Sciences in Milan (Italy) at the Mario Negri Institute for Pharmacological Research, in collaboration with the Open University of London (UK). Her past research interests were focused in cancer biology, and specifically on understanding the cross-talk between tumor and microenvironment in order to identify targets for therapy. Her current recent research interests are now focused on investigating placental stem cells, and their potential therapeutic effects in different diseases, including cancer. Antonietta works at the Centro di Ricerca E. Menni (CREM), Fondazione Poliambulanza-Istituto Ospedaliero, which is internationally recognized for its research and contributions in this field. CREM’s research is focused on investigating the immune modulatory properties of mesenchymal stromal cells isolated from the amniotic membrane, and their role in the inflammatory process during tissue regeneration. Since 2014 Antonietta is a Board Member of the International Placenta Stem Cell Society, and in 2018 she was elected Treasurer of the Society. She is Associate Editor of the book entitled “Placenta: The Tree of Life” (Editor: Ornella Parolini, February 2016), that is dedicated to understanding the human placenta during gestation and especially after birth when it is as a source of tissue and cells with regenerative potential.
António Salgado is a biologist with a PhD in Materials Science and Engineering - Tissue Engineering and Hybrid Materials (2005, University of Minho), and a Habilitation (DSc) in Health Sciences (2018, University of Minho). Currently he is a Principal Investigator at the Life and Health Sciences Research Institute (ICVS) and an Adjunct Associate Professor in the School of Medicine, University of Minho. His research interests are focused on the development of innovative therapies for CNS repair, namely on Spinal Cord Injury and Parkinson’s Disease. His main areas of research are: 1) Development of ECM like hydrogels for the transplantation of Mesenchymal Stem Cells into the injured CNS; 2) Role of the secretome of MSCs in neuroprotection and repair, particularly the establishment of novel therapies based on the sole use of MSCs secretome. His lab has successfully introduced the use of peptide grafted gellum gum based hydrogels for spinal cord injury regenerative medicine. Simultaneously it has also made important contributions for the characterization and use of therapies based on stem cells secretome for CNS repair, particularly in Parkinson’s Disease. Presently he is the coordinator of the Portuguese Network for Spinal Cord Injury Research and director of the Spinal Cord Injury Initiative @ ICVS (SCI CVS). He serves as an Associate Editor for Biomed Research International, Biochimie, BMC Neuroscience and Stem Cells International. He has received several distinctions for his work including the Gulbenkian Award on Cutting Edge Research in Life Sciences, and the Prize Melo e Castro for Spinal Cord Injury Research, awarded by Santa Casa de Misericordia de Lisboa (2013 and 2017).
Aram Saeed, PhD, is Lecturer in Drug Delivery and Tissue Engineering at the School of Pharmacy, University of East Anglia, Norfolk, UK. He holds a PhD from the University of Nottingham. He is a former member of Network of Excellence for Functional Biomaterials, Galway, Ireland. He was also a member of the EPSRC Centre for Innovative Manufacturing in Regenerative Medicine, Nottingham, UK. He is currently a member of the Recent Appointees in Polymer Science (RAPS) committee, part of the Macro Group UK. He is also a member of The East Anglian Musculoskeletal Research Alliance, and UEA musculoskeletal Research Group. He is an inventor of an awarded patent “Responsive Magnetic Particulate Dispersion for Ex-vivo Cellular Expansion on 2D and 3D Cell Culture and Cell Recovery via Magnetic Separation”. His current research group is focused on the development of microcarriers and their application in drug delivery, tissue engineering and regenerative medicine.
Athina Bakopoulou is an Assistant Professor at the Department of Prosthodontics of the School of Dentistry, Faculty of Health Sciences of the Aristotle University of Thessaloniki, (A.U.Th) in Greece. Since 2009 she is a Visiting Research Fellow at the Department of Conservative Dentistry, Periodontology and Preventive Dentistry of the Medical University of Hannover (MHH) in Germany. Her published work includes more than 30 original research papers in international peer-review journals focusing in the fields of dental tissue engineering and biocompatibility of dental materials, as well as several book chapters on Prosthodontics and Regenerative Dentistry. She has been serving as regular Reviewer for several distinguished international scientific journals, including Journal of Dental Research, Dental Materials, Clinical Oral Investigations, Archives of Oral Biology, Stem Cells International, Stem Cells and Development, PLoS One etc. She has presented her research and clinical work in more than 120 international and national meetings and conferences and has been the recipient of significant awards, including the first award at the 11th (Crete, Greece, 2005) and 12th (Fukuoka, Japan, 2007) Meeting of the International College of Prosthodontists (ICP), as well as the Senior Robert Frank Award at the 44th IADR-CED Meeting (Munich, Germany, 2009), as well as the 96th IADR-General Session Meeting (London, UK, 2018). She is the national representative of the Young Scientists Forum (YSF) of the European Society of Biomaterials (ESB) and member of the organizing committee of the 28th Annual ESB Conference, 4-8 September, Athens, Greece. She is currently principal investigator of several on-going research projects on dental tissue regeneration, oral stem cells and biological responses to biomaterials.
Benjamin Gantenbein is an Associated Professor of the Medical Faculty and Group Head of the Tissue & Organ Mechanobiology (TOM group) at the Institute of Surgical Technology & Biomechanics Department in the Medical Faculty at the University of Bern. His research focuses on intervertebral disc repair using biomaterials and scaffolds, mesenchymal stem cells or a combination thereof. He started his career at the University of Bern in the field of evolutionary biology / phylogenetics where he completed his Master of Science degree and also his PhD at the Computational and Molecular Population Genetics (CMPG) laboratory at UBERN. He then received two fellowships (SNF young scientists and a Marie Curie IHP substitute) to focus on animal molecular evolutionary rates at the Institute of Evolutionary Biology, University of Edinburgh. From there he moved to the Genetics and Molecular Ecology Laboratory at Cambridge University, where he focused on recombination in animal mitochondria. Before the current assignment, Prof. Gantenbein entered into the field of intervertebral disc research at the AO Research Institute in Davos, where he acquired experience in modern concepts of tissue engineering and regenerative medicine. He is active in the field of tissue engineering and stem cell research (www.stemcellsbern.ch). He is active in the field of bioreactor design and research using a wider range of bone & joint tissues. He teaches lectures on Principles of Human Medicine and Tissue Engineering in the Biomedical Masters course. He also teaches regenerative medicine at the University of Fribourg.
Benjamin Missbach is Project Manager at the Ludwig Boltzmann Gesellschaft (LBG) — Open Innovation in Science Center. He holds a PhD in Nutritional Science with a focus on cognitive-behavioral aspects of food intake and has a Master’s degree in Public Health Nutrition. He authored several peer-reviewed publications in the field ranging from public health to eating behavior research. Since early 2017 he is a part of the Ludwig Boltzmann Gesellschaft developing methods of Open Innovation in Science. He is specialized in crowd-based processes (Crowdsourcing, Crowdfunding), Public Engagement in Research and Open Science. He is passionate to innovative within the research system by making science more permeable across several steps of the research process.
Bernd Rolauffs, M.D., is a German scientist, board-certified orthopaedic trauma surgeon, Professor of Tissue Replacement, and Chair of the multi-disciplinary “Tissue Replacement, Regeneration & Neogenesis” research center that has been founded in 2016 at the Freiburg University Medical Center, Germany. During his early stage of residency, he completed a two-year post-doctoral research fellowship in Prof. Klaus Kuettner’s laboratory in the Dept. of Biochemistry, Rush University, Chicago, followed by a second, three-year post-doctoral fellowship in Prof. Alan Grodzinsky’s Center for Biomedical Engineering at the Massachusetts Institute of Technology (MIT) in Boston. He additionally received a six-month clinical scholarship in the Department of Orthopedic Surgery, Brigham and Women's Hospital, at Harvard Medical School. After completing his residency in Orthopedics and Trauma Surgery at the BG Trauma CenterTuebingen in Germany, he established and then headed the Laboratory for Molecular Biomechanics in Tuebingen from 2009 – 2016. He was appointed deputy director of the Siegfried Weller Institute for Trauma Research in 2012, Visiting Professor in the Dept. of Biochemistry at Rush University, and Visiting Scientist in the Center for Biomedical Engineering at the Massachusetts Institute of Technology (MIT). Prof. Rolauffs is interested in the mechano-biology of cells, tissues, and bio-artificial surrogate tissues, and his expertise is focused on early degenerative changes of musculoskeletal tissues, in particular articular cartilage. It also includes broader research topics such as chondrocyte and stem cell biology, biomaterials, and, as a unique contribution to the field, the spatial organization of cells and the cellular geometry within native tissues, to better understand and diagnose healthy versus diseased tissue states. For a better overview please see the lab’s web site: www.gerninfreiburg.de.
Bert Müller received a diploma in mechanical engineering, Berlin 1982, followed by M.Sc. degrees in Physics and English both from the Dresden University of Technology in 1989. In 1994, he obtained a Ph.D. in experimental physics from the University of Hannover, Germany. For his achievements, he was granted with the Morton M. Traum Award of the American Vacuum Society in 1994. From 1994 to 2001, he worked as a researcher at the Paderborn University, Germany, as Feodor Lynen Fellow and research associate at the EPF Lausanne, Switzerland and as team leader at the Physics Department, Materials Department and Department of Information Technology and Electrical Engineering at ETH Zurich, Switzerland. He became a faculty member of the Physics Department at ETH Zurich in April 2001. After his election as Thomas Straumann-Chair for Materials Science in Medicine at the University of Basel, Switzerland and his appointment at the Surgery Department of the University Hospital Basel in September 2006, he founded the Biomaterials Science Center in March 2007. Currently, this center hosts researchers from many fields dealing with nanotechnology-based artificial muscles for incontinence treatment, compliant electrodes for brain stimulation, mechano-responsive nano-containers for targeted drug delivery for the treatment of cardiovascular diseases, high-resolution X-ray imaging to visualize the human body down to the molecular level in health and disease, and further applications of nanosciences in medicine and dentistry. The mission of the research team can be summarized by employing physical principles for human health. Professor Müller is author of more than 300 publications in a wide variety of journals and teaches at the Physics Department of ETH Zurich and the University of Basel as well as supervises doctoral students from medicine, dentistry, physics, nanosciences, and biomedical engineering. In 2014, he was elected as Fellow of SPIE and in 2015 as an active member of the European Academy of Sciences and Arts.
Britt Wildemann is head of the Experimental Trauma Surgery at the University Hospital Jena, Germany, since June 2018, and also leads the group "Biological Basis of Musculoskeletal Regeneration" at the Berlin-Brandenburg Center for Regenerative Therapies, Charité-Universitätsmedizin Berlin, Germany, since October 2009. She is a biologist and received her PhD in neurobiology at the Freie Universität Berlin and started working in the field of musculoskeletal research in the year 1999. Her research groups investigate the regeneration of the musculoskeletal system with the main focus on tendon pathologies, osseous regeneration and infection prophylaxis and treatment. Using in vitro studies of different cell types and different animal models, they continue to explore various approaches to influence tendon and osseous healing and to treat infections.
J Carlos Rodríguez-Cabello, PhD, holds a degree in Chemistry and a degree in Physics. He got his PhD in physics (1994) studying the rheological properties and real-time relationship between macroscopic and molecular events of deforming polymers under the supervision of Prof. JC Merino at the University of Valladolid. After taking different positions, he is full Professor (2012) at the department of Condensed Matter Physics in the University of Valladolid (Valladolid, Spain). He is the director of the BIOFORGE laboratory, a multidisciplinary research group founded by him 25 years ago. This lab is specialized in the design and synthesis of recombinant protein polymers (recombinamers), which constitute a continued pioneer effort of his group in the development of advanced biomaterials and their related systems for uses in biomedical areas such as nanomedicine and regenerative medicine. In addition to that, his group is also involved in more fundamental research directed to the understanding the relationship between protein sequence and function, especially in those aspect related to dynamic properties of proteins and their self-organization capabilities. He has been the PI and/or coordinator of more than 50 funded research projects at national and European levels. During this time, he has published over 150 papers and book chapters in international journals of high IF. He also is the inventor of 17 patents, 6 of them transferred to the industry. He has also founder of two technology-based companies, being the current CEO of one of them, TPNBT S.L. He is also the holder of a number of awards in recognition to the achievements of his career.
Caroline Curtin obtained her BSc in Biomedical Science from the National University of Ireland, Galway (NUIG) in 2004 followed by her PhD in 2010 from the Regenerative Medicine Institute at NUIG. During this time, she also worked as a Research Assistant for Cellular Arthroplasty for Regeneration in Arthritis (CARA), NUIG in collaboration with an industrial partner, Smith & Nephew, a global leader in medical technology, and the Irish Industrial Development Authority, assessing the potential of adult stem cells as a treatment for arthritis with a strong translational, commercialisation and fast-track product development focus. She was recruited as a post-doctoral researcher to the Tissue Engineering Research Group (TERG) in the Royal College of Surgeons in Ireland (RCSI) in 2010 assessing smart scaffolds for bone tissue regeneration under the supervision of Professor Fergal O’Brien. Dr. Curtin is currently employed as a Lecturer in Anatomy and Principal Investigator in the TERG. She is co-supervisor of 3 PhD students, with 1 PhD graduated, has supervised numerous MSc and undergraduate students and has authored > 17 research articles in leading international journals. She is an ad-hoc reviewer for >15 international journals, has presented at > 40 international conferences, and been an invited speaker and chair at a number of conferences. Her research focuses on development of gene-activated scaffold systems for tissue engineering with a particular focus on bone and cartilage, and utilising scaffolds as 3D tumour models for development of novel cancer treatments.
Carsten Werner is professor of biofunctional polymer materials at the TU Dresden Center for Regenerative Therapies, directs the biomaterials program at the Leibniz Institute of Polymer Research Dresden (within the Max Bergmann Center of Biomaterials), Germany, and holds an adjunct faculty position at the Institute of Biomaterials and Biomedical Engineering, University of Toronto, Canada. His research aims at recapitulating functionalities of living matter in engineered polymer materials and includes studies on electrosurface phenomena, hemocompatible interfaces, cell-instructive materials platforms for regenerative therapies and tissue models, and biomimicry approaches to surface engineering. Carsten Werner has published more than 350 peer reviewed research articles, organized several scientific conferences and is co-founder of a successful spin off enterprise.
Caterina Da Re joined Frontiers in 2017 after completing her PhD in Genetic and Molecular Biology of Development. She has worked first as a Specialist in Frontiers in Physiology and she is now Journal Development Manager of Frontiers in Bioengineering and Biotechnology. Prior to this, Caterina was a geneticist primarily interested in mitochondrial disorders.
Catherine Le Visage, PharmD, PhD, is a Research Director and the Deputy Director of the Regenerative Medicine and Skeleton (RMeS) laboratory at the University of Nantes, France (www.rmes.univ-nantes.fr). She was trained as a Pharmacist, she received her PhD in Pharmaceutical Technologies and then performed a post-doctoral training at the Johns Hopkins School of Medicine, Biomedical Engineering Department (Baltimore, USA) in Prof Kam Leong’s laboratory with a focus on soft tissue engineering projects. In 2007, she joined the French National Institute of Health and Medical Research (INSERM) as a tenured Senior Research Scientist to investigate chemically cross-linked polysaccharides hydrogels as cardiac cell delivery systems and vascular replacement scaffolds. In 2013, she was appointed as a Research Director and joined the Regenerative Medicine and Skeleton laboratory in Nantes. In the "Skeletal Physiopathology and Joint Regenerative Medicine" team headed by Prof J. Guicheux, she investigates hydrogels as i) tools for stem cell-based organogenesis and ii) carriers of cells or bioactive molecules in the context of intervertebral disc disease and osteoarthritis. Her current research interest lies in bioengineering approaches to orchestrate molecular and physical signals that regulate stem cell fate. Her most recent works have focused on the development of self-setting hydrogels for long-term delivery of biochemical cues such as growth factors and chemokines to address intervertebral disc disease and osteoarthritis. She co-authored 58 publications in ISI-indexed journals (h-index 23), 11 patents and gave 40 invited lectures.
Catherine Van Der Straeten, MD, PhD, FIOR is head of the Health Innovation and Research Institute of Ghent University Hospital and Clinical professor at Ghent University. She is a rheumatologist and has coordinated and conducted orthopaedic surgery research for 30 years focussing on R&D of implants, and on bone and tissue regeneration and the clinical results of these interventions. In this regard she has conducted several clinical trials on meniscus allograft transplantation, meniscus regeneration and artificial replacement. She is Medical Director of the Ghent University hospital Biobank, Chair of the ScienSano (Belgian Federal Knowledge Centre for Health) General Board and Board of Directors and honorary senior clinical lecturer at Imperial College London. She was the 2018 President of the International Society of Technology in Arthroplasty. She was member of the Working Group on safety of metal implants at the SCENIHR of the European Commission and member of the External Expert Advisory Board (EEAB) of EU Life Long Joints Project.
Chaozong Liu is Professor of Orthopaedic Bioengineering at UCL Institute of Orthopaedics & Musculoskeletal Science in associate with the Royal National Orthopaedic Hospital Stanmore. He is the MSc in Musculoskeletal Science Course Tutor within UCL Division of Surgery and Interventional Science. He leads UCL Orthopaedic Bioengineering Research Group, and his current research is directed toward biomedical devices processing for enhancing the treatment of musculoskeletal disorders. Specifically, his research interest includes (1) design and development of scaffolds for musculoskeletal tissue engineering and regenerative medicine. (2) Customized medical devices for intervention of musculoskeletal disorders. (3) biomedical device surface processing for regulate protein adsorption and cells attachment. This is a growing area of interest at UCL Surgical & Interventional Science. My research in this area is supported by ARUK, EPSRC, Innovate UK and European Unit H2020 Programme.
Chiara Vitale-Brovarone is Full Professor in Materials Science and Technology at the Department of Applied Science and Technology, Politecnico di Torino where she leads the IRIS group (Improving Regeneration by Intelligent Scaffolds). She chairs the following courses: Materials Engineering (Master Science Degree in Materials Engineering) and Materials and engineered surfaces for application in medicine (Master Science Degree in Biomedical Engineering). Her research interests are mainly related to the development of innovative biomaterials ranging from the macro to the nanoscale (3D-scaffolds, micro and nanoparticles, resorbable fibers, injectable cements…) and to 3D scaffold biofabrication. Master Degree in Materials Engineering in 1997, Ph.D in Materials Engineering at Politecnico di Torino in 2001, she has won fellowships for research stays at the Ecole de Chimie de Montpellier in France and at the Lawrence Berkeley National Laboratory, California, USA. She has authored 140 papers on international journals, h-index 33 receiving about 3000 citations. She has coordinated the EU-funded projects (MATCH, BIORESS) and she has been Team leader for the EU project RESTORATION. At present, she is coordinating the H2020 project MOZART, funded in the NMP-6-2015 call which involves 11 partners (5 SMEs). She is the Principal Investigator of the ERC-CoG-2015 grant BOOST and of the GRACE project funded by the Italian Minister for Research (FARE Ricerca in Italia).
Chris Sammon, PhD, is Professor of Polymer Science and Head of the Polymers, Composites and Modeling Research Centre, within the Materials and Engineering Research Institute at Sheffield Hallam University, UK. He is a Fellow of the Royal Society of Chemistry and is named inventor on three granted patents in the area of injectable hydrogels for applications in regenerative medicine. His current research interests include the design, characterisation and synthesis of polymer systems for regenerative medical and drug delivery applications. He is a world leader in the application of vibrational spectroscopy to investigate the distribution and mobility of water in polymeric systems; including synthetic and natural biopolymers, hydrogels, pharmaceutical systems, cellular materials, saline separation systems, plastiols and cellulose ethers. He is passionate about outreach activities and regularly takes science into local schools and local bars to engage and inspire the young, the old and the inebriated!
Christine Le Maitre is Professor of Cell Biology and Tissue Regeneration at Sheffield Hallam University where she heads the Cell Biology and Tissue Regeneration Research Group. Christine gained her PhD from Manchester University, and following 5 years of postdoctoral research, moved to Sheffield Hallam University in 2008 and established her own research group. Her research group is an interdisciplinary research group with strong collaborations with the Materials and Engineering Research Institute together with the Biomolecular Sciences Research Centre. She was promoted to reader in 2014 and Professor in 2017. Her research to date has led to 2 patents, over 65 publications with ~4750 citations a current H index of 31 and ~18 million in research grant income to date. Christine is passionate about public engagement and has headed up a successful Welcome trust funded public engagement project which involved interactive exhibitions visited by ~20,000 individuals. She has been invited to present her research at national and international meetings and is an elected committee member of various societies and chairperson for DISCs. She has supervised 9 PhD students to completion and currently supervises 7 further students and is currently Head of Research Degrees for the Faculty of Health and Wellbeing at Sheffield Hallam University.
Christophe Hélary, PhD, got his Ph.D degree in Tissue Engineering and Biomaterials from Sorbonne University, Paris, France in 2010. In 2012, he became a research engineer at Laboratory of Condensed Matter Chemistry of Paris (LCMCP). The Christophe’s research activities in the past 10 years have been focused on the development of dense collagen hydrogels for biomedical applications (severe burns, chronic wounds, intervertebral disc degeneration and bone defects). He uses collagen in dense phase to improve stability, physical and mechanical properties of hydrogels. Since 2013, his research orientation is towards the development of composite hydrogels to improve physical and biological properties of biomaterials or to deliver biomolecules (drugs, therapeutic genes) in a sustained and controlled manner. He associates dense collagen with synthetic polymers (PLGA, PCL, PLA), natural polymers (alginate, hyaluronic acid), silica nanoparticles or hydroxyapatite. Dr Hélary has published 43 articles and is an inventor on 2 patents. He is a member of the Biohydrogel Society and BIOMAT, the french society for biomaterials. He is Associate Editor of Scientific Reports.
Christopher Mann completed his PhD at the University of Western Australia (UWA) in the field gene therapy for Duchenne muscular dystrophy in 2003 and subsequently went on to work as a post-doctoral researcher for 10 years at Kings College London (KCL) in the UK and Universitat Autonoma de Barcelona (UAB) and Universitat Pompeu Fabra (UPF) in Spain in the fields of gene therapy, muscle disease and development, and immunology. Since January 2013 he has been working in regulatory affairs and project management with a focus on biotechnological projects and advanced therapies including working closely with many companies and research groups in establishing translational pathways for early and late stage medicinal product development.
Chunming Wang (CM) is an Associate Professor at the University of Macau, Macau SAR. He received his Bachelor and Master’s degrees in Biochemistry from Nanjing University (China) and obtained his PhD in Biomedical Engineering from Nanyang Technological University (Singapore). He undertook his postdoctoral training at the University of Cambridge (UK), working in Wilhelm Huck’s group at Department of Chemistry, in collaboration with Fiona Watt’s laboratory at the Wellcome Trust Cambridge Stem Cell Research Centre. In October 2012, CM took the Assistant Professorship at the University of Macau and won promotion to Associate Professor in 2018. As Principal Investigator, CM has secured 11 research grants from agencies in Macau and on mainland China. He has published articles as (co-)first/corresponding author in Advanced Drug Delivery Reviews, Advanced Functional Materials, Advanced Science, Biomaterials, Chemical Communications, Trends in Biotechnology and ACS Nano, among other recognised journals. His current research focuses on devising biomaterials to modulate macrophage behaviour for enhanced tissue regeneration. Because Macau has joined the EU Horizon project under a special partnership scheme, CM invites collaborations with researchers from across Europe.
Cian O’Leary is a graduate of Pharmacy from University College Cork and subsequently went on to receive a Master in Pharmacy from the Royal College of Surgeons in Ireland. Thereafter, he was awarded a PhD postgraduate scholarship under the BioAnalysis and Therapeutics (BioAT) programme, with a PhD in tissue engineering and regenerative medicine. He has been recognised for distinction in academia with numerous conference awards and several fellowships, including a European Molecular Biology Organisation (EMBO) fellowship to Mainz, Germany, and a Fulbright scholarship to UC San Diego. Now, as principal investigator and assistant professor in RCSI, his current research activities include respiratory tissue engineering, pulmonary fibrosis, and epithelial cancers.
Ciara Murphy received her PhD in Biomedical Engineering from the Royal College of Surgeons in Ireland (RCSI) in 2010. In 2011, she began a post-doctoral fellowship in Prof David Little's orthopaedic research group in University of Sydney, Australia whereby she applied her experience in tissue engineering to develop novel therapeutic approaches to augment bone healing in challenging orthopaedic defects. In 2015, Ciara returned to Ireland as Assistant Professor in the School of Medicine, University College Dublin (UCD), Ireland, before returning to the Tissue Engineering Research Group (TERG) and RCSI in 2017. Ciara is the recipient of the prestigious New Investigator Recognition Award (NIRA) from the Orthopaedic Research Society (ORS) (2014) and Marie Skłodowska-Curie Fellowship (2016). She is also a PI in Science Foundation Ireland funded Advanced Materials and BioEngineering Research (AMBER) centre. Her research interest is developing advanced biomaterials as innovative platforms for disease model systems and targeted therapeutic delivery platforms for tissue repair, and has produced 19 publications in top tier journals that have achieved over 2100 citations. Her research focus is on the study of cell-matrix interactions in metabolic bone disease, such as osteoporosis, to design bone metabolism targeted therapies and technologies to treat metabolically impaired bone defects.
Claudia Di Bella is an academic orthopaedic surgeon highly specialised in musculoskeletal oncology, advanced robotic assisted surgery and 3D printing. Dr Di Bella is the leader of the Cartilage Regeneration Program of Research at the University of Melbourne (Australia), centred over the use of advanced 3D printing technologies, including surgical 3D bioprinting, robotics and stem cells for the regeneration of the musculoskeletal system. Dr Di Bella has recently received the prestigious Royal Australasian College of Surgeons Senior Lecturer Fellowship and won the Australian and New Zealand Orthopaedic Research Society (ANZORS) Early Career Award. Dr Di Bella has led her team to successfully secure more than 15 national peer reviewed grants, reinforced and strengthened national and international collaboration with key players in the field, and strongly contributed to the advances of the Biofab3D, the first Australian biofabrication hub embedded in the hospital setting. The successes of Dr Di Bella’s team have been recently recognised internationally (winner of the Orthoregeneration Award for the most innovative work in orthoregeneration) and nationally (Finalist at the prestigious NSW Eureka prize for Excellence in Interdisciplinary Scientific Research), and showcased by national media such as ABC news and National Geographic. Dr Di Bella is very passionate about gender equality in STEM-M, and for this reason she is a mentor in the academic surgery program of the University of Melbourne as well as a mentor for women in medicine at St Vincent’s Hospital.
Cristina Esteves, PhD, is a Research Fellow at the Roslin Institute in Edinburgh. Before moving to UK, she worked at the University of Wisconsin-Madison and then at the University of Iowa. Her research focus in Mesenchymal Stem/Stromal Cell (MSC) biology and potential for tissue regeneration in domestic species, particularly in relation to antimicrobial therapy. Dr. Cristina Esteves' studies resulted in the isolation and characterisation for the first time of equine MSC sub-populations (pericytes and adventitial cells), which due to increased purity, provide a relevant alternative to traditional MSC populations for clinical applications not only in veterinary species but also in humans. Her recent studies also showed that MSCs possess antibacterial properties and could potentially be used against infection. As antibiotic resistance constitutes a major health challenge not only in humans but also in animals, MSCs are emerging as a relevant alternative therapy in the combat of infection. Her research is funded by the Biotechnology and Biological Sciences Research Council, Horse Betting Levy Board and PetPlan Charitable Trust. Dr. Cristina Esteves is also actively involved in Public Engagement.
Daniel Eberli, MD, PhD, is Senior Attending Physician at the Department of Urology (University Hospital Zurich) since 2011. Due to his continued research in the field of Regenerative Medicine for over 14 years, he received his “professor ad personam” in 2017 and holds the chair for “Regenerative Urology”. Daniel Eberli graduated medical school at the University of Zurich (1997) and continued his education with a molecular medicine PhD program at Wake Forest University (2007), where he worked on techniques to bioengineer a functional sphincter muscle. Back in Switzerland, he built a Laboratory for Stem Cell Therapy and Tissue Engineering (2008) and continued the research by expanding the application fields. Daniel Eberli habilitated at the department of Urology (USZ), doing research on “Adult stem cells of Tissue Engineering of urinary Sphincter and Bladder” (2011). Throughout his career he obtained a number of competitive grants supporting his novel research. Evaluated on the basis of the criteria “excellence, impact and quality and efficiency of implementation”, his research efforts were funded by the prestigious EU H2020 program for translating the know-how from bench to bedside. Having the experience in the field of Regenerative Medicine and Tissue Engineering, Daniel Eberli is now expanding his career achievements by being the Principal Investigator (PI) and Mentor of the Associate project MUS.I.C. As a Sponsor-Investigator of the clinical trial, he is directly responsible for the GCP-compliant implementation of the first-in-man ATMP study for applying the muscle precursor cells into patients.
Daniel Kelly received his BA, BAI and PhD from Trinity College Dublin. After working in the medical device industry, he joined the School of Engineering in Trinity College Dublin as a lecturer in 2005. He is now Professor of Tissue Engineering and Director of the Trinity Centre for Bioengineering. In 2008 he was the recipient of a Science Foundation Ireland President of Ireland Young Researcher Award. In 2009 he received a Fulbright Award to take a position as a Visiting Research Scholar at the Department of Biomedical Engineering in Columbia University, New York. He is the recipient of three European Research Council awards (Starter grant 2010; Consolidator grant 2015; Proof of Concept grant 2017). Prof Kelly leads a large multidisciplinary musculoskeletal tissue engineering group based in the Trinity Centre for Bioengineering. The goal of his lab is to understand how environmental factors regulate the fate of adult stem cells. This research underpins a more translational programme aimed at developing novel tissue engineering and 3D bioprinting strategies to regenerate damaged and diseased musculoskeletal tissues. To date he has published over 140 articles in peer-reviewed journals.
Daniel Ruiz-Molina earned his PhD in polyradical dendrimers at the Institut de Ciència de Materials de Barcelona (ICMAB-CSIC). He then took a postdoctoral position at the University of California San Diego (USA) for three years working on functional molecular materials. Since 2001 he has held a permanent position as a Spanish National Research Council (CSIC) researcher and most recently at the ICN2, where he is the leader of the ICN2 Nanostructured Functional Materials Group also known as NanosFun. His main research areas include the fabrication of biomimetic functional adhesives, colloids and thin-films for smart bio-applications including encapsulation and drug delivery, imaging, biofunctional coatings and more recently tissue engineering.
Daniel Stuckey is a British Heart Foundation Intermediate Basic Science Research Fellow and leads pre-clinical cardiovascular imaging at UCL’s Centre for Advanced Biomedical Imaging. His research focuses on developing and applying novel multi-modality imaging approaches, including cardiac MRI, ultrasound and PET/SPECT/CT, for the investigation of cardiomyopathy and validation of new therapies. Daniel has published over 50 papers in leading journals including Cell Stem Cell, Science Translational Medicine and Nature Communications; holds grants from the BHF, MRC and Wellcome Trust; and is a PI on the BHF’s Cardiovascular Regeneration Centre. Before becoming a group leader at UCL in 2013, Daniel undertook his DPhil at The University of Oxford with Kieran Clarke and Carolyn Carr, then moved to Imperial College London to train with Michael Schneider and Sian Harding.
Darja Marolt is the bone research area manager at the Ludwig Boltzmann Institute for Experimental and Clinical Traumatology in Vienna, Austria. She conducted her doctoral studies of adult stem cells for bone tissue engineering at the University of Ljubljana, Slovenia and as a visiting PhD student to the Harvard - Massachusetts Institute of Technology Health Sciences and Technology Program in Boston, USA. She afterward joined the Department of Biomedical Engineering, Columbia University in New York, USA for her postdoctoral studies with human pluripotent stem cells. Her research was supported by the Young Researcher Award, Republic of Slovenia and by the New York Stem Cell Foundation - Stanley and Fiona Druckenmiller Postdoctoral Fellowship. In 2010, Dr. Marolt was an inaugural recipient of the New York Stem Cell Foundation - Helmsley Investigator Award and founded the bone regeneration laboratory at the New York Stem Cell Foundation Research Institute in New York, USA, which first reported engineered bone tissue substitutes from human induced pluripotent stem cells. Upon her return to Europe, she was awarded the Marie Skłodowska-Curie International Fellowship to join the Ludwig Boltzmann Institute and the Austrian Cluster for Tissue Regeneration, where she is currently investigating new approaches to improve bone regeneration in elderly patients.
**David Hoey** is an Associate Professor in Biomedical Engineering within the Department of Mechanical and Manufacturing Engineering and PI within the Trinity Centre for Bioengineering in Trinity College Dublin (TCD). Dr. Hoey leads a multidisciplinary experimental mechanobiology and biomaterials research group where his goal is to integrate mechanics into the understanding of the molecular basis of skeletal physiology and disease. Dr. Hoey's research has discovered novel mechanisms by which bone can sense and respond to a biophysical stimulus. In particular, he is focused on determining indirect and direct biophysical regulation of skeletal stem cell contributions to bone formation and repair and how this is altered in disease. These platforms have potential to result in new therapeutics and biomaterials that mimic the beneficial effect of biophysical stimuli and treat orthopaedic diseases such as osteoporosis. He was awarded the European Research Council Starting Grant in 2013 and Proof of Concept in 2018 and his group is currently funded by the ERC, IRC, MSCA and the SFI centres ‘AMBER’ and ‘CURAM’.
David Eglin is Principal Investigator and leader of the Polymers team at the AO Research Institute Davos in Switzerland. He has extensive expertise in the synthesis and the processing of responsive materials based on biopolymers such as hyaluronic acid and collagen. His group is notably using additive manufacturing technologies for both basic understanding of biomaterials and cells interaction, and for translational research in the orthopaedic field. In 2011, David Eglin was given the Jean Leray award by the European Society for Biomaterials for outstanding research contributions to the field of biomaterials. He has published over 100 peer-reviewed articles and book chapters, as well as 8 patents. He is president of the Swiss Society for Biomaterials and Regenerative Medicine and council member of the European chapter of the TERMIS Society.
David Musson, PhD, is an Auckland Medical Research Foundation Senior Research Fellow who leads the tendon and orthopaedic research as part of the Bone and Joint Research Group, University of Auckland. He serves on numerous local committees, and is on the committee for the Australia and New Zealand Orthopaedic Research Society, and he was the main organiser and host of their annual scientific meeting in Auckland, 2015. He also has active involvements with the Matrix Biology Society of Australia and New Zealand and was co-chair of their 2018 scientific meeting. His research is predominantly basic science driven by clinical questions, incorporating in vitro and pre-clinical in vivo studies. As such he supervises a mix of postgraduate students with scientific and engineering backgrounds, and medically-trained orthopaedic trainees. Particular interests have been in understanding musculoskeletal disease progression through cell and molecular biology approaches, better understanding cell-material interactions, and assessing potential adjuncts for improving tendon and bone healing.
Debby Gawlitta, PhD, is a biomedical engineer who received her degrees from the Eindhoven University of Technology. In 2007, she started to work on bone and cartilage tissue regeneration at the department of Orthopaedics, University Medical Center in Utrecht, the Netherlands. There, she received a prestigious Dutch innovation grant to pursue endochondral bone regeneration from a cartilage template with bone marrow-derived stem cells. Her second research line is directed at coculturing of different stem/progenitor cells for vascularization of engineered bone tissue. In 2014, she established her own group at the department of 'Oral and Maxillofacial Surgery' of the UMC Utrecht where she continued the two research lines, with a focus on translation for maxillofacial applications. In recent years, her lab has developed novel gelatin-based hydrogel formulations for vascularized bone regeneration. In parallel, efforts were directed at investigating immunological aspects of endochondral bone regeneration. Dr. Gawlitta was a member of the local organizing committee of the European Society for Biomaterials (ESB) 2018 meeting. She currently holds a position as Associate Professor and is heading her lab in the Regenerative Medicine Center Utrecht.
Denitsa Docheva graduated with two master degrees, one in biology and one in chemistry from the Faculty of Natural Sciences in Plovdiv, Bulgaria (1999) and holds PhD in Molecular Biology for her studies at the Max-Planck-Institute for Biochemistry, Martinsried, Germany (2002-2004). Since 2005, she has worked at the Ludwig-Maximilians-University (LMU) in Munich and in 2006, she established the Tendon Research Group in the Experimed Laboratory, Department of Surgery, LMU. She also holds second doctoral degree Dr. habil. med. in Experimental Surgery from the LMU (2012). In September 2016, she was appointed full Professor for Experimental Trauma Surgery at the Department of Trauma Surgery of the University Regensburg Medical Centre. In the last 15 years, she has published more than 60 articles and according to ISI Web of Science she has citation sum of 1700 and h-index of 21. Her laboratory investigates the basics and coherence of joint diseases and connective tissues with special focus on tendons and ligaments. The quest for explanations and solutions for clinical problems is carried out using different experimental approaches and in a multidisciplinary team. The research spans from 2D and 3D in vitro models to various in vivo models (transgenic, disease, injury and cell-based therapy models). Stem/progenitor cells from different species are being investigated in great detail with the aim to decipher age and degeneration-related molecular and cellular changes and consecutively to design innovative and tissue-specific counter therapeutic strategies.
Dennis Link, PhD, received his PhD at the Department of Periodontology and Biomaterials of the Radboud University Nijmegen Medical Center, Nijmegen, the Netherlands in collaboration with the Department of Bioengineering of the Rice University, Houston, TX, USA in 2008. He continued his research in bone tissue engineering as a post-doc at the 3B’s Research Group, Headquarters of the European Institute of Excellence on Tissue Engineering and Regenerative Medicine, University of Minho, Braga, Portugal, where he was also part of the TERMIS-SYIS EU Board in organizing symposia and activities related to young investigators and students, during TERMIS conferences and beyond. After his post-doc he switched in 2011 to industry as a product developer at European Medical Contract Manufacturing (EMCM) B.V. in Nijmegen, the Netherlands where he developed products like allograft bone products, collagen-based tissue engineered products, xenografts for dental applications and anti-adhesive gels. Next, he became a Senior Scientist as Osteo-Pharma B.V. in Oss, the Netherlands, developing products for orthopedic and dental applications for the local treatment of bone fractures and bone defects. Currently, he is a Business Development Manager at BioConnection B.V. in Oss, the Netherlands where he connects young and innovative biopharmaceutical companies to state-of-the-art-GMP manufacturing facilities and broad range of support services.
Dimitrios Stamatialis graduated in 1989 from the University of Athens – Greece (Chemistry) and obtained his PhD at NRC “Demokritos” (Athens - Greece) in 1995 in the field of physical chemistry and membranes. He is currently full professor of (bio)artificial organs and coordinator of the research domain of Bioengineering technologies at the TechMed centre of the University of Twente in the Netherlands. Prof. Stamatialis has long experience in the field of biomaterials, biomedical membranes and (bio)artificial organs (currently supervises 5 PhD-students and 4 postdocs) and he has been involved in numerous projects leading to products and applications, some licensed to companies. He is author of more than 140 scientific papers and inventor of 8 patents. He has various international activities, including: Coordinator of the EU Marie Curie ITN project “BIOART” which aims to develop prototype devices for the treatment of kidney and liver disease; Member of the EUTox group, a working group dealing with coordination of European research on uremic toxins; Editor of the “international journal of artificial organs” - the official journal of the European Society of artificial organs; Member of various scientific organizing and scientific committees of several international conferences and many others. **Dror Seliktar** is an associate professor on the Technion’s Faculty of Biomedical Engineering. His primary area of interest is in the field of tissue engineering and regenerative medicine with an emphasis on hydrogel biomaterials and biomechanics. His academic research focuses specifically on novel hydrogel biomaterials for tissue engineering, regulation of morphogenesis via physical properties in 3-D culture, and mechanobiology in tissue engineering. His applied research in tissue regeneration has lead to the discovery of a new biomaterial, Gelrin™, which has been licensed to a company called Regentis Biomaterials Ltd., of which he is a founder. The technology transfer of the patented Gelrin biomaterial technology from the Technion into human clinical trials, which are currently underway in Europe and USA, has been an integral part of his tenure in the department. He has presented his scientific findings at numerous professional meeting and scientific conferences and has authored or co-authored over 120 publications. He has received several awards for his research and teaching accomplishments, including the prestigious Rita Levi-Montalcini Award. He served as the Director of the Norman Seiden International Multidisciplinary Graduate program in Nanoscience & Nanotechnology. In addition, he was awarded a large-scale international cooperation grant from the Singapore government in the area of cardiac restoration therapies; he served as the founding director and lead PI of this multi-national collaborative endeavour.
Eben Alsberg holds the Richard and Loan Hill Professorship in the Department of Bioengineering at the University of Illinois at Chicago, where he serves as Director of the Alsberg Stem Cell and Engineered Novel Therapeutics (ASCENT) Laboratory. He was previously a professor at Case Western Reserve University in the Departments of Biomedical Engineering and Orthopaedic Surgery from 2005-2018. He received his B.S.E. in Mechanical Engineering and Material Science and Biomedical Engineering, cum laude, from Duke University in 1994. He then went to graduate school at the University of Michigan, Ann Arbor, where he received an M.S.E. in Mechanical Engineering (1998), an M.S.E. in Biomedical Engineering (1998), and a Ph.D. in Biomedical Engineering (2002). Following his graduate studies, he was a Postdoctoral Research Fellow in the Vascular Biology Program at Harvard Medical School. His laboratory focuses on engineering functional biologic replacements to repair damaged or diseased tissues in the body. Complex signals implicated in tissue morphogenesis, repair, and homeostasis are used as inspiration for the development of innovative biomaterials for tissue regeneration. Through the precise temporal and spatial presentation of soluble bioactive factors, mechanical forces, and biomaterial physical and biochemical properties, his lab aspires to create microenvironments that regulate cell gene expression and new tissue formation. He’s co-authored over 115 peer reviewed papers and book chapters, and his work has been recognized with the Ellison Medical Foundation New Scholar in Aging Award, the Biovalley Young Investigator Award from the Tissue Engineering Society International, the Crain’s Cleveland Business Forty Under 40 Award, a Visiting Professorship at Kyung Hee University (Korea), a Lady Davis Fellowship at the Technion (Israel), and election to the American Institute for Medical and Biological Engineering (AIMBE) College of Fellows. The NIH, DOD, NSF, the Ellison Medical Foundation, the Coulter Foundation, the Musculoskeletal Transplant Foundation, the State of Ohio and the AO Foundation have funded his lab’s research. He is active in many professional societies, and currently serves on the Americas Council of the Tissue Engineering and Regenerative Medicine International Society (TERMIS).
Eilis Dowd’s research is focused on developing and validating novel pharmacological, cell, gene and biomaterial therapies for Parkinson’s disease. She received her PhD at the University of Edinburgh, UK, after which she completed post-doctoral research at the University of Cambridge, UK, McGill University, Canada and Cardiff University, UK. She then returned to her home country of Ireland in September 2005 to take-up a tenured position as Lecturer in Pharmacology at National University of Ireland, Galway. Dr Dowd is currently President of Neuroscience Ireland, Ireland’s official neuroscience society, and President of the Network for European CNS Transplantation and Restoration (NECTAR), and she sits on the Governing Councils of both the Federation of European Neuroscience Societies (FENS) and the International Brain Research Organisation (IBRO). She is also Associate Editor of Neuronal Signaling, Section Editor of the European Journal of Neuroscience, and Editorial Board member at Scientific Reports. In her presentation, Dr Dowd will share some of her group’s latest work showing that biomaterials, specifically collagen hydrogels, can dramatically improve the outcome of cellular reparative for Parkinson’s disease, research that was picked-up by the BBC Science Focus Magazine as one of “five incredible advances in brain disease treatment”. She will also show excerpts of a short documentary on this work entitled “Feats of Modest Valour” which contextualises her research to the patient experience. Feats of Modest Valour recently won The Scientist Award (awarded by AAAS and Science Magazine) and Runner-Up People’s Choice Award at the Imagine Science film Festival in New York, and also the Professional Documentary Award at the Raw Science Film Festival in California.
**Eirini G Velliou** is Senior Lecturer (Associate Professor) of Bioprocess & Tissue Engineering, Principal Investigator and Founder of the Bioprocess and Biochemical Engineering group (BioProChem) in the Department of Chemical and Process Engineering at the University of Surrey in the United Kingdom. Her research focus falls within the engineering and validation of novel biomaterial based *in vitro* platforms for studying various biological systems and diseases, i.e., cancer, stem cells differentiation, formulation/communication of bacterial communities and bacterial-host interactions. Furthermore, she is particularly interested on the response and adaptation/resistance of biological systems to environmental stress. Eirini joined the University of Surrey in September 2014 after a postdoctoral appointment of 2 years at Imperial College London (Centre for Process Systems Engineering & Biological Systems Engineering laboratory) where she worked on tissue engineering of healthy & diseased (leukaemia) blood. Prior to joining Imperial College Eirini spent 5 years doing research in Belgium. She worked as a postdoctoral researcher at the Bioengineering Group of the Earth and Life Institute (ELI) of the Université Catholique de Louvain (UCL) in Louvain-la-Neuve, Belgium, where she focused on the optimisation of biofuel and carotenoid production from immobilised micro-algae under light stress, mechanical stress and nutrient deprivation. Eirini holds a PhD from KU Leuven, Belgium (Department of Chemical Engineering), where she worked on an integrated *in vitro/in silico* approach for predicting microbial environmental stress adaptation phenomena in liquid state and in viscoelastic biomaterials. Eirini holds a Masters in Chemical Engineering from the National Technical University of Athens (NTUA), Greece. Eirini has supervised 2 postdoctoral researchers, 7 PhD students and 25 master students to date, has published more than 90 papers in scientific journals, books, and conferences and has recently co-edited a book on Biomedical Systems Optimisation, jointly with Prof Pistikopoulos and Dr Nascu.
Elena M. De-Juan-Pardo, Ph.D., is a Senior Research Fellow and Deputy Director of the Centre in Regenerative Medicine at the Institute of Health and Biomedical Innovation (IHBI) of the Queensland University of Technology. From 2008-2012 she established and led the Tissue Engineering and Biomaterials Group at the Centre of Studies and Technical Research of Gipuzkoa (Spain) and served as Director of the Master in Biomedical Engineering at the University of Navarra (Spain). In 2013 she joined the Centre in Regenerative Medicine directed by world leader D/Prof. Dietmar Hutmacher at IHBI to further expand her interdisciplinary research skills in the areas of biomaterials, tissue engineering and biofabrication. Since then she has led the development of melt electrowriting, a pioneering 3D printing technology that enables the production of highly controlled fibrous scaffolds with tailored architectures and mechanical properties for a variety of applications, with a strong focus on soft tissue engineering. She has secured more than AUD 6.5 million as the lead CI or Co-CI of competitive grants and received multiple prestigious awards, including the Spanish National Prize in Materials Engineering and the Otto-Hahn-Medal of the Max-Planck Society.
Elena Zagaynova graduated from the Nizhny Novgorod Medical Academy in 1995. She received her Ph.D. in 2000 and the Dr. Sciences in Medicine in 2007. She is a Director of the Scientific Research Institute of Biomedical Technologies at Privolzhsky Research Medical University. Her scientific interests include optical bioimaging (optical coherence tomography, multiphoton tomography and microscopy, time-resolved fluorescence imaging) and regenerative medicine: bone formation on the scaffolds with the stem cells, tumor-stem cells interactions, tissue engineering, different trajectories of iPS differentiation. Also, she is a professor of Medical Physics department. In this position her activities include reading lectures and preparing specialists in the field of medical diagnostics, regenerative medicine. She has more than 200 scientific revised publications.
Elisabeth Engel got her PhD in 2003 in bone metabolism diseases in medical school. She was awarded with a postdoc fellow from the Ministry of Science at the Technical University of Catalonia in Biomaterials for bone tissue regeneration and since 2010 has been associate professor at this university. She was appointed principal investigator of the group of Biomaterials for Regenerative Therapies at IBEC in September 2012. She also leads a group at the TERCEL (Spanish network of Cell Therapy) and CIBER-BBN (Research center on Bioengineering, Biomaterials and Nanomedicine). Her research interests include the preparation and design of materials and scaffolds for in vitro and in vivo fundamental studies, and a further focus is the provision of useful tools to assess mechanisms that govern cell behavior in regenerative medicine. She has published more than 95 papers in JRC journals and many invited lectures, and received an award for technological research (Barcelona City Award). Her group conducts several transference and translational projects with pharma and biomedical device industry partners, and participates actively in European projects.
Emmanuel Stratakis is a Research Director at the Foundation for Research and Technology—Hellas (FORTH). He received his Ph.D. in Physics from the University of Crete in 2001 and then he joined the University of California Berkeley as a visiting researcher. He is currently leading the Ultrafast Laser Micro- and Nano- Processing group of FORTH (https://www.iesl.forth.gr/ULMNP). He has over 160 SCI publications and more than 5500 citations and he has coordinated many National and EU grants. Since 2015, he is the Director of the European Nanoscience Facility of FORTH, part of the NFFA-Europe EU Infrastructure, where he is a member of the General Assembly. He is a National Representative to the High-Level Group of EU on Nanosciences, Nanotechnology and Advanced Materials and a National Expert in the NMBP Program Committee of the Horizon 2020. He is also a member of the COST Scientific Committee and a member of the Physical Sciences sectoral scientific council of the National Council for Research & Innovation of Greece.
Eoin O’Cearbhaill, a Lecturer in Biomedical Engineering in the School of Mechanical & Materials Engineering, is a Marie Skłodowska-Curie Fellow, a Principal Investigator in the Trinity Centre for Bioengineering and a Funded Investigator in CÚRAM, SFI Centre for Research in Medical Devices, I-FORM, SFI Advanced Manufacturing Research Centre and AMBER, SFI Advanced Materials & Bioengineering Research Centre. Dr. O’Cearbhaill is a biomedical engineer focused on the development of medical devices, with a particular emphasis on platform technologies, offering smart ways of delivering next-generation therapeutics through minimally invasive approaches. Of note, Dr. O’Cearbhaill developed a mechanical clutch needle that is designed to stop automatically when it enters a cavity, which won 1st prize for Best Innovation at The MIT Sloan Bioinnovations Conference, 2012. Dr. O’Cearbhaill and colleagues at Harvard University invented an adhesive microneedle patch that mechanically interlocks with tissue and can be used to anchor skin grafts, for sustained drug delivery or the extraction of interstitial fluid (IChemE’s Innovative Product of the Year Award 2013, published in Nat Comm). In 2018, Dr. O’Cearbhaill co-founded Latch Medical to commercialise microneedle-based catheter stabilisation devices.
Ernst Reichmann was born in 1955 in Germany. He studied Biology at the Universities of Giessen (Germany) and Bern (Switzerland). In 1988 he obtained his PhD in Bern at the Ludwig-Institute for Cancer Research. In 1989 he started a post doc (and then became staff scientist) at the Institute of Molecular Pathology in Vienna, where he specialized in cell and cancer biology. In 1994 he was offered a group leader position at the Swiss Institute for Experimental Cancer Research (ISREC) in Lausanne (Switzerland). In 2001, he became the head of the Tissue Biology Research Unit (TBRU) in Zurich. He obtained his habilitation (receiving the title of a Privatdozent) in 2004 in the field of experimental surgery, developing and applying his expertise in cell and tissue biology. In 2012 he acquired a professorship at the Faculty of Medicine at the University of Zurich (Switzerland). His areas of expertise are cell biology and tissue engineering. The philosophy of the Tissue Biology Research Unit is to undertake basic research to transform its findings into personalized regenerative medicine. The fields of interest of the TBRU are the mechanisms of vascularization, the generation of blood and lymphatic capillary networks and the characterization of the melanocyte compartment in human skin. The TBRU has developed novel dermal and dermo-epidermal skin grafts, which are presently applied in Phase I and II clinical studies.
Fabrisia Ambrosio graduated with a Master of Science in Physiology-Endocrinology from Laval University in Québec City, Québec and a Master of Physical Therapy from Drexel University. In 2005, Dr. Ambrosio graduated with a PhD in Rehabilitation Science & Technology from the University of Pittsburgh. Also in 2005, she accepted a position as a faculty member in the Department of Physical Medicine & Rehabilitation at the University of Pittsburgh. She holds secondary appointments in the Departments of Physical Therapy, Orthopaedic Surgery, Bioengineering, and Microbiology and Molecular Genetics at the University of Pittsburgh, and is a faculty member of the McGowan Institute for Regenerative Medicine. Dr. Ambrosio’s research has the long-term goal of developing Regenerative Rehabilitation approaches to improve the skeletal muscle healing and functional recovery. Her laboratory investigates the underlying mechanisms by which targeted and specific mechanotransductive signals can be used to enhance donor and/or host stem cell functionality in mouse and human models.
Fabrizio Barberis holds a PhD in Materials Science and Engineering from University of Genoa (Unige) in collaboration with the Lawrence Berkeley National Laboratory - LBNL (Ca). He’s Assistant Professor at University of Genoa where teaches Material Science and Composite Materials for Bioapplications at Biomedical Engineering School (former Engineering Faculty) and at the Natural Science School (former Physics Faculty). His activity is dedicated to biomaterials for internal prosthesis, composite materials and device testing with destructive and non-destructive technics as head of Unige – Zwick/Roell material testing shared Lab while in partnership with the Italian Institute of Welding (GeAM) operates on additive manufacturing with the Medical Schools of Unige and other universities. He was affiliated to the Italian National Research Council (CNR-IENI) and was member of YSF of European Society for Biomaterials ESB. He is active into the standardization for nanotechnologies in electronics and graphene issues as member of the International Electrotechnical Commission – IEC (TC 113 and WG8) and president of the Italian branch of TC 113. He is actively engaged in supporting the Technology-Transfer processes as vice-coordinator of Unige Innovation & Technology Transfer Commission, being also panellist for Start Up selection of several public and private bodies. He’s Unige delegate for “dual use” issues with the Italian Ministry of Economic Development and joins the board of several Master and Specialization Schools dedicated to connect technology and business.
Farida Djouad, received her PhD on Biology and Health from Montpellier University, France, in 2005. She completed a post-doctoral fellowship at the National Institutes of Health (NIH/NIAMS), Bethesda, in Dr Tuan’s laboratory in the field of mesenchymal stem cells and cartilage engineering. Since 2013, she is an Inserm senior scientist (Inserm U1183) and the head of the group “Stem cells, blastema and regeneration” at the Institute for Regenerative Medicine and Biotherapy, Montpellier, France. She pioneered research into the immunoregulatory properties of mesenchymal stem cells. This discovery has, currently, a tremendous impact on clinical trials using mesenchymal stem cells and made her an internationally recognized researcher in the field. In 2011, she obtained the funding “Chercheur d’Avenir” from the Languedoc-Roussillon governing body. Since, she has provided a significant contribution to the understanding of the in vitro and in vivo mechanisms involved in mesenchymal stem cell immunosuppressive properties and therapeutic potential in osteoarticular diseases. Currently, her groups aims at deciphering the basis of the pathological and permissive dialogue between stem cells and immune cells in osteoarticular diseases and epimorphic regeneration, respectively.
Fergal O’Brien is Professor of Bioengineering & Regenerative Medicine, Chief of Basic & Applied Research and heads the Tissue Engineering Research Group based in the Royal College of Surgeons in Ireland. He is also a PI and Deputy Director in the SFI-funded Advanced Materials and Bioengineering Research (AMBER) Centre and is a funded investigator in the CÚRAM Centre for Research in Medical Devices. He is currently a member of the World Council of Biomechanics and immediate-past President of the Section of Bioengineering of the Royal Academy of Medicine in Ireland. He is a co-founder and Chairman of the Scientific & Medical Advisory Board of SurgaColl Technologies, a spinout company from his lab, which has translated 2 technologies for bone and cartilage repair from his lab to the clinic. In addition he is an editorial board member of 5 journals and Subject Editor (Tissue Engineering) for the Journal of the Mechanical Behavior of Biomedical Materials and Co-chaired the World Congress of Biomechanics in Ireland in 2018. He has published over 200 articles in peer-reviewed international journals, presented over 100 invited talks, filed 13 patents/disclosures and supervised over 30 doctoral students to completion. He has a current h-index of 61 (April 2018). Accolades including a Fulbright Scholarship (2001), New Investigator Recognition Award by the Orthopaedic Research Society (2002), Science Foundation Ireland, President of Ireland Young Researcher Award (2004), Engineers Ireland Chartered Engineer of the Year (2005), European Research Council (ERC) Starting (2009), Proof of Concept and Advanced Grants (€3m, 2018), Anatomical Society New Fellow of the Year (2014), Fellowship of Engineers Ireland (2013) and the European Alliance for Medical & Biological Engineering Science (2017), Silver Medal from the Section of Bioengineering of the Royal Academy of Medicine in Ireland (2018) and Membership of The Royal Irish Academy (2018).
Florence Gazeau, PhD in Physics 1997, University Paris Diderot, is senior scientist in CNRS. PI of the Biother group (http://biother.net), she is recognized in the domain of nanomagnetism and nanomedicine. Her research interests include imaging and therapeutic applications of activable nanoparticles, nanotoxicity, life-cycle and long term fate of nanoparticles, mechanobiology of cancer, regenerative medicine and extracellular vesicles for regenerative medicine and drug delivery. She is deputy director of the laboratory Matière et Systèmes Complexes (MSC) at USPC (Université Paris Diderot/CNRS) and one of the leaders for the creation of MSC Med laboratory (Université de Paris 2019). She is author of more than 136 publications (h-index of 46, citations >7500), inventor of 6 pending patents and cofounder of EverZom start up for the production of Extracellular Vesicles.
Franz Weber, PhD, graduated from the University Konstanz (Germany) with a PhD in Biology/Muscle Biochemistry. He completed a 3-year postdoctoral training on muscle cell biology at Cornell University Medical College in New York City and served as a lecturer in the Department of Cell Biology and Anatomy. He spent the following two years at Biochemistry of the ETH Zurich (École Polytechnique Fédérale) working on the lipid uptake from the small intestine. In 1995, he joined the Department of Cranio-Maxillofacial and Oral Surgery at the University Hospital Zurich, and the Dental School of the University Zurich. Beside his obligations at the University of Zurich, he became Director of the European Technical Center of Inion Ltd in Cambridge (UK) in 2005 and occupied this position until 2009. His main area of interest is bone regeneration. His research encompasses bone morphogenetic proteins, delivery systems, bone substitute materials, osteoconduction, epigenetics, additive manufacturing and in vitro bone tissue engineering. Franz E. Weber has authored 112 peer-reviewed research articles published in international journals amounting to more than 4755 citations, and an h-index of 33. He is member of TERMIS (Tissue Engineering international & Regenerative Medicine Society), IADR (International Association for Dental Research), DKG German Ceramic Society, and SSB+RM (Swiss Society for Biomaterials and Regenerative Medicine). He is currently appointed as Professor of Craniofacial and Oral Biotechnology at the Center of Dental medicine of the University of Zurich, member of the Medical and the Science Faculty of the University of Zurich, and as visiting Professor in the Dental School at the University of Hong Kong.
Frédéric Bottausci PhD is a Research Engineer at the Commissariat à l’Energie Atomique et aux Energies Alternatives (CEA) in Grenoble (France). He earned his master degree in fluid mechanics and transfers from the University of Orsay (Paris) and his Ph.D. in fluid mechanics from l’Ecole Superieure de Physique et de Chimie Industrielles de Paris. Dr Bottausci did a postdoctoral fellowship at the University of California, Santa Barbara in the Mechanical Engineering department with Pr. I. Mezic and Pr. C. Meinhart where he worked on microfluidics (design and fabrication of devices, micromixing, dielectrophoresis). He cofounded the startup called Integrated fluidics inc. on microfluidics. In 2008 he joined the CEA and worked on ElectroWetting On Dielectric (EWOD), on packaging and on implantable electrodes. His is currently working on cells encapsulations for biomedical applications and tissue engineering. Dr Bottausci has several patents and published on fluids dynamics, micro-fluidic particle manipulation, EWOD and cell encapsulations.
Garry P. Duffy is a Personal Professor of Anatomy and Regenerative Therapies in the School of Medicine at the National University of Ireland Galway (NUIG). He graduated with a PhD in Regenerative Medicine in 2008 from NUIG. He currently leads a multidisciplinary biomaterials, stem cells and drug delivery group with a large focus on chronic diseases and future clinical translation. The long-term goal of his lab is to develop living implant systems that can house cells or responsive drug systems to replace whole or part organ function. As part of this research goal, Duffy currently leads two European projects funded by the European Union under the Horizon 2020 programme in the area of cell therapies for chronic diseases. The first project entitled, ‘Diabetes Reversing Implants with enhanced Viability and long-term Efficacy (DRIVE)’ aims to develop a novel suite of bio-interactive hydrogels and on-demand drug release systems to deliver cells in a protective macrocapsule in a targeted manner for the treatment of insulin dependent diabetes. The second project entitled, ‘Delivery of advanced therapies training network (DELIVER)’, is a PhD training programme aim to equip PhD graduates with the tools required to become creative, entrepreneurial and innovative leaders in the emerging European advanced therapies sector with a particular focus on stem cell based treatments for Type 1 Diabetes. Both of these EU funded project have a large translation focus with the primary aim to have technologies reach clinical trials in the coming years. He has published 55 papers including a recent paper on cell reservoirs in Nature Biomedical Engineering. He currently collaborates with 10 industry partners and through this interaction the lab has submitted 24 invention disclosures with 8 patent application ongoing. Some of these inventions form the basis of two campus companies focussing on therapeutic delivery and real time monitoring.
Georg Feichtinger is an alumnus of the Vienna Biocentre and graduated with a PhD in Molecular Biology from the University of Vienna. During his MSc and PhD studies he worked at the Ludwig Boltzmann Institute (LBI) for Experimental and Clinical Traumatology in Vienna, Austria, specialising in non-viral gene therapy for bone regeneration under the supervision of Prof. Heinz Redl. As a group leader of the Molecular Biology laboratory at LBI from 2008-2013, he was actively involved in numerous multi-disciplinary projects in regenerative and critical care medicine with industry, academia and international clinical experts. In 2013, he was an awarded a Wellcome Trust ISSF Junior Development Fellowship at the University of Leeds, UK. In 2016, he was appointed as an Assistant Professor (University Academic Fellow, tenure-track) in Basic Sciences Related to Dentistry and Musculoskeletal Disease at the University of Leeds. His primary research focus lies in the preclinical development of novel drug delivery technologies and advanced gene expression systems for non-viral in vivo gene therapy using a combination of approaches ranging from physical gene delivery, nanotechnology, synthetic biology, developmental biology and biomaterials science, ultimately aiming at translating these advanced therapies to the clinic for patient benefit. Dr. Feichtinger holds several international awards, has published in numerous peer-reviewed publications in high impact journals in the field of regenerative medicine and holds a granted European Patent on Matrix-assisted Sonoporation. He was previously the chair for TERMIS SYIS EU (2012-2015) and was as TERMIS European Council member (2015-2016). Dr Feichtinger is an interdisciplinary scientist and entrepreneur, founder of the biotech start-up Phycosera LTD, acts as an industry consultant in musculoskeletal tissue engineering and is a visiting lecturer at University College London (UCL).
Gerard Insley, BSc, PhD, MIEI, is a fly fisherman, scientist and inventor based in Ireland. Gerard has worked in the life science arena for over twenty five years focussing on biomaterials for skeletal repair. Gerard’s main passion is inspiring technical teams to solve the many difficulties facing clinicians in repairing replacing and augmenting fractured and compromised bone. With over a dozen biomaterials products commercialised and currently on the market Gerard continues to focus on developing disruptive biomaterials based solutions for unsolved clinical problems. These include the first load bearing biomaterial for hip revision applications BoneSave™, first Calcium Phosphate cement for screw augmentation trauma applications Hydroset™ and the first premixed calcium cement on the market iN3™. Gerard has worked with Howmedica, Stryker, CelgenTek and PBCBiomed and has co-founded 4 biomaterials companies with over 30 peer reviewed publications presentations and posters and more than a dozen commercialised patents in the field.
Gerjo van Osch (Female) studied Medical Biology at Utrecht University, the Netherlands and received a PhD from Nijmegen University based on her research on mouse models for osteoarthritis (1994). During her postdoc she started to focus on cartilage tissue engineering. She moved to Erasmus University Rotterdam in 1995 where she has set up her own research group. Gerjo is currently appointed as full professor of Connective Tissue Regeneration in the Departments of Orthopaedics and Otorhinolaryngology at Erasmus MC, University Medical Center Rotterdam. She is leading a research group of approx. 20 people. Her research aims at finding methods to regenerate cartilage with the use of stem cells, even in an inflamed environment. She is co-author on over 200 publications. Gerjo is involved in several national and European funded projects (also coordinating two Horizon2020 MSCA-ITNs) and is the chair of TERMIS-EU. She has served on the board of several (inter)national research societies such as the Dutch Society for Matrix Biology and the International Cartilage Repair Society and in editorial boards of scientific journals (a.o. Cartilage, Tissue Engineering, Journal of Tissue Engineering and Regenerative Medicine).
Gianluca Ciardelli (PhD) has a Master Degree in Chemistry summa cum laude, from the University of Pisa (1994). In 1997 he received the PhD in Natural Sciences from the Swiss Federal Institute of Technology (ETH) of Zurich on synthetic degradable polyurethanes for biomedical applications. From 2002 and 2004 he was assistant professor at the University of Pisa at the Department of Chemical Engineering, Industrial Chemistry, Materials Science. In December 2004 he joined the Department of Mechanics at the Politecnico di Torino as associated professor. He became Full Professor in Biomedical Engineering in 2011. Gianluca Ciardelli is coordinating a group of 15 people on average (Graduate Students and Post-docs, with an interdisciplinary background ranging from chemical, biomedical engineering and chemistry) carrying out research in the development of biomedical polymers and realisation of scaffolds for tissue engineering, drug delivery in nanomedicine, molecular recognition, tissue and organ 3D models. He is currently teaching at bachelor (Chemical Bioengineering), Master (Bionanotechnology), and PhD Level at Politecnico di Torino, where he is also Coordinator of the Ph.D course in Bioengineering and Surgical Medical Sciences. He has an h-index is 34 with around 4500 citations.
Gianni Ciofani (born on August 14th, 1982) is Associate Professor at the Polytechnic University of Torino, Department of Mechanical and Aerospace Engineering (Torino, Italy) and Senior Researcher at the Italian Institute of Technology (IIT), Smart Bio-Interfaces Research Line (Pontedera, Pisa, Italy). He received his Master Degree in Biomedical Engineering (with honors) from the University of Pisa, Italy, in July 2006, and, in the same year, his Diploma in Engineering (with honors) from the Scuola Superiore Sant’Anna of Pisa, Italy. In January 2010, he obtained his Ph.D. in Innovative Technologies (with honors) from the Scuola Superiore Sant’Anna. From January 2010 to August 2013 he was Post-Doc at the IIT, Center for Micro-BioRobotics @SSSA, where, from September 2013 to October 2015, he was Researcher in the framework of the Smart Materials Platform. In October 2015 he was appointed Associate Professor at the Polytechnic University of Torino, maintaining his research activity in IIT where he is currently Principal Investigator of the Smart Bio-Interfaces Research Line. His main research interests are in the field of smart nanomaterials for nanomedicine, bio/non-bio interactions, and biology in altered gravity conditions. He is coordinator or unit leader of many grants/projects, and in 2016 he was awarded a European Research Council (ERC) Starting Grant. Gianni Ciofani is author of more than 100 ISI papers (H-index 28, excluding self-citations), 3 edited books, and 14 book chapters. He delivered about 30 invited talks/lectures in international contexts and, for his research activity, he was awarded several national and international prizes. He serves as Reviewer for more than 100 international journals, as Editorial Board Member of the International Journal of Nanomedicine and of Advances in Nano Research, and as Specialty Chief Editor (Nanobiotechnology) for Frontiers in Bioengineering and Biotechnology. Gianni Ciofani is professor of Biomimetic Systems and Bionanotechnologies, and supervisor of several M.Sc. and Ph.D. students.
Giovanni Vozzi was graduated in Electronic Engineering in 1998 at the University of Pisa. In 2002 he got the PhD in Bioengineering at Polytechnical of Milan. From 2002 to 2006 he was Post-Doc working on development of microfabrication systems and on the realization and characterization of polymeric structures for application in the drug controlled release and in Tissue Engineering at research center “E. Piaggio of University of Pisa and at IMCB of CNR in Pisa. From 29/12/2014 at present he is associate professor in Bioengineering. In 30th March 2017, he has obtained national qualification as Full Professor in Bioengineering. He acts as supervisors of PhD students in Materials Engineering and Biomedical Engineering and coordinates the work of several undergraduate students and graduate fellows. He is member of Board of Directors of International Society of Biofabrication, of which he was founder, of IEEE and Of National Group of Bioengineering. His principal research interests are: 1) study and mechanical, chemical and cell characterisation of novel materials, principally obtained by waste materials and design of new methodologies of their functionalisation for application to Biomedical Engineering and to several areas of Industry; 2) development of new micro and nanofabrication techniques for application to Biomedical Engineering and to several areas of Industry; These scientific activities are demonstrated by more than 100 papers on International journal with high IF (h-index=23) 11 chapters on book and 21 patents. He is Editorial Board member of several journal and acts as reviewers for the most important journal in his research field. He was involved and coordinator in several national and European research projects. Actually he is the coordinator of BIOMEMBRANE project granted by M.ERANET network, and he is involved in UBORA: Euro-African Open Biomedical Engineering e-Platform for Innovation through Education, EU grant (H2020-INFRASUPP-2016-1 code: 731053).
Giuseppe Perale, Ph.D., is currently executive Vice-President of the Swiss medtech company IBI SA, which he funded with his colleague Dr. Gianni Pertici back in 2008. Within IBI, he teamed to the design, development, scale-up and complete testing up to human studies of an innovative composite biomaterial platform for bone regeneration. This innovative solution is among very first completely scaled-up composite biomaterials technologies that have been successfully translated not only into humans but also into market through out a complete technology transfer process. IBI recorded a safety clinical history of more than 50’000 patients grafted with its bone substituted and currently operates in 50+ Countries. Throughout the growth of the company, Prof. Perale kept his major scientific and coordination roles, mostly focused along all stages of research and implementation processes, particularly on clinical studies in orthopedic and oncologic applications. Since 2013, Prof. Perale also holds the chair of Biomaterials and Tissue Engineering at the University of Applied Sciences of Southern Switzerland. Currently he is also invited visiting Professor at the San Martino Hospital, by the Faculty of Biomedical Sciences of the University of Genova (Italy) and, among other appointments, he is member of the Steering Committee of the Swiss Tissue Engineering and Drug Delivery Competence Center. Author of more than a hundred scientific publications, inventor in three patent families, he is Editor in the Biomaterials and Medical lists of Woodhead Publishing (Elsevier Group), Cambridge (UK). Overall, his research interests are focused on regenerative medicine, tissue engineering and controlled drug delivery, grounding on his competencies on materials and technologies for biomedical applications and stem cells for translational applications. Following latest “nature inspired” philosophy, his research and experimental activities are devoted to theoretical investigations and development of feasible solutions for human tissues regeneration, aiming at achieving new knowledge and developing industrially-scaled processes for applicable new generation therapeutic approaches. From an engineering perspective, his research is based on resorbable materials such as formulated hydrogels, biopolymers and composite materials in general. From a technological point of view, his attention is mainly given to multidisciplinary approaches to solve biomedical process engineering and to develop sustainable medical devices. From a theoretic perspective, his main interests are towards principles of regenerative medicine, applied physical chemistry and transport phenomena with a particular attention to their implications in human physiology. From a clinical point of view, his research activities are focused on regeneration of injured spinal cord, bone regeneration and custom made solutions for personalized medicine. Orthogonal interest to such topics is given to mathematical modelling and to the development of computational supportive tools to couple with experimental evidences, fully embracing the “safety by design” paradigm.
Gowsihan (Gowsh) Poolgasundarampillai is a Birmingham Fellow in Biomaterials and Bioimaging at the University of Birmingham, School of Dentistry. His research activity is focused on biomaterials for tissue engineering and regenerative medicine. In specific, his group is actively developing novel organic-inorganic hybrid bioinks for 3D biofabrication. He is also focused on the production of bioactive glass and hybrid scaffolds for hard and soft tissue regeneration and their multiscale characterisation using advanced techniques. Gowsh was awarded his PhD in 2009 on ‘Development & characterisation of nanocomposites for bone tissue engineering’ from Imperial College London. His thesis was awarded the Matthey Prize. Gowsh has worked in several institutes (Nagoya Institute of Technology, Japan, Research Complex at Harwell and University of Manchester, UK) before securing the prestigious Birmingham Fellowship position in Dec 2017. Gowsh has over 13 years of research experience in biomaterials and X-ray imaging with 35+ publications and 30+ conference presentations. His group at present is 6 strong both at University of Birmingham and at Manchester consisting of clinician, material scientists, engineer and cell biologists. Until now several of his contributions to his research field have been extremely innovative, leading to two patent applications, 10 invited talks and a keynote.
Gráinne Cunniffe, PhD, completed her PhD at Queen’s University Belfast and the Royal College of Surgeons in Ireland in 2009, where she developed gene activated collagen-based scaffolds for bone tissue regeneration in Prof. Fergal O’Brien’s group. She then became a Senior Research Fellow at the Trinity Centre for Bioengineering working with Prof. Daniel Kelly, where she has conducted a wide range of investigations to develop biomaterial-based technologies for the repair of damaged musculoskeletal tissues, predominantly focused on the application of tissue specific extracellular matrix (ECM) as a material for regenerative approaches. She currently holds an adjunct Asst. Professor position at Trinity College Dublin and leads the collaborative 3D bioprinting regenerative medicine research on behalf of the 3D Printing Centre of Excellence, Johnson & Johnson. Her current research focuses on leveraging the developing area of 3D bioprinting to translate tissue engineering strategies for the repair and regeneration of numerous target tissues.
Graziella Pellegrini is Full Professor at the University of Modena and Reggio Emilia and Cell Therapy Program Coordinator at the Centre for Regenerative Medicine "Stefano Ferrari". She is also co-founder and R&D Director at Holostem Terapie Avanzate S.r.l. She graduated in Chemistry and Pharmaceutical Technologies (1988) and in Pharmacy (1889) at the University of Genova. She coordinated scientific teams in laboratories in different cities. Prof. Pellegrini is founding member of the International Ocular Surface Society and member of major scientific societies and international committees. She was awarded for a research on central nervous system, for research on ocular pathology and for research on urethra and received the ISSCR Award of Innovation in 2018 (with Michele De Luca). Author of 9 patents, 9 book chapters and over 70 peer reviewed publications in the major international journals, she was invited speaker or chairman in approximately 230 major international meetings on Stem Cells and Regenerative Medicine. Prof. Pellegrini is one of the two inventors of the technology for culture and transplantation of limbal stem cells for treatment of blindness due to corneal stem cell deficiency and collaborated to the orphan drug designation and European registration of the therapy. She developed other translational medicine protocols for treatment of third degree burns, depigmentation and is collaborating to a phase I clinical trial on gene therapy of epidermolysis bullosa. She is currently working with her team, on oral mucosa, urethra and airway epithelium.
Guoping Chen received his Ph.D. from Kyoto University in 1997 majoring in Biomaterials and did postdoctoral research until 2000. He became Researcher in 2000 and Senior Researcher in 2003 at Tissue Engineering Research Center, National Institute for Advanced Industrial Science and Technology, Japan. He moved to Biomaterials Center, National Institute for Materials Science (NIMS) as Senior Researcher in 2004 and was promoted to Group Leader in January, 2007. He was Principal Investigator and Unit Director of Tissue Regeneration Materials Unit from April, 2011 to March, 2015; Principal Investigator, Field Coordinator and Unit Director of International Center for Materials Nanoarchitectonics, NIMS from April, 2015 to March, 2017. He is also Professor of Department of Materials Science and Engineering, Graduate School of Pure and Applied Science, University of Tsukuba, Japan. His research interests include tissue engineering, polymeric porous scaffolds, nanobiomaterials, biomimetic biomaterials, nano/micro-patterning and surface modification. He has authored more than 280 publications and holds 18 issued patents. He has given more than 140 invited lectures at conferences. He is Associate Editor of Journal of Materials Chemistry B; Editorial Boards of Journal of Bioactive and Compatible Polymers, Tissue Engineering, Journal of Tissue Engineering and Regenerative Medicine, Regenerative Biomaterials and Biomedical Materials; Advisory Board of Biomaterials Science. He also serves as Member-at-Large of Tissue Engineering and Regenerative Medicine International Society’s Asian-Pacific Chapter and Director of Japanese Society for Biomaterials. He has been selected Fellow of the Royal Society of Chemistry in 2015 and the American Institute for Medical and Biological Engineering (AIMBE) in 2017.
Gwendolen Reilly, DPhil, obtained her PhD in bone biomechanics from the University of York UK in 1998. Since then she conducted research in the fields of bone mechanobiology and then biomaterials and tissue engineering in institutions in Switzerland (ETH) and the US (Penn State, U. Penn and UIChicago). In 2004 she obtained her faculty position at the University of Sheffield UK where she is now a Reader (Associate Professor) in Bioengineering working at the Department of Materials Science and the INSIGNEO institute for in silico medicine. Her research centres around two key themes; the effects of mechanical stimulation on differentiation and matrix formation by bone cells and the interactions between precursor bone cells and their biomaterial substrates. Recently her group has been focused on improving 3D tissue engineered models of bone to create humanised in vitro bone matrices that replicate important feature of bone matrix. We believe that accurate 3D models including bone’s complex, multiscale, hierarchical structure are needed to facilitate more relevant bone disease research than allowed by 2D culture or animal models. Gwen has published 74 papers and 6 book chapters in these areas with an h-index of 30. Gwen is the director of Training for INSIGNEO and Faculty of Engineering director for Equality Diversity and Inclusion. She is past president of the European Society for Biomechanics.
Hang Lin, PhD, is an Assistant Professor in Department of Orthopaedic Surgery at the University of Pittsburgh. He is also a member faculty in the McGowan Institute for Regenerative Medicine. Currently, Dr. Lin has published more than 40 peer-reviewed articles and 3 book chapters. He also holds 4 patents, with other 3 in pending. Dr. Lin’s research interests focus on the mechanistic study of articular joint diseases and the development of efficacious treatments. For example, he had developed micro-physiological joint tissues (microJoint) *in vitro*, which offer novel capabilities for investigating the physiology of joint organ and the pathogenic mechanisms of osteoarthritis (OA), and serving as a high-throughput platform to test potential drugs for OA treatment. He had also developed a method to apply visible light-based projection stereolithography (one type of 3D printing technologies) on live cell fabrication. These 3D printed constructs can be further activated through the inclusion of vectors carrying therapeutic growth factors (Gene-activated matrix/scaffold).
Hans Joerg Meisel, MD, PhD, in 1998 was appointed to the Berufsgenossenschaftliche Clinic in Bergmannstrost Halle/Saale as Director of the Clinic for Neurosurgery. Every year his team of 10 surgeons carries out a minimum of 1800 surgeries in the area of cerebral and spinal diseases. Since September 2008 Hans Joerg Meisel has been appointed as the Director of the Center of Neurosciences of the BG-Clinic Bergmannstrost Halle. Hans Joerg Meisels primary focus in spine surgery and research is for the last 20 years in degenerative spinal diseases. Starting as inventor and designer of spinal implants for the intervertebral space in cervical and lumbar in arthroplasty and fixation he developed 1995 the first biological disc repair transplantation system with autologus chondrocytes. Hans Joerg Meisel served as a PI for the first randomized clinical trial to study this regenerative approach (EuroDisc) after running all preclinical evaluations at Emory Spine Center, Atlanta. Together with his Atlanta group they continued the preclinical and clinical work in disc regeneration with adiposed derived mesenchymal stem cells. As a founding member Hans Joerg Meisel helped to start the European Technology Platform Nanomedicine (ETPN) for the European Commission. From 2003 to 2006 Hans Joerg Meisel served AOSpine Europe as a founding member and to develop a new teaching and course platform as a deputy on the neurosurgical side. (Intervertebral Disc Course Davos, 2005; Strasbourg Course 2006; Cervical Course Palma de Mallorca, 2006). In 2005 Hans Joerg Meisel co-founded the Translation Center for Regenerative Medicine at the University of Leipzig and supported there as an Executive Board member the preclinical affairs mentoring since the beginning 4 major spinal projects with the focus in regenerative disc repair and biomaterials financed by the German Ministry of Research (BMBF). In 2005 Hans Joerg Meisel founded the European Network for Regenerative Medicine Regenerate Europe which integrates 10 countries of the European Union that carries out research in the area of Regenerative Medicine and organized the Biospine Meetings (2002, 2007, 2010, 2015) and Regulatory Workshops for ATMPs and animal modeling (2010, 2012, 2014). In 2007 Hans Joerg Meisel was appointed by the Vrije University of Amsterdam to become a Visiting Professor at sponsored the Department of Orthopedic Surgery for the coordination of international research projects and the development of the European Master Degree in Regenerative Medicine. From 2011-2015 he was chairing the EU COST project “Namabio -From nano to macro biomaterials (design, processing, characterization, modelling) and applications to stem cells in regenerative orthopaedic and dental medicine” including 250 members in nanomaterial research and clinical application. In 2013 he became an Honorary Professor in the Department for Health Sciences and Biomedicine at the Donau-University Krems (Austria). In 2013 he became an elected member of the AO Spine Knowledge Forum Degenerative and Biologics. In 2014 he was elected as chair of the European Technology Platform Nanomedicine (ETPN) Working Group of Nanotechnologies for Regenerative Medicine. In 2017 he was re-elected for the same position.
Hasan Havitcioglu is a Professor at the Department of Orthopedics and Traumatology, Faculty of Medicine at Dokuz Eylul University, Izmir, Turkey. He is also the head manager of Biomechanics Department at faculty of Health Sciences and Bone - Cartilage Tissue Biotechnology Application and Research Center (KEKDOB) at Dokuz Eylul University. He received his undergraduate degree (1980) in medicine from Ege University. He received his specialization of medicine (1985) from Dokuz Eylul University Orthopedics and Traumatology Department. He went to the Mayo Clinic to perform academic studies on Orthopedic Oncology. He became an Associate Professor (1993) and a Professor (1999) at Dokuz Eylul University Orthopedics and Traumatology Department. He established the Department of Biomechanics (2005) and Bone - Cartilage Tissue Biotechnology Application and Research Center (KEKDOB) (2011). He is the head of the Department of Orthopedics and Traumatology since 2010. His research interests include the study of Tissue Engineering in Orthopedics and Biomechanics. He has more than 20 patented inventions in these research fields.
Hassan Niknejad, PharmD, PhD, is academic professor at School of Medicine, Shahid Beheshti Medical University and founder and ex-chair of School of Advanced Technologies in Medicine. Dr. Niknejad has published more than 100 articles in peer-reviewed high-rank journals in the field of stem cell and tissue engineering. In the last 10 years, his area of research was focused on biology and applications of Placenta, as a source of stem cells and also natural biomaterial for tissue engineering and application of microfluidic system for encapsulation of stem cells. Dr. Niknejad focused on regenerative potentials of amniotic epithelial and mesenchmal stem cells in different clinical situations such as vascular surgeries, neurodegenerative diseases, wound healing and cancer. Moreover, the potential of amniotic cells to restrict the growth of tumor cells through inhibition of angiogenesis and induction of apoptosis was showed in his research team. In addition, the amnion was administered as scaffold for vascular tissue engineering in which the ability of the AM was examined to be a substrate for delivery of endothelial cells and also the vein constructed from amnion was transplanted as jugular vein conduit of animal model in his research team. He has registered ten works as patents. His three patented inventions in the field of wound healing and osteoarthritis recently led to high commercial transactions in Asian healthcare system.
Hedwig Kruitwagen, DVM, PhD, is a resident in companion animal internal medicine (ECVIM-CA) at the Faculty of Veterinary Medicine, Utrecht University, The Netherlands. She did a PhD in liver stem cell biology and liver regeneration in dogs, cats and humans. In the research lab of the Department of Clinical Sciences of Companion Animals, Hedwig was involved in establishing organoid cultures from dog and cat liver (Nantasanti et al. 2015; Kruitwagen et al. 2017). Organoids are defined as ‘structures resembling an organ’ and are a 3D adult stem cell culture system developed in the lab of Hans Clevers (Hubrecht Institute). Hedwig performed a transplantation study of autologous canine liver organoids in dogs with genetic copper storage disease. A second research interest is the culture of feline liver organoids and their application as preclinical disease model for hepatic steatosis. An important focus in all research projects is translational medicine, both from bench to bedside as well as between veterinary and human medicine.
Heidi Andrea Declercq, PhD, studied Biomedical Engineering and received her PhD (*In vitro* models for bone tissue engineering) in Medical Sciences from Ghent University, Belgium, in 2005. As postdoctoral researcher, she was involved in the evolution of top-down (scaffold-based) to bottom-up (developmental inspired) tissue engineering strategies. She worked on several effects of (printed) scaffold parameters to enhance cellular differentiation. She studied expansion and differentiation of human adult and embryonic stem cells. But later on, she focused to modular tissue engineering by at random assembling of stem cell-seeded microcarriers and spheroids. In 2017 she became head of the Tissue Engineering group with embedded the Bioprint Facility. Her group, FACOMTI, aims to biofabricate complex and vascularized tissues via hybrid technologies. Hybrid bioprinting will combine aspects of top-down and bottom-up engineering and will have synergistic effects on fabricated tissues (maturation, mechanical strength,…). Tissue-specific or vascular spheroids are fabricated in high throughput and bioprinted in combination with smart biomaterials. H. Declercq is involved as lecturer (Cell & Tissue Culture, Biomaterials, Tissue Engineering) for bachelor and master students Biomedical Sciences and Biomedical Engineering. She is the founder of GATE, Gent Alliance for Tissue Engineering, aiming to unite all research groups at UGent involved in the field of tissue engineering and with different expertises (modelling, smart biomaterials, microfluidics, stem cells, …), leading to bridge the gap in healthcare.
Heinz Redl, PhD, is Director of the Ludwig Boltzmann Institute for Clinical and Experimental Traumatology, Vienna, Austria. He has a background in biochemistry with almost 40 years’ experience in trauma and regenerative medicine research. As director of the Ludwig Boltzmann Institute he works within the main trauma research center of AUVA, representing 7 trauma and 4 rehabilitation centers, and holds the position of Associated Professor at the Institute for Chemical Engineering, Technical University Vienna. In 2006, he founded the Austrian Cluster for Tissue Regeneration, which includes work groups from academia and industry with multiple research targets. To further enhance industry cooperation he founded the company Trauma Care Consult which specializes in preclinical research and covers products registration at the FDA and EMA. In 2014 he co-founded the spin-off company Liporegena, and in 2017, MorphoMed. Prof. Redl has organized many conferences in the field of regenerative medicine such as the World Congress for Tissue Engineering and Regenerative Medicine (TERMIS) 2012 and the Bernard Wiggers Congress in 2017. He holds positions in several societies, such as Chair of TERMIS-EU and is member of multiple editorial boards. He was awarded the 2001 Lorenz-Böhler-Medaille, the 2012 Karl Landsteiner Memorial Lecture (DGTT), the 2013 Wilhelm-Exner-Medaille. Furthermore, he was awarded “International Fellow of Tissue Engineering & Tissue Regeneration” in 2015 and “International Fellow of the European Alliance for Medical and Biomedical Engineering and Science” in 2018. He is co-developer of the fibrin sealant system, developer of surgical devices in current clinical use and many collaboration projects with major industry partners. He has written over 540 papers and holds more than 15 patents/patent submissions.
Hélène Autefage, PhD, got her doctoral degree in Biomaterials sciences from the University of Toulouse in 2009. Her PhD project focused on the development, and characterisation, in vitro and in vivo, of a biomimetic calcium phosphate bone substitute. This work led to a patent, licencing and commercialisation of the bone substitute. She joined Prof. Molly Stevens group at Imperial College London as research associate. For her post-doctoral research, she worked on the development and characterization of an osteochondral construct with controlled architecture, mechanical properties and biological activity, and investigated the influence of the ionic composition of bioactive glass bone substitutes on cellular processes and bone formation. Since 2016, Hélène is Project Leader in Prof. Stevens satellite group in the Division of Biomaterials at Karolinska Institutet in Stockholm. Hélène’s research aims at better understanding how materials’physical-chemical properties influence cell responses and tissue characteristics. Her current research takes advantage of non-discriminative – omics technologies and in-depth material and tissue characterisations to gain knowledge on cell and tissue/material interactions.
Helene Roelofs is a clinical translational researcher and supervisor of translational research at the Leiden University Medical Centre in The Netherlands. She was initially trained as a chemist and received a PhD in Molecular Genetics (1992). Dr. Helene Roelofs has worked as a fundamental researcher in various oncology-related fields at Lineberger Cancer Research Centre (UNC, Chapel Hill, USA), Erasmus University Rotterdam (The Netherlands) and Leiden University Medical Centre. Here, she embarked in 2002 on a career as translational researcher aiming to utilize the newly discovered immunomodulatory properties of mesenchymal stromal cells (MSC) for the benefit of patients. She has been an active participant in various national and EU funded project; EU FP7 REDDSTAR which investigated the potential of a novel stromal cell therapy for the treatment of various complications of diabetes mellitus and developed a cell therapy product for clinical investigation in patients with diabetic ulcers, EU FP7 REACH which developed and tested a closed bioreactor system for environmentally controlled and automated cell expansion, EU H2020 RETHRIM which includes a phase III clinical trial to investigate an MSC product for efficacy, effectiveness and safety in patients with steroid refractory GvHD, and EU H2020 NEPHSTROM, which develops a novel stromal cell therapy for diabetic patients suffering from progressive kidney disease. As a translational researcher Dr. Helene Roelofs brought multiple cell therapies products to phase I, II and III clinical testing. Currently these products have been/are being tested in a variety of patient groups including kidney transplantation, stem cell transplantation, GvHD, diabetic, COPD, myocardial infarct and Crohn’s patients.
Heli Skottman, PhD, joined Tampere University, Finland in 2005 having worked as a postdoctoral research fellow in Karolinska Institute, Sweden and University of Turku, Finland. Dr. Skottman holds M.Sc. in applied zoology and a Ph.D. in molecular animal biotechnology in University of Eastern Finland. In addition she has educated herself in Biobusiness program at Turku School of Economics, Finland. Dr. Skottman is currently Associate Professor in Faculty of Medicine and Health Technology at Tampere University, independent group leader and responsible professor for Master of Science in cell technology program. Dr. Skottman has over 16 years’ experience on establishment, culture and differentiation of human pluripotent stem cells (hPSC). Last 11 years she has devoted herself in eye research targeting already from the early phases of research towards clinical applications in ophthalmology. Currently her research focus on retinal and corneal diseases, developing hPSC based tools for disease modeling, drug discovery and cell transplantation. In addition, she has experience on intellectual property strategy, licensing of stem cell products and establishment of a spin-off company. She has co-authored several patent applications and has over 90 peer reviewed scientific publications in area of biotechnology and human stem cell research. She is also active peer reviewer in many journals as well as a member of editorial board in Scientific Reports.
Hyung Joon Cha received his PhD in Chemical Engineering from Seoul National University in 1995. From 1996 to 1998, he was the Postdoctoral Associate in University of Maryland Biotechnology Institute, USA and the Assistant Research Professor of Department of Chemical Engineering at University of Maryland, College Park in 1998-1999. He joined POSTECH in 1999. His area of interests includes protein-based biomaterials, tissue and biomedical engineering, and biosensors. He has published ~200 peer-reviewed research papers and holds more than 90-registrated patents. Currently, he is the SeAH Chair Professor of POSTECH and the Director of Marine BioMaterials Research Center funded by the Ministry of Oceans and Fisheries, Korea through recognition of his prominent works on mussel-derived adhesive biomaterials for tissue and biomedical applications. He is also the co-founder and Chief Technology Officer of Nature Gluetech Co., Ltd for technology commercialization of mussel adhesive protein as an innovative medical bioadhesive. His work has been recognized by many awards, selectively including a Korea Engineering Award of the Korea President, Inventor of The Year Award, a 2020 Future 100 Best Technologies and Researchers Award, a 2012 National R&D 100 Best Researches Award, and a Song-Gok Science and Technology Award.
Ilida Ortega Asencio is a Lecturer in Materials and Manufacturing at The Bioengineering and Health Technologies Group at The University of Sheffield. During her research career, she has gained extensive experience working at the interface of materials science and biology, particularly in the design, characterisation and in vitro testing of biomaterial devices for regenerative medicine. Following her PhD at The University Miguel Hernandez of Elche (Spain, 2010), she moved to the UK in order to establish her academic career. She gained postdoctoral experience through different positions; firstly, she worked as a PDRA in a 1-year Wellcome Trust funded project (2011) and following this she was awarded a 2-year competitive EPSRC E-TERM Landscape Fellowship (2012-2014). Her postdoctoral experience was focused on the development of innovative membranes for corneal repair, specifically, her work was focused on the design and manufacture of corneal membranes equipped with 3D microenvironments and in their in vitro evaluation. Ilida is a member of the £6.9m EPSRC Centre for Innovative Manufacturing in Medical Devices (MeDe Innovation) and one of the founders of the MeDe Innovation Early Career Research Forum where she acted as delegate for The University of Sheffield. Ilida also acts as a Core-Facilities Lead for Materials at her Department and as a PGR-Coordinator for the Bioengineering and Health Technologies Group at Sheffield.
Ineke Slaper-Cortenbach is currently working as a biomedical consultant in the field of (stem) cell therapy and regenerative medicine. As a project manager, she recently completed the transition of the Sanquin Cord Blood Bank from Leiden to Amsterdam. She has also been working for almost 3 years at ZonMW (the Netherlands Organisation for Health Research and Development) in the Hague, the Netherlands, where she was the programme manager responsible for funding projects in ‘Translational research and international programmes’. From 2000 – 2016, she was the head of the Cell Therapy Facility in the UMC Utrecht with more than 30 years' experience as a laboratory director in cell therapy. She is an internationally well-known leading authority in regulatory affairs of cellular products. Her expertise is reflected by taking the lead in multiple national and international organizations (JACIE, ISCT etc). She is chairing the Board of Directors of ICCBBA, the organization that is managing and promoting the ISBT 128 international information standard for use in transfusion and transplantation. She also is the chair of the ICCBBA Regenerative Medicine Technical Advisory Group. In the Netherlands, she is a member of the Advanced Therapy Medicinal Products (ATMP) committee of the Medicines Evaluation Board.
Insung S Choi is Professor of Chemistry and of Bio and Brain Engineering at KAIST, Korea, and the Director of the Center for Cell-Encapsulation Research (Creative Research Initiative; 2012-). He obtained his BS and MS degrees in Chemistry at Seoul National University in 1991 and 1993, and did his PhD degree in Chemistry at Harvard University in 2000 under the supervision of George M. Whitesides. After postdoctoral work with Robert Langer at the Department of Chemical Engineering of MIT, he joined the faculty at KAIST in 2002. He was awarded KCS-Wily Young Chemist Award (2003), Thieme Journal Award (2003), Presidential Young Scientist Award (2004; KAST), and JANG SEHEE Research Achievement Award (2013; KCS). His research interests include biomimetic science and neurochemistry. He has published over 250 peer-reviewed papers (H-index > 55). He is the editorial board member of Chemistry-An Asian Journal (Wiley-VCH), ChemNanoMat (Wiley-VCH), Materials Today Bio (Elsevier) and Polymers (MDPI), and the editorial advisory board member of Advanced Healthcare Materials (Wiley-VCH).
Ipsita Roy, PhD, is an expert in Microbial Biotechnology, Biomaterials and Tissue Engineering. She is currently a Professor at the Faculty of Science and Technology, University of Westminster, London. She was awarded the Inlaks Scholarship to study for her Ph.D. at the University of Cambridge. Her postdoctoral work was at the University of Minnesota, USA. Subsequently, she has been at the University of Westminster since 2000 and leads the Applied Biotechnology Research Group. She has published over 100 papers in high ‘Impact Factor’ journals such as Biomaterials, Biomacromolecules, Journal of Royal Society Interface. Her group is currently focussed on the production of novel polyhydroxyalkanoates (PHAs), a group of FDA-approved natural polymers and their characterisation. She is an editor of the Journal of Chemical Technology and Biotechnology (JCTB). She is on the BBSRC, EPSRC, NSERC, Canada, ERC, NSFC, China, MUIR grant-reviewing panels. Her work has been funded by the EPSRC, EU, DuPont and WESTFOCUS, London. Ipsita was the Scientific Coordinator of a large EU project, REBIOSTENT, worth 4.9 million Euros and is currently coordinating a H2020 project HYMEDPOLY, worth 3.5 million Euros. She was work package leader in NEURIMP, worth 4.4 million Euros. Recently she has initiated working on another H2020 project POLBIOSKIN worth 3 million Euros. All four projects involve the use of PHAs for medical applications, drug eluting biodegradable stents, nerve guidance conduits, antibacterial polymers and wound healing.
Irem Bayindir-Buchhalter, Associate Editor for the *Advanced* family of journals, studied Molecular Biology and Genetics in the Middle East Technical University, Ankara. She focused on the hematopoietic differentiation of embryonic stem cells, during her MSc at Heidelberg University and the German Cancer Research Center (DKFZ). She obtained her PhD working on adipose tissue plasticity and metabolic homeostasis at the same institute. Her critical approach to research and strong interest in continuous learning led Irem to apply for a position in scientific editing at Wiley-VCH. She is based in Weinheim working as a peer review editor for *Advanced Functional Materials, Advanced Healthcare Materials* and *Small*.
Iris Ribitsch qualified as a veterinarian from the University of Veterinary Medicine Vienna in and undertook further scientific training as a Doctorate Candidate at the Clinic for Orthopedics in Ungulates, University of Veterinary Medicine Vienna culminating in a Dr. degree for her studies on the “Correlation of specific synovial fluid quality parameters with the degree of cartilage degeneration in horses”. Iris Ribitsch is currently working as Senior Post Doc and deputy head of the Veterinary Tissue Engineering and Regenerative Medicine lab of Prof. Florien Jenner at the University of Veterinary Medicine Vienna/ Equine clinic. Her main research focus is on equine cartilage, tendon and meniscus regeneration. Within that scope she is working i.a. in a consortia project comparing fetal regeneration and adult repair in order to find key factors which may be used to trigger tissue regeneration in an adult environment. Before her current engagement at the University of Veterinary Medicine Vienna she divided her time equally between a position as Post Doc at the Translational Centre for Regenerative Medicine, Leipzig (Supervisor Prof. Walter Brehm) and a position as International Product Manager at a human private/public cord blood bank. From 2007 to 2009 she worked as Project Manager and research assistant in a company offering stem cell therapy for equine tendon injuries and cord blood banking for humans. Iris is Chair of the TERMIS veterinary subgroup. She is also a European Expert and Member of CVMP (Committee for Medicinal Products for Veterinary Use) Interested parties as well as ADVENT (Ad Hoc Expert Group on Veterinary Novel Therapies) topic group at EMA (European Medicines Agency) as well as a steering committee member of the Viennese “Platform for advanced cellular therapies”.

![Iris Ribitsch](image-url)
Ivan Martin studied Biomedical Engineering at the University of Genova where he obtained his PhD in 1996. Between 1996 and 1999 he was a postdoctoral associate at Harvard/MIT. He joined the Department of Biomedicine at the University of Basel in 1999 as Director of the Tissue Engineering Research Group. In 2007 he was appointed Professor for Tissue Engineering. From 2004 to 2009 he was the first Chair of the European section of the Tissue Engineering Regenerative Medicine International Society (TERMIS). He is currently member of the editorial boards of 5 international journals and of the ‘Mesenchymal stem cell committee’ of the International Society for Cellular Therapy (ISCT). In 2018 he was elected as member of the Swiss Academy of Medical Sciences. His group includes scientists from the biological, engineering and clinical fields, dedicated to develop solid scientific basis for innovative translational strategies in regenerative medicine. He is author of more than 250 peer-reviewed papers on international journals (H-index of 82) and inventor on 10 patent applications. The developed science and technology have been translated into clinical trials for cell-based cartilage and bone repair, and into the founding of a spin-out company for the commercialization of tissue culture bioreactors (Cellec Biotek AG).
**Ivo Lambrichts** is a dentist-scientist who has been exploring the field of oral biology with special interest for innervation, microscopy and ultrastructural imaging of pulpal tissue and mineralized oral tissues. He received a PhD grant from the Belgian National Fund for Scientific Research to study the innervation of the periodontal ligament and epithelial rest of Malassez. After his PhD he contributed to European COST actions B8 on odontogenesis and COST action B23 on oro-facial development as an expert and manager. For the last 12 years his laboratory has contributed to the field of dental stem cell research. His group was supported by several research grants by the Fund for Scientific research. They worked on different isolation techniques and were successful in differentiation experiments and in vivo experiments. Their routine experiments are the transwell migration tests, wound healing tests, tube formation, CAM assay (used for the first time on DPSC’s), stem cell labelling and bioluminescence and HR-MRI tracking of dental stem cells. They proved the DPSC’s to be able to differentiate toward Schwann cells, toward functional neurons. In 3D printed hydroxyapatite scaffolds they were able to produce osteodentin and blood vessels engineered by DPSC’s. In 2012 he contributed based on his expertise to the construction and implantation of the world first 3D printed custom made full jaw in titanium via SLM technology in an 83 years old patient. Very recently the use of autologous biomaterials such as L-PRF was introduced in dental stem cell research. His lab contributes also to regenerative endodontic procedures.
Janina Burk, Dr. med. vet., is specialized in Veterinary Regenerative Medicine and works on translational research into mesenchymal stromal cell-based tendon therapies. She has studied and worked at the Justus-Liebig-University, Giessen, Germany, the University of Leipzig, Germany, the University of Bristol, UK, and the University of Natural Resources and Life Sciences (BÖKU) Vienna, Austria. She is Principle Investigator at the Saxon Incubator for Clinical Translation (SIKT), University of Leipzig, since 2013.
Jay Dudhia obtained his PhD in Molecular Biology from University of London and then joined the Kennedy Institute of Rheumatology (London) to research the molecular and ageing aspects of articular cartilage. He later moved to the Royal Veterinary College (London) where he runs the Tendon and Cartilage Biology research group, with interests focused on the ageing and pathogenic mechanisms of equine tendinopathies and human osteoarthritis. He has established in vitro and in vivo models of tendon injuries and a key area is to investigate the therapeutic potential of mesenchymal stem cells (MSCs) for tendon repair and cardiac stem cells for heart disease. Following the pioneering studies at the RVC for the clinical use of MSCs for tendon injuries in the horse, he has established a Veterinary Medicine Directorate approved stem cell laboratory for clinical grade MSCs for the equine and dog clinics. He has previously been a Committee and Board Member and honorary treasurer for the British Society for Matrix Biology, and recently co-edited a special issue on Stem Cells across Species for Cytometry Part A as associate editor. He is Editorial Board Member of Nature Scientific Reports and serves on the panel of experts of Versus Arthritis (Arthritis Research UK). Jay holds an Honorary Senior Lectureship at University College London.
Jennifer H Elisseff is the Morton Goldberg Professor and Director of the Translational Tissue Engineering Center at Johns Hopkins Department of Biomedical Engineering and the Wilmer Eye Institute with appointments in Chemical and Biological Engineering, Materials Science and Orthopedic Surgery. She was elected a Fellow of the American Institute of Medical and Biological Engineering, the National Academy of Inventors, and a Young Global Leader by World Economic Forum. In 2018, she was elected to the National Academy of Engineering and National Academy of Medicine. Jennifer received a bachelor’s degree in chemistry from Carnegie Mellon University and a PhD in medical engineering from the Harvard–MIT Division of Health Sciences and Technology. Later she was a Fellow at the National Institute of General Medical Sciences, Pharmacology Research Associate Program, where she worked in the National Institute of Dental and Craniofacial Research. She has published over 200 papers, book chapters, and patent applications and received a number of awards including the Carnegie Young Alumni Award and in 2002 she was named by MIT Technology Review as a top innovator under 35. Jennifer’s research focus is the development of biomaterials for regenerative medicine applications in orthopedics, plastic and reconstructive surgery, and ophthalmology. She is now studying Biomaterials-directed Regenerative Immunology and the role of the adaptive immune system in tissue repair. She is committed to the translation of regenerative biomaterials and has founded several companies and participates in several industry advisory boards.
Jens M Kelm, PhD is a biotech executive and co-inventor of 3D microtissue technology with more than 15 years of experience in Biotech. He got his PhD at the Institute of Biotechnology at the ETHZ followed by a research associate position at the University Hospital Zürich. After two years he became the scientific director of the Competence Center Applied Biotechnology and Molecular Medicine (CABMM) at the University of Zürich. He is a co-founder of InSphero AG where he served as CSO/CTO as well as chairman of the Board of Directors. Currently he is co-founder and CEO of PreComb Therapeutics AG applying 3D tissue engineering technologies to discover novel drug combinations. Jens has generated 10 patents/applications, published more than 50 scientific publications focusing on the development and implementation of 3D models in drug discovery and regenerative medicine. and is also co-founder and committee member of the competence center for Tissue engineering for Drug Development and substance Testing (TEDD).
Jeroen Rouwkema, PhD, got his PhD in Regenerative Medicine from the University of Twente, the Netherlands, in 2007. He received his PhD under the supervision of Prof. Clemens van Blitterswijk and gained further experience at MIT (Prof. Bob Langer), Keele University (Prof. Alicia El Haj) and Harvard Medical School (Prof. Ali Khademhosseini). He is currently an Associate Professor at the Department of Biomechanical Engineering, University of Twente, where he leads his own group focusing on vascularization of engineered tissues. He is a tissue engineer with an extensive experience in this field, having focused on the vascularization of skeletal muscle, bone, and cardiac muscle tissue. To optimize the organization and maturation of vascular networks, he combines tissue engineering technology with mechanical and chemical stimulation, computational modeling and biofabrication. He has published in numerous top-tier journals, including Nature Biotechnology, Advanced Materials, and PNAS. He has received several personal scholarships, including a VENI scholarship (2011-2014), a Marie Skłodowska-Curie International Outgoing Fellowship (2014-2017) and an ERC Consolidator Grant (2017-2022). In 2017 he received the TERMIS EU Robert Brown Early Career Principal Investigator Award in recognition of his achievements.
Jeroen van den Beucken, PhD, is Associate Professor ‘Translational Cell-Material Interactions’ in the Regenerative Biomaterials group at Radboudumc, Nijmegen, the Netherlands. Additionally, he is appointed as Principal Investigator within the Radboud Institute for Molecular Life Sciences (RIMLS), Radboud University, Nijmegen, the Netherlands. With the field of (bone) regenerative medicine as the revolutionary source for novel treatment modalities in the clinic, he anticipates that particularly knowledge on cell-material and cell-cell interactions will be instrumental for effective future bone defect treatments. As such, his research has focused on coculture systems for enhanced bone regeneration, using mesenchymal stromal cells and several other cell types (e.g. endothelial and inflammatory cells). Over the last few years, he has started to exploit the concept of bone remodeling, directing his current research on the role of osteoclasts for bone regenerative applications. To date, he has (co-)authored >130 peer-reviewed scientific papers, is involved in clinical translation of novel biomaterials, and received the ZonMw International Breakthrough Award (2014) for his work on intra-operative construct preparation for bone regenerative applications.
Jérôme Guicheux (48 yo) has received his PhD in cell biology and health sciences in 1997 at the Nantes University school of dental medicine. He was then a research associate in the internal medicine and rheumatology department of the University Medical Center of Geneva (Switzerland) from 1997 to 2001. He was finally recruited as a tenured junior research scientist by the French national institute for health and medical research (INSERM) and assigned to the Nantes University in 2001. JG has been promoted and appointed INSERM Research Director/full tenured professor in 2008. He is currently director of the INSERM research Centre RMES « Regenerative Medicine and Skeleton » (INSERM U1229, 100 people, Nantes, France; http://www.rmes.univ-nantes.fr/home/) and the scientific director of the SC3M core facility (electron Microscopy, Microcharacterization and functional Morpho-histology and imaging) of the François Bonamy Health Federative Research Institute (UMS INSERM-CNRS 016/ FED 4203). In 2014, Jerome Guicheux was appointed as the national coordinator of the French network dedicated to osteoarthritis and joint aging (ROAD). In 2015, he was elected President of the French society of mineralized tissue biology (SFBTM). JG is an elected member of the board of directors of OARSI, the osteoarthritis research society international. JG has coordinated 5 pluri-annual programs from the French national research agency (ANR) and served as WP/task leader in several European projects from FP7, FP8 and H2020. In 2011, he received the “Victor and Erminia Mescle” award from the French Foundation for Medical Research. He has authored (updated July 2018) more than 180 indexed publications (H-index 45, total citations 5550, source ISI web of knowledge) and 8 patents. His research focuses on the pathophysiology of osteoarthritis and regenerative medicine of the skeleton with particular emphasis on the development of stem cells and biomaterials for the repair of cartilage and intervertebral disc. ISI WOK Researcher ID F-7767-2013; ORCID 0000-0003-2754-3024;
Jiandong Ding is the director of The State Key Laboratory of Molecular Engineering of Polymers, and distinguished professor at Department of Macromolecular Science, Fudan University. He obtained his BS from School of Life Sciences in 1988, MS from Department of Materials Science in 1991, PhD from Department of Macromolecule Science in 1995 at the same university, Fudan University. He did his postdoctor research in Department of Materials Science, University of Cambridge. He is leading a biomaterials group covering biodegradable polymers, release carriers of drugs, and regenerative medicine. He was awarded as First-rate Prize of Natural Science Research by Ministry of Education. He is a Chang-Jiang Scholar selected by Ministry of Education and a Distinguished Young Scientist by Natural Science Foundation. He was a chief scientist of a 973 program from Ministry of Science and Technology, and is currently leading a National Key R&D Program of China about biomedical materials. Dr. Ding is a fellow of International Union of Societies of Biomaterials Science and Engineering. He serves as a member or advisory member of Editorial Board of some international academic journals such as Regenerative Biomaterials, Macromolecules, ACS Biomaterials Science and Engineering.
Jiang Chang, Shanghai Institute of Ceramics, Chinese Academy of Sciences, Fellow of International Union of Societies for Biomaterials Science and Engineering (FBSE), Fellow of Royal Society of Chemistry (FRSC), and Fellow of American Institute of Medical and Biological Engineering (AIMBE). Ph.D in 1991 in Chemistry from the Technical University of Darmstadt in Germany. Post Doctoral Research Fellow at the Medical University of Luebeck in Germany (1991-1993); Research fellow at the School of Medicine, University of Auckland in New Zealand (1993-1997); Research Assistant Professor in the Medical School at New York University (1997-1999); Research scientist at Johnson&Johnson (1999-2000); Professor and founder of the Biomaterials and Tissue Engineering Research Center of the Shanghai Institute of Ceramics. Professor Chang is the vice president of the Interdisciplinary Research Society for Bone and Joint Injectable Biomaterials. He is also an associate editor of the Journal of Materials Chemistry B, and International Editorial Advisory Board member of Biomaterials. His research focuses on bioactive materials for tissue regeneration and tissue engineering and the mechanisms of the interaction between biomaterials and cells. Professor Chang has over 380 scientific papers published in international peer-reviewed scientific journals and 70 patents in the field of biomedical materials.
Jianwu Dai completed his PhD from Duke University and postdoctoral studies from Harvard Medical School. He is now the Director of the Center for Regenerative Medicine, Institute of Genetics and Developmental Biology at Chinese Academy of Sciences. He has developed functional collagen scaffolds with growth factors and stem cell binding abilities which could actively induce a variety of tissue regeneration. He has published over 200 papers in reputed journals in the field of regenerative medicine and has been serving as an editorial board member of Biomaterials. He has pioneered several tissue regenerative clinical studies including spinal cord injury repair.
João Borges graduated and received his PhD in Chemistry from the University of Porto (Portugal) in 2008 and 2013, respectively. From 2013-2018, he was a postdoctoral fellow at University of Minho (Portugal) and University of Aveiro (Portugal). Currently, he is a Junior Research Fellow and Principal Investigator of a R&D project at CICECO – Aveiro Institute of Materials, University of Aveiro, with an individual contract supported by the Portuguese Foundation for Science and Technology (FCT). His research interests include the molecular design and development of supramolecular biomaterials, based on the bottom-up self-assembly strategy and Layer-by-Layer assembly technology, for biomedical and healthcare applications. In particular, he has been developing supramolecular functional biomaterials, by resorting to natural-origin polymeric materials and peptides, to be used as bioinstructive matrices to control the behavior of bioactive molecules and cells and as platforms for controlled drug delivery. He has published original full research articles and review papers in high-ranked international peer-reviewed scientific journals, and has been an ad-hoc reviewer for several international refereed journals. He has been also actively involved in the preparation, implementation and management of several grant proposals funded at national and European levels, in teaching, mentoring, science outreach and public engagement activities, as well as in chairing and organizing international scientific conferences.
João F. Mano is a Full Professor at the Chemistry Department of University of Aveiro, Portugal, and director of the COMPASS Research Group, formed in 2016 in the Associated Laboratory CICECO – Aveiro Institute of Materials. He is the director of both Master and Doctoral Degrees in Biotechnology at the Univ. of Aveiro. His research interests include the use of biomaterials and cells towards the progress of transdisciplinary concepts to be employed in regenerative and personalised medicine. In particular, he has been applying biomimetic and nano/micro-technology approaches to polymer-based biomaterials and surfaces in order to develop biomedical devices with improved structural and (multi-)functional properties, or in the engineering of microenvironments to control cell behaviour and organization, to be exploited clinically in advanced therapies or in drug screening. João F. Mano is author of 580+ papers in international journals (19200+ citations, $h=69$, WoS). He has been part of a series of scientific societies and editorial boards of more than 7 well established international journals. João F. Mano has received different honours and awards: (i) fellow of the IUPAC (International Union of Pure and Applied Chemistry) since 2004; (ii) the Stimulus to Excellence Award by the Portuguese Minister for Science and Technology in 2005; (iii) the Materials Science and Technology Prize, attributed by the Federation of European Materials Societies (FEMS) in 2007 (iv) UNESCO Chair on Biomaterials attributed in 2008 from the University of Havana (Cuba); (v) the major BES innovation award in 2010 (at that time, one of the most recognised innovation prize in Portugal); (vi) recipient an Advanced Grant from the European Research Council (ERC-AdG), in 2015; (vii) received the title of Professor@Lorraine from the University of Lorraine, France, in 2018; (viii) recipient a Consolidator Grant from the European Research Council (ERC-AdG), in 2018.
Jochen Salber received his diploma in chemistry from the RWTH Aachen University in 1995. While preparing his PhD thesis in the biomaterials field he started his studies in medicine. In 2001, he achieved his PhD from the RWTH Aachen and got several national and international appreciation of his work. From 2001 to 2006 he worked as postdoc in the research group of Prof. Dr. Doris Klee coordinating different projects in the biomaterials field. He established a state of the art cell culture facility at DWI – Leibniz Institute for Interactive Materials to analyse cyto-, hemo- and immunocompatibility of biomaterials. 2006 he joined the research group of Prof. Dr. Jürgen Groll to investigate cellular behavior at the cell-biomaterial interface. Additionally, he worked on the development of bioactivated, biodegradable scaffolds to enhance biocompatibility for tissue engineering and regeneration purposes. From 2006 to 2007 he prepared his practical year at the University Medical Centre RWTH Aachen University. In 2008 he achieved the license to practice medicine. 2008 he started working as resident in the clinic of surgery at the Berufsgenossenschaftliche Kliniken Bergmannsheil GmbH, Hospital of the Ruhr-University Bochum (RUB). In July 2014 he changed to the University Medical Centre Knappschaftskrankenhaus Bochum GmbH (RUB) as clinician scientist and operating orthopedic surgeon. He founded the clinical research group “Medical Biomaterials” at the Centre for Clinical Research (ZKF) at the RUB. Dr. Salber’s research is focused on the bio-evaluation of novel biomaterials. Furthermore, he is interested in the development and efficacy analysis of strategies to prevent implant-associated and periprosthetic microbial infections. In vivo simulation of complex device-tissue interactions using biomechanical reaction (BMR) systems and in silico tools to minimize in vivo experimental errors is another hot topic his group is working on. He is strongly interested in bone and vascular tissue engineering topics to develop in vitro biocompatibility assays based on human tissue equivalents.
Johann Wojta, PhD, is Head of the Organisational Unit Core Facilities and Head of Research at the Division of Cardiology at the Department of Internal Medicine II at the Medical University of Vienna. He is also Head of the Ludwig Boltzmann Cluster for Cardiovascular Research. He has published 316 papers in peer reviewed journals according to https://www.ncbi.nlm.nih.gov/pubmed/?term=wojta+j and a Hirsh-index of 57 according to https://scholar.google.at/citations?hl=de&user=CnvsdmYAAAAJ. Johann Wojta is Associate Editor of Cardiovascular Research, Section Editor of Thrombosis and Haemostasis and on the Editorial Board of Vascular Research. He is also Secretary of the Council on Basic Cardiovascular Science of the European Society of Cardiology. His group focusses on various aspects of the pathogenesis of atherosclerosis thereby integrating basic and clinical research. In particular, human primary cell types involved in this disease process, such as endothelial cells, smooth muscle cells, cardiac myocytes and fibroblasts, monocytes and macrophages, and preadipocytes and adipocytes and various mouse models are used as in vitro and in vivo models, respectively, to study processes involved in the development and progression of atherosclerosis, such as inflammatory activation induced by particular cytokines, matrix degradation and remodeling by proteases and angiogenesis and neovascularization.
Johannes Grillari’s research at Department of Biotechnology, BOKU – University of Natural Resources and Life Sciences Vienna, focus is on improving our understanding of the molecular and physiological changes that occur during cellular aging, their impact on organismal aging and age associated diseases, specifically in skin and bone. In addition, he is interested in engineering of mammalian cells to establish relevant and standardisable cell model systems and cell factories as well as cells for regenerative medicine. Johannes Grillari has graduated in Biotechnology at the University of Natural Resources and Life Sciences Vienna (BOKU) in Austria, where he also accomplished his PhD in the field of cell aging in 1999. Since then he has founded and is leading the Christian Doppler Laboratory on Biotechnology of Skin Aging at the Department of Biotechnology at BOKU. He has worked as visiting scientist in the lab of Angus Lamond in Dundee, Scotland, for half a year in the field of RNA biology. In 2010 he was appointed Associate Professor, in 2011 he co-founded Evercyte, a company generating and providing immortalized cells for in vitro toxicology, biopharmaceutical and cosmetical research and development, where he also acts as CSO. In 2013, he co-founded TAmiRNA, a company interested in identifying circulating miRNAs as biomarkers for aging and age-associated diseases. He has published more than 135 peer reviewed articles, holds 13 patents and has been invited speaker to more than 150 international conferences and departmental seminars. He has received several awards including the Walter-Doberauer award for aging research.
Jonathan Knowles, PhD, is Professor of Biomaterials Science at the Eastman Dental Institute, University College London. He is also the UK lead for the EU funded Discoveries Centre for Regenerative and Precision Medicine and also has a visiting position in the Department of Nanobiomedical Science & BK21 PLUS NBM Global Research Center for Regenerative Medicine. More recently a new joint UCL Eastman-Korea Dental Medicine Innovation Centre has been established. He is Editor in Chief of the Journal of Biomaterials Applications and also Editor in Chief of the Journal of Tissue Engineering. He is also on the editorial board of a number of other journals, including Biomaterials. His research mainly centres around degradable materials for hard and soft tissue reconstruction and his research has resulted in over 300 publications and over 20,000 citations. He has during his career also been involved with a number of professional organisations, as both a member but also supporting the organisations by taking an active role on the committees. He is a Fellow of both the Royal Society of Chemistry and the Institute of Materials Minerals and Mining and has in the past served on the IoM3 London Materials Society committee. He was also elected as a Fellow of the Institute of Medical and Biological Engineers, in the USA.
Jöns Hilborn received his Ph.D. in polymer chemistry from the Royal Institute of Technology in Stockholm, which was followed by seven years in industry before he joined the Swiss Federal Institute of Technology in Switzerland for eight years. He is since 2001 the head of the Polymer Chemistry program at the Department of Materials Chemistry, Uppsala University in Sweden. He has extensive management experience from life science industry and international and national research project. His research interests are in the design, synthesis, and preparation of polymers and specific materials for tissue regeneration and delivery of bioactives. The current focus is on injectable in-vivo gel forming matrices that act on endogenous cells to regenerate tissue and the development of RNAi to allow translation to therapies. Chemistry, biology, engineering is combined with medicine to bring basic research findings from the lab bench to the clinic and commercial applications. He served as president of “Tissue Engineering and Regenerative Medicine International Society” (TERMIS), which he was a part of creating. He is a frequently invited speaker at international events and has published >200 scientific papers (h=53), 26 patent applications and has started 7 companies.
Jorge Luis Cholula-Díaz, PhD, got his doctorate in Inorganic Chemistry from the University of Leipzig, Germany, in 2013. In 2015, he became faculty member of the School of Engineering and Sciences at Tecnologico de Monterrey, Mexico, where he is a Research Professor. He is leader of an experimental group – the NanoStructured Materials Laboratory – working in the following research areas: synthesis, characterization and biomedical applications of noble metal (Au, Ag & Ag/Au) nanostructures; synthesis of nanocrystalline graphite thin films by aerosol assisted chemical vapor deposition (AA-CVD) for opto-electronic applications; and synthesis and characterization of transition metal oxides as thin films and nanostructures for electrochemical biosensing. Dr. Jorge L. Cholula Díaz is a member of the Mexican National System of Researchers since 2017.
Jos Olijve is Sr. Project Manager/Principle Scientist at the gelatin company Rousselot. At Rousselot he is responsible for the new product and application developments among others in biomedical applications. An important part of the development work is to determine the role of endotoxin in biomaterials on cellular activities. Besides endotoxin also processing of gelatin into structures like microspheres, nanospheres, coatings, nanofibers is an important part of the development work. Before joining Rousselot he worked at FujiFim Manufacturing Europe B.V. Where he was responsible for the development of photographic gelatins and for characterization and the development of medical recombinant gelatin products. Inventor of 15 patent and author/co-author of 8 scientific papers.
Jose Miguel Garcia-Martín, PhD, obtained his Ph.D. in Physics at Universidad Complutense de Madrid (Spain) in 1999. Then he moved to Université Paris-Sud (France) with an individual Marie Curie fellowship, where he spent almost three years. In 2003 he joined Instituto de Microelectrónica de Madrid (IMM) with a "Ramon y Cajal" contract, where in 2006 he became Tenured Researcher of the Spanish Research Council (CSIC). In 2017 IMM changed to Institute of Micro and Nanotechnology, where he is now Research Scientist and Head of the Department of Fabrication and Characterization of Nanostructures. During several months in 2017 he was a Fulbright Visiting Scholar at Northeastern University (Boston, USA). His research work focuses on the study of different nanostructures (such as nanoparticles, nanocolumns, lithographed elements and thin films) with applications in various fields: magnetism, plasmonics and biomedicine. In particular, in this latter field, he works in antibacterial coatings and in nanostructured electrodes for cell stimulation. He leads the projects entitled “Large area advanced materials based on nanopillars and nanoparticles” and “Nanoimplant”, which won the IDEA²Madrid Award (a partnership of the Madrid Government and the Massachusetts Institute of Technology, MIT). He has co-authored 77 articles and 2 patents. He has given 27 invited conferences and his h-Index is 29.
Judith Heikoop, PhD, is Managing Director of IME Medical Electrospinning. The main theme in her career is innovation for health. Both in Biotechnology/Pharma as well as in Medical Devices she has successfully transformed research ideas into marketed products. Currently, her focus is to develop Medical Electrospinning equipment and technology to overcome barriers for fiber-based scaffolds to enter the clinic and answer serious unmet medical needs. Fiber-based scaffolds represent a tremendous promise for regenerative medicine and are capable of mimicking the human extracellular matrix and facilitate the human body to regenerate itself. This will enable patients, suffering from an impaired quality of life due to congenital defects, trauma or aging, to benefit from the most innovative and sustainable medical solutions.
Jürgen Groll holds the chair for Functional Materials in Medicine and Dentistry at the University of Würzburg. His research interest comprises applied polymer chemistry for life sciences, biomimetic scaffolds, immunomodulation, nanobiotechnology, and biofabrication. He holds the ERC consolidator grant Design2Heal that concerns the evaluation of design criteria for immunomodulatory scaffolds. Since January 2018, he is spokesman of the collaborative research center “From the fundamentals of Biofabrication to functional tissue models” (http://trr225biofab.de/). Prof. Groll received his Ph.D. from the RWTH Aachen University in 2005. From 2005 to 2009, he worked in industry in the field of functional coatings and biocomposite materials. In parallel, he built up a research group on polymeric biomaterials at the DWI Interactive Materials Research Institute in Aachen. He is board member of the International Society for Biofabrication and editorial board member of the journal Biofabrication. His work has been recognized by several awards such as the Bayer Early Excellence in Science Award 2009, the Reimund-Stadler award of the Division of Macromolecular Chemistry of the German Chemical Society in 2010 and the Unilever Prize of the Polymer Networks Group in 2014.
Julia Kzhyshkowska, PhD, is a head of department for Innate Immunity and Tolerance and Prof. for Cell and Molecular Biology at the Institute of Transfusion Medicine and Immunology, Medical Faculty Mannheim, Ruprecht-Karls University of Heidelberg. As a visiting professor she also leads the laboratory of Translational Cellular and Molecular Biomedicine at Tomsk State University, Russia. She is an author and co-author of 77 original paper and 19 review articles, editor of Special Issues of Current Pharmaceutical Design and Immunobiology, Section Editor of Immunobiology, member of seven scientific communities. She has supervised 16 MD and PhD thesis. Her laboratory has worked more than 15 years on systems biology and functional analysis of macrophages in physiological and pathological conditions. Major achievements have been made in the understanding of the mechanisms of macrophages activation and plasticity, signal transduction and intracellular membrane transport. Current interdisciplinary projects are focused on the identification mechanisms of macrophage interaction with biomaterials. In her laboratory the unique modes has been established for the analysis of the beneficial and detrimental effects of biomaterials on human innate immune responses, and for the identification of the patient-specific profiles. She coordinated several international projects dealing with macrophages-based diagnostic and therapeutic approaches, and currently acts and a principal investigator on the international projects aimed to develop new implant materials that program immune system to suppress inflammation and to accelerate tissue regeneration.
Julian R Jones (Professor of Biomaterials at Imperial College London) is an expert on bioactive glasses and hybrids. He has >130 articles (h index 40, > 1000 cites pa, Web of Science) and 4 patent applications and has co-edited three biomaterials text books. He was elevated to Fellow of the Society for Glass Technology in 2018, Fellow of the American Ceramics Society in 2015 and was awarded an ISCM (International Society for Ceramics in Medicine) Excellence Award in 2016; the 2014 Vittorio Gottardi Award from the International Commission on Glass (ICG) and the Robert L. Coble Award (American Ceramics Society) in 2010. He has secured >£5M funding as PI (>£16M total) since 2009 (EPSRC, i4i, GSK, EU, Innovate UK) and is Chair of the Applications Cluster of Technical Committees of the International Commission on Glass (ICG) and Vice-chair of the Bioceramics Division of the American Ceramics Society.
Justin J Cooper-White currently holds the positions of Deputy Director and Senior Group Leader in the Australian Institute for Bioengineering and Nanotechnology (UQ), Professor of Bioengineering in the School of Chemical Engineering (UQ), Director of the Australian National Fabrication Facility - Queensland Node (ANFF-Q), Co-Director of the UQ Centre in Stem Cell Ageing and Regenerative Engineering (UQ-StemCARE), Professor and Group Leader (Adjunct) within the Australian Regenerative Medicine Institute (Monash University), Vice President (Health and Medical) of the Queensland Academy of Arts and Sciences (QAAS), President of the Asian Biomaterials Federation, Chief Scientific Officer of Scaled Biolabs Inc., a lab-on-a chip start-up based in San Francisco, and Inaugural Editor-in-Chief (since October 2016) of APL Bioengineering, published by American Institute of Physics Publishing (New York). Prof. Cooper-White has over 230 scientific publications, including >180 journal articles, 11 reviews, 6 book chapters, along with >150 conference abstracts. His work has been cited >9700 times. He has produced 6 Worldwide patents that have reached National Phase Entry in USA, Europe and Australia in the areas of formulation design for agriproducts, microbioreactor arrays (MBAs) and tissue engineering scaffolds. He has received numerous awards, including most recently CSIRO OCE Science Leader Fellowship (2013-2018), the AON Insurance and Life Sciences Queensland Regenerative Medicine Award (2015) and the NHMRC Marshall and Warren Award for Research Excellence (2015).
Kalliopi Alpantaki, is a Spinal and Orthopaedic surgeon, Athens Medical Center, Greece. She received her Medical Degree from the University of Crete, Greece and her doctoral degree in Medicine from the same university in 2008. Her PhD work focused on the determination of fine nerve structures of the tendon of the long head of the biceps and interpretation of the development of clinical symptoms. From 1997 to 2004 she received her training in Orthopaedics and Traumatology in the University Hospital of Crete. After her CCST (Orth) coalification, she continued her training in Orthopaedics and Spinal surgery in the St James’s University Hospital, Leeds, UK and in the James Cook University Hospital, Middleborough, UK respectively. From 2010 to 2013 she was a Consultant in Orthopaedics and from 2013 to 2017 a Lecturer in Orthopedics, in the University Hospital of Heraklion, Crete, Greece. She is currently a research associate at the Department of Materials Science and Technology, University of Crete. Her main clinical interest focusses on trauma and spinal surgery. Her research interests focus on the pathophysiology of intervertebral disc degeneration and on regenerative medicine (tissue engineering bone, cartilage, intervertebral disc).
Kara Spiller is an Associate Professor in Drexel University's School of Biomedical Engineering, Science, and Health Systems. Her research interests include the role of immune cells in tissue regeneration, the design of immunomodulatory biomaterials, and international engineering education. Her research is funded by the NIH, the NSF, and private foundations. Her awards include a Fulbright fellowship, the NSF CAREER award, and the United States nomination for the ASPIRE prize.
Katja Schenke-Layland currently holds a dual appointment as a Professor of Medical Technologies and Regenerative Medicine at the University Women’s Hospital at the Eberhard Karls University Tübingen (UKT), and the Director of the Natural and Medical Sciences Institute at the University of Tübingen (NMI). Katja is also an Adjunct Associate Professor in the Department of Cardiology at the University of California in Los Angeles, Co-Editor-in-Chief of Tissue Engineering, Part B and is an Executive Editor for Advanced Drug Delivery Reviews. Katja is the Study Dean for Medical Technology at the UKT and sits on the board of multiple journals and biomedical associations. Her work focuses on the translation of developmental processes into clinically relevant biomaterials and regenerative therapies and the development of diagnostic tools to discover and validate therapeutic candidates and diagnose disease.
Kelly Velonia has received the B.Sc. in Chemistry at the University of Crete. She holds a doctoral degree in Mechanistic Organic Chemistry from the University of Crete. In 2000 she joined the group of Prof. R.J.M. Nolte at the Department of Organic Chemistry of the University of Nijmegen (RUN), The Netherlands, as a post-doctoral fellow. In 2001 she joined the group of Prof. F.C. De Schryver at the Department of Chemistry, University of Leuven (KUL), Belgium, as a post-doctoral fellow and in 2002 returned at the group of Prof. R.J.M. Nolte as a Marie Curie Individual Fellow. In 2004 she joined the Department of Organic Chemistry of the University of Geneva, Switzerland, as an Assistant Professor. In 2007 she was appointed Assistant Professor at the Department of Materials Science, University of Crete (tenure 2010). Current research areas and interests include the synthesis and characterization of multifunctional peptide/protein-polymer hybrids, directed biomaterial assembly, structure-function relationships, biotechnological and material applications of synthetic biomaterials (e.g. drug delivery systems, nanoreactors), cascade (bio)catalysis, single enzyme catalysis and synthesis of bioplastics.
Ken Suzuki, MD PhD FESC is a clinical academic in the field of cardiac surgery, initially trained at Osaka University, Japan. Following completion of 10-year clinical training with a PhD award for his work on gene therapy for myocardial ischaemia-reperfusion injury, he was recruited to the Harefield Heart Science Centre, Imperial College London, UK (head; Prof Sir Magdi Yacoub) in 1998. In this Centre of excellence, he completed a series of research projects on stem cell therapy and gene therapy for treating heart disease. Subsequently Suzuki took up the chair of a new research department (Translational Cardiovascular Therapeutics) within the William Harvey Research Institute in 2007. Here, he continues basic, translational, pre-clinical and clinical cardiovascular research with a well-balanced, multi-disciplinary group. His major research interest is cell therapy for heart failure using mesenchymal stromal cells, bone marrow-derived mononuclear cells, and pluripotent stem cells. He particularly aims to develop the most effective cell-delivery route through investigating intramyocardial injection, antegrade/retrograde intracoronary injection and “epicardial placement” by using various types of biomaterials/tissue engineering. His research activity also includes investigations of myocardial innate immunity, i.e. toll like receptors (TLRs) and reparative (M2-like; alternative activated) macrophages, in relation to heart failure. Suzuki is a former Japan Society for the Promotion of Science PhD/post-doc Research Fellow and UK Medical Research Council Senior Clinical Fellow.
Kenneth Dalgarno (male) is Sir James Woodeson Professor of Manufacturing Engineering at Newcastle University, and is Deputy Director of the Arthritis Research UK Tissue Engineering Centre. For the past decade he has been researching in the area of additive manufacture for biomedical applications, with an increasing focus on bioprinting and biofabrication, with work supported by the EC, and in the UK by the EPSRC, Arthritis Research UK, the NC3Rs, Innovate UK and industry. His current research portfolio covers biofabrication for regenerative medicine and 3D tissue assays, with application to the musculoskeletal system, skin, and diabetes.
Kevin E. Healy, Ph.D. is the Jan Fandrianto and Selfia Halim Distinguished Professor in Engineering at the University of California at Berkeley in the Departments of Bioengineering, and Materials Science and Engineering. He served as Chair of the Department of Bioengineering from 2011 to 2015. He received a B.Sc. in Chemical Engineering from the University of Rochester in 1983. He obtained graduate degrees in Bioengineering from the University of Pennsylvania (M.Eng.: 1985; Ph.D.: 1990). He is a thought leader and innovator working at the interface between stem cells and materials science to develop dynamic engineered systems to explore both fundamental biological phenomena and new applications in translational medicine. His group currently conducts research in the areas of: bioinspired stem cell microenvironments to control stem cell lineage specification and self-organization into microtissues or organs; bioinspired systems for regenerative medicine; biological interfaces; and, microphysiological systems for drug toxicity screening. Major discoveries from his laboratory have centered on the control of cell fate and tissue formation in contract with materials that are tunable in both their biological content and mechanical properties. These materials find applications in medicine, dentistry, and biotechnology. He is an elected Fellow of the American Institute of Medical and Biological Engineering (AIMBE), American Association for the Advancement of Science (AAAS), Biomaterials Science and Engineering (FBSE), Biomedical Engineering Society (BMES), and recently received an Alexander von Humboldt Foundation Award. He has chaired the Gordon Research Conference on Biomaterials and Biocompatibility, and has been honored with the 2011 Clemson award for outstanding contributions to basic biomaterials science. He is a named inventor on numerous issued United States and international patents relating to biomaterials, therapeutics, stem cells, and medical devices, and has founded several companies to develop these systems for applications in biotechnology and regenerative medicine.
Kieran Ryan, PhD, has a Bachelor Degree in Biochemistry and a Doctoral Degree in Microbiology from the National University of Ireland, Galway. He has worked in research laboratories in Ireland, the USA and the UK. His interests lie at the interface of industry and academic research and since 2015 he has been the Commercialisation Executive with responsibility for life sciences at the Technology Transfer Office at NUI Galway. He is a Registered Technology Transfer Professional.
Laura Suter-Dick is currently Professor for Molecular Toxicology in the School of Life Sciences at the University of Applied Sciences Northwestern Switzerland (FHNW). She is a European Registered Toxicologist (ERT) and holds a PhD in biology. During her career, she acquired more than 15 years of research experience in Pharmaceutical Industry before moving to academia in 2012. During her career at industry, she specialized in mechanistic toxicology, with a strong focus on advanced in vitro systems, alternative to animal methods, and toxicogenomics. She is actively involved in teaching and supervises bachelor, master and PhD students. She is president of Swiss biotechnet and member of the Swiss national initiatives SCAHT and 3RCC. She is part of the scientific panel of ESTIV (European Society of in vitro Toxicology) and Swisstox.
Laurent Muller got his PhD in Biochemistry and Cell Biology in 1996 in Université Paris-Orsay, France and received further training at the Louisiana State University Medical Center in New Orleans, USA. He was appointed as an INSERM researcher at the Collège de France in Paris in 2001. His work is focusing on the vascularization of tissues constructs. He has first been studying angiogenesis and the associated extracellular matrix remodeling in the context of development and ischemic cardiovascular diseases. In the course of these studies, he has developed 3D culture models of capillary formation in hydrogels and investigated the role of cross-linking enzymes of the lysyl oxidase family. These 3D culture models have then been used in his group in order to characterize the angiogenic potential of endothelial progenitor cells and of mesenchymal stem cells. He is now further developing these models in the context of tissue engineering, with a special focus on the generation of *in vitro* pre-vascularized tissue constructs. Another aspect of his work includes the development of biomimetic approaches based on cross-linking enzymes for the improvement of the angiogenic properties of hydrogels of natural polymers, including tropoelastin and collagen. He is a member of the boards of the French Society for Angiogenesis (SFA) and of the imaging facility of the CIRB. He has co-authored 41 papers that have been cited over 1,500 times (H-index 23).
Leanne Mullen, PhD, is Senior Publisher, Polymers, Elsevier. Leanne completed a PhD in Materials Science from the University of Cambridge. She has been working in publishing since 2012. During her publishing career, she has worked in various disciplines including applied mathematics, materials science, physics and engineering. Leanne is currently Publisher of *Progress in Polymer Science, Materials Today Bio, Materials Today Chemistry, Polymer, European Polymer Journal, Polymer Degradation and Stability, Reactive and Functional Polymers, Progress in Organic Coatings* and *Polymer Testing*. Leanne’s role also involves managing both the International Conference on Multifunctional, Hybrid and Nanomaterials and the International Symposium Frontiers in Polymer Science.*
Lei Dong received his Bachelor in Biotechnology (2003) and Ph.D. in Biochemistry and Molecular Biology (2007) from Nanjing University. Lei then undertook his postdoctoral training at School of Chemistry & Chemical Engineering, Nanjing University before he joined the faculty of School of Life Sciences, Nanjing University at 2010. Lei now is a professor of Pharmaceutics and Biology at and a principal investigator at Nanjing University. As Principal Investigator, Lei has published articles as (co-)corresponding author in ACS Nano, Cancer Research, Advanced Functional Materials, Advanced Science, Biomaterials, Trends in Biotechnology and Advanced Drug Delivery Reviews, among other recognized journals. His current research focuses on developing new strategies for tissue regeneration and organ synthesis based on artificial tumor microenvironments and the principles of synthetic biology.
Lia Rimondini, graduated in Dentistry at Università di Bologna, Italy, and lecturer at Universities of Bologna, Milano, and Insubria. Since 2005 she is Professor at Università del Piemonte Orientale. She has strong and documented experience in development and pre-clinical characterization (in-vitro and in vivo studies, microbiological studies) of implantable- and nano-biomaterials mainly addressed for muscular-skeletal and dental tissues regeneration or substitution. She is the Past-President of the Italian Society for Biomaterials.
Liam M Grover is a biomaterials scientist whose research focuses on designing materials that enhance the tissue regeneration process. He studied for both his undergraduate degree (biomedical materials science) and his PhD on the development of a novel bioresponsive ceramic (under the supervision of Jake Barralet) at the University of Birmingham, UK. On completion of his PhD, Prof. Grover spent two years working at McGill University, Montreal, where he was awarded a CIHR Skeletal Health Scholarship to study the role of a range of proteins and condensed phosphates in the formation of minerals. He returned to the University of Birmingham in 2006 to establish a research group in the School of Chemical Engineering. In the time since, Prof. Grover has held funding from a multitude of funding bodies, including: the EPSRC, BBSRC, MRC, NC3Rs, the Wellcome Trust, Orthopaedics Research UK, the MoD, the EU, the Drummond Foundation and the NIHR, as well as numerous industrial partners. Since 2006, he has been involved in raising more than £20m of research funding that has provided the University of Birmingham with an exceptional infrastructure for the development of medical technologies and directs the Healthcare Technology Institute located within the Institute for Translational Medicine. He has published more than 150 peer reviewed publications that describe the fundamentals of mineralisation, the development of novel materials and structures to regenerate both hard and soft tissues, and the structuring of soft materials. He has been an inventor on ten patent applications and has taken three medical technologies to the point of clinical trial. He was made a Fellow of the Institute of Materials at 30 and was made one of the youngest full Professors in the history of the University of Birmingham at 32.
Liesbet Geris is Collen-Francqui Research professor in Biomechanics and Computational Tissue Engineering at the University of Liège and KU Leuven in Belgium. Her research focusses on the development of in silico and in vitro models of skeletal tissue engineering processes. The in silico models range from machine learning and bioinformatics models to mechanistic multi-scale and multi-physics models. Liesbet is scientific coordinator of Prometheus, the Leuven R&D platform for skeletal Tissue Engineering (+/-60 researchers and clinicians). She has been awarded an ERC starting grant and an ERC consolidator grant to finance her research and has received a number of young investigator and research awards. She is a strong advocate for in silico (regenerative) medicine and is the current executive director of the Virtual Physiological Human Institute. She is member of the Tissue Engineering and Regenerative Medicine Society strategic alliance committee and one of the co-chairs of the 2021 TERMIS world conference that will be hosted in Maastricht (the Netherlands).
Lihi Adler-Abramovich is a Principal Investigator and head of the Laboratory of Bioinspired Materials at Tel Aviv University (TAU). The Laboratory is affiliated to the Goldschleger School of Dental Medicine, Sackler Faculty of Medicine at Tel Aviv University and the University Center for Nanoscience and Nanotechnology. Lihi studied biology at Tel Aviv University where she received both her M.Sc. (summa cum laude) and her Ph.D. (2010). Lihi received several prizes including the Colton Foundation Scholarship and the Marian Gertner Institute for Medical Nanosystems Scholarship. Lihi is the author of over 60 publications including *Nature Nanotechnology*, *Nature Chemical Biology*, *Nature Communications*, *Nano Letters*, *Science Advances* and *ACS Nano*. Work in the laboratory is focused on mimicking self-assembly processes that occur in nature, including biomineralization processes and the organization of short peptides and amino acids into ordered nanostructures. The Laboratory utilizes the resulting assembled architectures for various applications, such as 3D hydrogels for tissue engineering, which exhibit extraordinary mechanical properties and durability, along with biocompatibility and controlled drug release. The formation of hybrid hydrogels, formed by two or more different building blocks, results in a 3D hydrogel with novel and diverse properties that can be easily fine-tuned. In addition, the laboratory is also interested in the antimicrobial activity of nanostructures for coatings and incorporation into composite materials. https://lihi13.wixsite.com/lihi
Linda Gijzen, MsC, got her master’s degree in Toxicology and Pathobiology from the Radboud University, the Netherlands, in 2016. Since then she is working as a scientist at the Model Development department at Mimetas, the organ-on-a-chip company, in Leiden. There she is predominantly involved in the development of a kidney-on-a-chip model by using the microfluidic platform, the OrganoPlate®. The goal is to establish a predictive, cost-effective and high-throughput model that better recapitulate the \textit{in vivo} situation to serve as a tool to assess nephrotoxicity, develop new medicines, reduce the use of animal models and studying kidney diseases in a personalized fashion.
Lorenzo Moroni studied Biomedical Engineering at Polytechnic University of Milan, Italy, and Nanoscale Sciences at Chalmers Technical University, Sweden. He received his Ph.D. cum laude in 2006 at University of Twente on 3D scaffolds for osteochondral regeneration, for which he was awarded the European doctorate award in Biomaterials and Tissue Engineering from the European Society of Biomaterials (ESB). In 2007, he worked at Johns Hopkins University as a post-doctoral fellow in the Elisseeff lab, focusing on hydrogels and stem cells. In 2008, he was appointed the R&D director of the Musculoskeletal Tissue Bank of Rizzoli Orthopedic Institute, where he investigated the use of stem cells from alternative sources for cell banking, and the development of novel bioactive scaffolds for skeletal regeneration. From 2009 till 2014, he joined again University of Twente, where he got tenured in the Tissue Regeneration department. Since 2014 he works at Maastricht University, where he is a founding member of the MERLN Institute for Technology-Inspired Regenerative Medicine. In 2016, he became full professor in biofabrication for regenerative medicine. His research group interests aim at developing biofabrication technologies to generate libraries of 3D scaffolds able to control cell fate, with applications spanning from skeletal to vascular, neural, and organ regeneration. In 2014, he received the prestigious Jean Leray award for outstanding young principal investigators from the ESB and the ERC starting grant. In 2016, he also received the prestigious Young Scientist Award for outstanding principal investigators from TERMIS. In 2017, he was elected as faculty of the Young Academy of Europe.
Louis Penning (1963), PhD, is an associate professor in veterinary regenerative medicine at the Faculty of Veterinary Medicine, Utrecht University (UU) the Netherlands. He is an expertise member of the Dutch Society for Cell Biology and member of several other scientific societies, section editor and editor of two scientific journals and is member of the UU-iGEM guidance team. He has done a PhD and post-docs in molecular oncology, molecular endocrinology and molecular cardiology. This broad experience and open mind pays off now at the Faculty of Veterinary Medicine where he is responsible for the molecular and cell biology research in internal medicine and (neuro)surgery with a focus on stem cell biology. Hobbies include outdoors (sailing) and classical martial arts.
Luigi Ambrosio, Director of the Institute of Polymer, Composites & Biomaterials, National Research Council, Naples, Italy. He received the doctoral degree in Chemical Engineering (1982) from University of Naples "Federico II'. Director of Chemical Sciences & Materials Technology Department, CNR (2011-2017). Fellow of American Institute for Medical and Biological Engineering (2001) and Fellow of Biomaterials Science and Engineering (2004). President of the European Society of Biomaterials (2007-2013). Member of the High-Level Group on Key Enabling Technologies, European Commission (2010-2015). Member of the International Advisor Board of Sichuan University and Co-Director of MPBRC, SCU-CNR Joint Research Centre. He is recipient of the ESB "G. Winter Award", for the high worldwide contribution to the Biomaterials Science and of the 2017 China-Italy Science and Technology Innovation Cooperation Award. Research interests include design and characterisation of polymers and composites for medical applications and tissue engineering, rheology of biological fluids, structural properties of natural tissue, properties and processing of polymers and composites and nanostructures, hydrogels and biodegradable polymers, additive technologies. Publications include over 300 papers on international scientific journals and book, 18 patents, over 140 invited lectures and over 500 presentations at international and national conferences.
Lynn Csontos is the Senior Director of Quality Assurance and Regulatory Affairs at STEMCELL Technologies. She has worked in the biotech industry for over 23 years transitioning from Chemical Development into Quality Assurance and Regulatory Affairs approximately half way through her career. Although her background is primarily with small molecule API and drug products, she has been able to leverage her knowledge of the regulations surrounding small molecules, peptides and lipids to navigate the regulatory landscape that is currently being defined for cellular and tissue engineered therapies. Working at STEMCELL Technologies since 2008 she has had the opportunity to witness first-hand the ever changing compliance requirements as they relate to regenerative medicine and is excited to be a part of an organization that is helping shape the future landscape of this emerging field.
Maïté Rielland is currently leading the Biomaterial and Bioprinting team in L’Oréal Advanced Research. Bachelor in Biology, she specialized during her Master in development and stem cells. Obtained her PhD at the French National Institute of Agronomical Research where she studied the defects which arise after nuclear transfer in mouse cloned embryos, focusing in the establishment of culture protocols for in vitro cell models. Afterwards, during her postdoc, she spent 1 year at Mount Sinai Medical Center then 3 years at the New-York University (NYU) Medical Center investigating 2D and 3D in vitro models. In 2014, she joined Advanced Research L’Oréal tissue Models team to establish new skin tissue models and install the Bioprinting platform.
Manuel Salmeron-Sanchez is Head of Biomedical Engineering at the University of Glasgow. He did a PhD in Valencia and postdoctoral work at the Institute for Macromolecular Chemistry in Prague and the Katholieke Universiteit Leuven. In 2005 he was appointed as Assistant Professor at Universitat Politècnica de València, promoted to Associate Professor in 2008 and Full Professor in 2010. He did a sabbatical year at the Georgia Institute of Technology and moved to the University of Glasgow in 2013 as the Chair of Biomedical Engineering. Manuel holds a Consolidator grant from the European Research Council (ERC) to investigate growth factor delivery systems. This work has attracted significant additional funding from the ERC (PoC, 2 awards) and the Medical Research Council (MRC) in the UK and has set up the basis for a programme of research to help civilians affected by landmines, funded by Find a Better Way – a charity founded by Sir Bobby Charlton. Overall, his work spans fundamental mechanisms at the cell/material interface as well as translational research that has saved from amputation the leg of a first veterinary patient, a dog called Eva (https://goo.gl/1Z3r8t). He has authored more than 150 papers in major journals including PNAS, Science Advances, Nature Biomedical Engineering and Advanced Materials. He has had his research featured in newspapers, websites and TV channels around the world.
Manuela T. Raimondi; My background is in Mechanical Engineering and I received my PhD in Bioengineering in 2000. My career developed at Politecnico di Milano, where I am currently a Full Professor of Bioengineering at the Department of Chemistry, Materials and Chemical Engineering "G. Natta". I teach the course "Technologies for regenerative medicine" at the MS program in Biomedical Engineering. I am the Principal Investigator of four active projects in industrial bioengineering: three ERC-funded projects (one Consolidator and two Proof-of-Concept) and a project funded by the Italian Ministry of University and Research. In 2003-2008 I have activated and directed a Biomechanics lab inside the hospital IRCCS Galeazzi Orthopaedic Institute in Milano. I trained and supervised three bioengineers that applied integrated computational/experimental methods to study the biomechanics of orthopaedic devices, primarily hip and knee prostheses, spinal fixators, trauma fixators, maxillo-facial implants and engineered cartilage replacements. In 2009 I established the group of Mechanobiology at Politecnico di Milano. I have activated and I direct two labs (the “Mechanobiology lab” and the “Live Cell Imaging lab”) in which I based my team. We develop frontier tools for bioengineering research, such as nanoengineered stem cell niches and miniaturised windows for intravital imaging. Our long-term goal is to develop the potential of stem cells as tools in regenerative medicine, cell modelling and drug discovery.
Manus Biggs is a lecturer at NUI Galway and leads a research group within The Centre for Research in Medical Devices (CURAM). His highly interdisciplinary research is focused on the brain-machine interface, the development of electrically active biomaterial nanotechnologies in regenerative medicine and biodegradable biosensors. To date, Dr Biggs has published 48 peer-reviewed publications (31 as the senior author) and 10 conference proceedings and 7 book chapters. He has published original research papers in Nature Biomedical Engineering (IF TBA), Advanced materials (IF 21.95), Advanced Functional Materials (IF 13.325) and Small (9.58). He has secured 3.2M in competitive research funding and from industry collaborators to date. In recognition of Dr Biggs research to date, he has been awarded the 2014 UK Society for Biomaterials Larry Hench Outstanding Young Investigator award and in 2016 the NUI Galway Presidents Award for Research Excellence. Dr Biggs has organised symposia at the European Materials Research Society meeting, in Poland 2014, The World Biomaterials Congress in Montreal 2016, The European Society for Biomaterials Meeting, Maastricht 2018. Manus has given over 20 invited podium talks and has edited special issues on emerging scientific topics published in Advanced Functional Materials (IF 13.325), Nanomedicine: Nanotechnology, Biology and Medicine (IF 6.692) and Nanomedicine (Lond) (IF 5.824).
Marc Thurner is a visionary, entrepreneur and pioneer in 3D bioprinting technologies. His company regenHU Ltd, is recognized as an industry leader in the development of innovative biomedical solutions. A micro technology engineer Graduate, Marc started his professional career as an R&D engineer, managing international projects for the high precision automation industry. His avant-gardiste view that the future of regenerative medicine lay in converging engineering and biomedical science, brought him to found regenHU Ltd in 2007. In 2012 Marc created the regenHU spin-off Vivos Dental Ltd, specialized in innovative 3D-printed bone grafting solutions for oral bone augmentation. A pioneer in 3D bioprinting technologies, regenHU develops leading-edge solutions in biotechnology and tissue engineering that enable scientific and clinical breakthroughs. The Swiss-based company collaborates with a global network of scientific innovators and industry players and leads the development of biomedical products for regenerative medicine and drug discovery. Marc Thurner and the regenHU team are passionate about addressing the current and next generation biotechnology challenges to help the progress of Life Sciences.
Marco Thio is Business Development Manager of The Electrospinning Company, an SME that designs and manufactures biomaterial medical devices for use in tissue engineering, regenerative medicine and drug discovery. He graduated in 2002 at the Radboud University in Nijmegen, the Netherlands with a degree in Biology, followed by an academic career in tumour immunology and a PhD in inflammatory disease. Since 2011, his focus lies on the development, launch and sales of biomaterials in the orthopaedic & dental sector. In 2017 he joined The Electrospinning Company.
Marcy Zenobi-Wong is an Associate Professor of Tissue Engineering and Biofabrication at ETH Zürich, Switzerland. She obtained her PhD from Stanford University in 1990 where she studied how mechanical forces influence skeletal development. After a post-doctoral fellowship in the Orthopaedic Research Laboratories, University of Michigan, she moved to the M.E. Müller Institute for Biomechanics in Bern, Switzerland, where she became Group Leader of Cartilage Biomechanics and completed her Habilitation in 2000. In 2003, she joined the Institute for Biomedical Engineering at ETH Zürich. The Zenobi-Wong research group is focused on the development of advanced biomaterials for cartilage regeneration using biofabrication technologies including bioprinting, two-photopolymerization and electrospinning. Dr. Zenobi-Wong is the author of 75 peer-reviewed publications and coinventor on 4 licensed patents. She is the co-initiator of the graduate level courses “Practical Methods in Biofabrication”, “Mechanobiology”, “Biological Methods for Engineers”, and “Practical Methods in Tissue Engineering” at ETH Zürich. She is currently Vice President of the Swiss Society for Biomaterials and Regenerative Medicine, and general secretary for the International Society of Biofabrication.
Maria Grazia Raucci is Research Scientist at Institute of Polymers, Composite and Biomaterials - National Research Council since November 2011. M.Sc degree in Biology Science and PhD in Chemical Engineering of Materials and Production – Biomaterials. Appointed Professor of Chemistry at Seconda Università degli Studi di Napoli (2001-2003). Scientific Responsible of Tissue Engineering & Cell Culture Laboratory of IPCB UOS Napoli/Portici (2014-today). Qualified Associate Professor in Materials Science and Technology, D.D. 1532/2016 - 09/D1 - art. 16, comma 1, Legge 240/10 (2017-today). She is involved in several national and international projects, among these she is scientific coordinator for the Project SECOND. R.I. - Secondment for the development of Research Innovation in Biomaterial Rapid Prototyping, H2020-MSCA-RISE-2016 (Marie Skłodowska-Curie Research and Innovation Staff Exchange). Her expertise includes in vitro biocompatibility analysis, cell-material interactions, design and development of injectable and scaffold ceramics and hybrid materials prepared by sol-gel method for tissue engineering, bioactivation of materials by using organic and/or inorganic bioactive signals and in vitro release of bioactive molecules and to evaluate their effect on cellular behavior using cell lines and human mesenchymal stem cells.
Maria Lagarkova, during her PhD, worked on problems of chromatin structure and DNA spatial organization. Then she continued her post-doctoral training in immunology studying TNF-lymphotoxins functions in mouse knockout models and at the same time her group was involved in the international project for search of new cancer antigens. During the last decade she worked in the field of developmental biology and stem cells. The group has established a number of hESC and iPSC lines and performed their detailed genetic and epigenetic analysis. They were the first who reported the epigenetic differences between human ESCs. The group has successfully established a collection of human iPSC lines including iPSC lines established from patients with neurodegenerative disorders.
Maria Vamvakaki is a Professor at the Materials Science and Technology Department, Univ. of Crete and an affiliated researcher at the Foundation for Research and Technology – Hellas (FO.R.T.H.) - Institute of Electronic Structure and Laser (I.E.S.L.). She is the leader of the Materials Synthesis Group and an expert in the synthesis and characterization of polymeric and organic/inorganic hybrid materials, “smart” stimuli-responsive materials, biologically active (co)polymers, supramolecular assemblies, micellar structures, polyelectrolytes/polyampholytes, microgels/hydrogels and surface modification methods. Prof. Vamvakaki holds a doctoral degree in Polymer Chemistry from the University of Sussex, U.K. From 1997 to 1998 she was a post-doctoral associate at the School of Chemistry, Physics and Environmental Science at the University of Sussex, and in 1999 she became a Visiting Assistant Professor in Chemistry at the Department of Physical Sciences of the University of Cyprus. From 2001 to 2004 she was a visiting Professor at the Department of Materials Science and Technology, of the University of Crete and a visiting scientist at the School of Chemistry, Physics and Environmental Science at the University of Sussex. In 2004, she was appointed Assistant Professor at the University of Crete, where she got promoted to Associate Professor in 2011 and Full Professor in 2018. She has extensive experience on “living” and controlled polymerization techniques to prepare polymers in solution or on surfaces and on stimuli-responsive polymer self-assemblies for use in biomedical applications. Since 2017 Prof. Vamvakaki is a senior editor of the journal *Materials Science and Engineering C: Materials for Biological Applications*.

Marianna Tryfonidou, Professor Regenerative Orthopedics, DVM, PhD, dipl ECVS (female). Professor Tryfonidou (1973) joined the department of Clinical Sciences of Companion of the Faculty of Veterinary Medicine (1998), followed an annual Internship and finished thereafter her PhD (2002) Cum Laude. In 2007 she certified as a veterinary surgeon (European College of Veterinary Surgeons (ECVS)), in 2015 was appointed as Associate Professor and as off February 2018 appointed as Professor Regenerative Orthopedics. The focus of her research is on understanding the underlying pathophysiology, unravelling cellular communications and on developing treatment strategies for musculoskeletal diseases, including back pain and osteoarthritis. Challenges are addressed by combining their multidisciplinary clinical background, involving unique spontaneous diseased canine models, with cutting edge biomolecular techniques. Results of in vitro and in vivo studies are interpreted with a clinical directive; experiments are designed with the translation from bench to bed in mind. Relevant expertise to the keynote: The group of Tryfonidou has set up and validated a unique preclinical platform for IVD degeneration. This platform has been employed extensively and with success for the validation of biomaterials that enable controlled release of anti-inflammatory medication and growth factors (IDiDAS, BMM). This research is continued in the ArIADNE consortium, granted by the Life Sciences Health initiative focusing on translation of these treatment strategies for osteoarthritis and chronic back pain. Prof. Tryfonidou has successfully co-supervised 10 PhDs and currently supervises 7 PhD students, 1 post-doc and two technicians. 72 papers have been published by Prof. Tryfonidou in peer reviewed journals (21 of which as a senior author within the past 6 years; H index 14 Web of Science). She has participated in large public-private partnerships (e.g. BMM IDiDAS, LSH ArIADNE, AO Spine SRN) where she coordinated translation of therapeutic strategies as work package leader, being successful at the cross road of industry, academia, clinicians and patients. She recently successfully initiated as coordinator a Horizon 2020 consortium (iPSpine) bring a transdisciplinary team of 20 partners together bringing advanced therapies for chronic back pain closer to the clinic.
Marie-Elizabeth A. Barabas, Managing Editor of Nature Partner Journals, completed her PhD under the direction of Cheryl Stucky at the Medical College of Wisconsin, where she studied peripheral receptors in postoperative and inflammatory pain. During her postdoctoral work in the lab of Michael Dyer at St. Jude Children’s Research Hospital, she optimized a protocol to reprogram adult murine retinal cells to induced pluripotent stem cells and then re-differentiate them into retinal tissue in a 3D culture system. Marie’s research diversity and passion for science communication played an integral part of her career transition to her current role overseeing a portfolio of Springer Nature research journals, which includes npj Regenerative Medicine and npj Genomic Medicine.
Marina Rubert was graduated in Biology and in Biochemistry by the University of Balearic Islands (Spain) in 2006. After graduating, she came to the Department of Biomaterials at the University of Oslo (UiO, Oslo) to work in collaboration with the spin-off company Numat AS. Her initial research training focused upon the characterization and identification of the active components used for promoting bone regeneration adjacent to titanium implants. In 2009 she started her PhD at the University of the Balearic Islands (UIB, Spain) and got a technician position at Numat Biomedical SL. Her work was focused on studying the role of potential therapeutic biomolecules in bone regeneration and on the development of new biomaterials to restore function in compromised skeletal structures. In 2013 she completed her PhD entitled “Development of biomimetic artificial peptides to facilitate bone repair” and she joined at ELECTROMED group at the iNANO center in Aarhus (Denmark). During her postdoc research she was primarily working on the identification and development of novel and biocompatible electrospun biomimetic nanofibers as drug delivery systems for their use in regenerative medicine. Since January 2014, she has joined at the Laboratory for Bone Biomechanics at the Institute for Biomechanics at ETH Zurich. Her main research interest is to provide human-based in vitro models for better understanding of the interplay between the factors and processes involved in bone tissue development in response to mechanical and biological stimulus. Her research is focused on the establishment of 3D bioprinted human-based bone organoids to advance on the identification, characterization and development of new bioactive components for their use in bone diseases.
Mario Gimona received his PhD in Genetics and Cell Biology from the University of Salzburg in 1990 and spent his postdoctoral period at the Cold Spring Harbor Laboratory in New York. He led research labs on actin cytoskeleton regulation and cell migration in Austria and Italy and was awarded a Marie Curie Excellence Grant by the European Union in 2004. He organized more than 10 research conferences, co-founded 2 scientific societies (the Protein Modules Consortium and the Invadosome Consortium) and co-authored over 70 publication. He was Scientific Coordinator for the “Scientific Competence“ track and Academic Advisor for medical students at the Paracelsus Private Medical University (PMU) in Salzburg. His current activities at the GMP Unit of PMU and with Celericon Therapeutics focus on the development of novel cell-based therapeutics. At the PMU he helped design and build a GMP-grade clean room laboratory where he heads the cell manufacturing unit and leads a team of researchers investigating the potential of multipotent stromal cell-derived extracellular vesicles in regenerative medicine for application in acute spinal cord injury, bone and tendon repair, and implantation-induced injury in the cochlea.
Martijn van Griensven (1974) studied in Leiden (NL) and was trained in Hannover (D). He was appointed as full professor for experimental trauma surgery in 2000. In 2005, he became co-director of the Ludwig Boltzmann Institute for Experimental and Clinical Traumatology in Vienna (A). In September 2011, he was appointed as director for the department of Experimental Trauma Surgery at the Technical University of Munich (D). His research areas are related to engineering methods for the musculoskeletal system using stem cells of different sources, biomaterials, gene therapy and mechanical loading. His most recent grants deal with engineering the enthesis (ligament-to-bone transition), oxygen measurement in scaffolds and also with miRNA usage for diagnostics and therapeutics. He has published 275 peer reviewed original papers, 2 patents, 24 book chapters and he has edited 4 books. His h-factor is 52 (Google Scholar). He has received several awards for his work, among others the young scientist award from the World Biomaterials Society. He serves currently on the council of TERMIS-EU as well as of the German surgical research society.
Martin Leahy is the Chair of Applied Physics at NUI Galway, Distinguished Visiting Professor at ICFO Barcelona and a serial entrepreneur having been technical and/or managerial lead of several successful spin-out companies in biophotonics and energy. Since his return to academia he has provided leadership as founding Director of the National Biophotonics and Imaging Platform, founding its education board and founding and chairing the International Biophotonics and Imaging Graduate Summer School (BIGSS). He has presided over several large research projects involving several groups. His main research interest is in the advancement of existing technologies such as laser Doppler and laser speckle as well as the development of new modalities such as TiVi and cmOCT for 2D, 3D and 4D imaging of the microcirculation. His group has invented the heart rate app which is now in use by more than 200 million people as well as cmOCT to image the microcirculation, nanosensitive OCT to sense nanostructure and multiple reference OCT to achieve a 100-fold reduction in size and cost. More recently, his group have developed a label-free superresolution microscope. He has secured more than €14M in external R&D funding since 2007 and his citation rate is rapidly rising since his return to academia. He is the coordinator of STARSTEM and partner in two other H2020 projects. Since 2010 he has delivered 50 international invited lectures and published more than 50 senior author journal articles and more than 500 patents cite his work. Professor Leahy retains a healthy involvement in industrial R&D, collaborating with start-ups like Compact Imaging and iThera and multinationals like Covidien and Fujifilm.
Martin Stoddart, FRSB has been working as a Principal Scientist at the AO Research Institute (ARI), where he is responsible for the Stem Cell Focus Area. His interests include the use of mesenchymal stem cells for bone and cartilage repair, in particular the role of mechanoregulation during the initiation of MSC chondrogenesis. This has led to an increased understanding of chondrogenesis under complex physiological loads in the absence of exogenous growth factors. He completed his bachelors in Biology in 1995 and MPhil in 1996 at the University of Aberystwyth. He completed his doctoral thesis in Oncology (University of Nottingham). In 2002 he took a sabbatical at the Centre for Molecular Orthopeadics, Harvard Medical School, Brigham and Womens Hospital, Boston, to learn viral gene transfer techniques. Dr. Stoddart was awarded an Honorary Professorship from the Albert-Ludwigs University, Freiburg, Germany in 2015 and an Honorary Professorship from the Institute for Science & Technology in Medicine, Keele University, UK in 2016. In 2016 he was elected Fellow of the Royal Society of Biology. He is Chair of the ORS Basic Science Education Committee and deputy co-chair or the ICRS Basic Science Committee. He is an Editor for Tissue Engineering Journal Parts A, B, C, Scientific Editor for eCM Journal and the Chair of the yearly eCM Conference. He has published over 90 papers, 10 book chapters and edited 2 books.
Mary Murphy, PhD, DSc is a principle investigator at the Regenerative Medicine Institute (REMEDi) at the National University of Ireland Galway, Ireland. Research interests focus primarily on the development of innovative medicines using mesenchymal stem/stromal cells (MSCs), MSCs derived from induced pluripotent stem cells and gene therapy to provide new modalities in patient care for osteoarthritis, bone repair and vascular calcification. Basic research is focused on the concept that stem cell depletion, or loss/alteration of function, contributes to the development of chronic degenerative diseases such as osteoarthritis and atherosclerosis, the use of the chondrogenic differentiation pathway of bone marrow-derived MSC as a model to study early changes in osteoarthritis development and the role of inflammation and epigenetics in disease progression. Current clinical research focuses on the therapeutic potential of MSCs and she is involved with the ADIPOA2 Phase 2 clinical trial to assess adipose-derived stromal cells in osteoarthritis. Tissue engineering concepts are targeted to cover various elements including assessment of novel materials for cartilage repair and the development of targeting strategies for non-invasive delivery of therapeutic cells and anti-inflammatory or pro-chondrogenic agents to osteoarthritic joints using nanoparticles. Applied research has a focus on the manufacturing of MSCs for therapeutic use and address novel fully defined serum/medium for cell growth and scale-up for robotic, economic manufacture.
Matej Buzgo, MSc has experience in development of drug delivery systems by electrospinning, centrifugal spinning and electrospraying. His main interest is in preparation of core/shell nanofibers by needleless electrospinning and centrifugal spinning for drug delivery of proteins and small molecules. He is coauthor of >25 scientific publications, >5 national and European patents and leads one European and one nation grant projects.
Matteo Moretti is the head of the Regenerative Medicine Technologies Laboratory at Ente Ospedaliero Cantonale (EOC), Lugano, Switzerland and of the Cellular and Tissue Engineering Laboratory at the IRCCS Galeazzi Orthopedic Institute, Milan, Italy. He previously worked as a post-doc fellow at the Massachusetts Institute of Technology, Harvard-MIT Division of Health Science and Technology, Langer Lab. He obtained a European Doctorate in 2005 at Polytechnic of Milan, partially spent as student at the Tissue Engineering Laboratory with Prof. I. Martin, University of Basel. All of his titles, including BEng (Polytechnic of Milan) and M.Sc (Trinity College Dublin, with Prof. PJ Prendergast) are in Bioengineering. His main research interests are within advanced cell culture technologies for musculoskeletal and cardiovascular tissues. In particular, he focused on engineering tissue complexity and in vitro models, 3D tumor models, tissue microvascular networks and multi-scale bioreactor systems as key tools for viable and accessible cellularized therapeutic and diagnostic systems. Industrially, he has licensed one of his patents, has worked as coordinator of financed projects for Fidia Advanced Biopolymers (FAB, Abano Terme, Italy) and has been co-founder of 2 biotech start-ups (SKE s.r.l., Italy and Cellec A.G., Switzerland) focused on bioreactor technologies. His scientific awards include a N.A.S.A. Tech Brief Award for the development of scientific or technical innovations. He has been member of TERMIS since its foundation, co-founder of the SYIS section and then TERMIS-EU treasurer since 2015. He has authored more than 65 publications in peer-review impacted scientific journals.
Matteo Santin is Professor of Tissue Regeneration at the School of Pharmacy and Biomolecular Sciences, University of Brighton, UK, Academic Lead for the Healthy Futures, the University framework for the research and enterprise in the field of health, and the Director of the Brighton Centre for Regenerative Medicine and Devices. His career in biomedical research and teaching started in 1989 and it has been marked by significant achievements that were internationally recognised in 2005 by the European Society for Biomaterials who conferred him the Jean Leary Award. From 2008 to 2015 Prof. Santin was Associate Editor and later Editor-in-Chief of the Journal of Materials Science: Materials in Medicine, the official journal of the European Society for Biomaterials of which is currently Emeritus Editor. Prof Santin has been the President of the European Society for Biomaterials from September 2013 to September 2017 and vice-chair of the ETP on Nanomedicine, Regenerative Medicine Working Group. He is a member of various scientific advisory groups in the UK and across Europe. He is the founder and director of 2 start-up companies with a mission in biomaterials for biomedical applications and pre-clinical handling of cells, Brighton Wound Care Ltd and Tissue Click Ltd. His scientific interests include natural biomaterials, synthetic biomimetic nanostructured biomaterials able to control tissue regeneration, and in vitro clinically-reflective models for the testing of biomaterials and tissue engineering constructs. He has published over 70 papers, filed 9 patents applications and unveiled for the first time the biochemical and cellular mechanisms of inflammatory response to silk fibroin, new cellular mechanisms leading to the failure of cardiovascular stents and the tissue regeneration potential of novel soybean-based biomaterials and biomimetic dendrons.
Matthew Baker is an assistant professor with the MERLN Institute for Technology-Inspired Regenerative Medicine at Maastricht University in the Netherlands. An organic chemist by training, he and his co-workers are dedicated to making better biomaterials bond-by-bond, aimed at mimicking the complexity found in the natural extracellular space. Never satisfied with what they can buy, their lab specializes in polymer synthesis, supramolecular materials, dynamic hydrogels, and materials for 3D printing. The work from his lab is pioneering the ability to study the effect of material timescales on cell behavior in well-defined 3D environments.
Maurice N. Collins is a lecturer at the School of Engineering in medical grade Polymers and Principal Investigator at the Bernal Institute and the Health Research Institute at University of Limerick in Ireland. Currently, he is the Lead Principal investigator and coordinator of the H2020 funded LIBRE consortium (lignin for carbon fiber), the largest consortium in biobased carbon fibre research in Europe as well as being Co-PI on multiple national funded projects. He is also a member of the Bernal Institute leadership team. His research interests include polymers development for applications in tissue scaffolds and biobased carbon fibre precursor materials for composites as well as the development of 3D printable Polymers. Dr Collins has a strong track record in attracting industrially funded research projects including Mitsubishi Materials, Henkel, J&J, Nokia-Bell labs, etc. His industrial work has led to 2 licencing agreements and 6 patent applications. Coupled to this, he has authored >100 publications on Polymer Science related topics and his research has featured in various national and international media outlets. His research has been recognised through various awards including: Marie Curie Actions Award, Licencing Agreement Award, Best Journal Paper Award, Highlight Conference Paper Award, ISI highly cited award and UL Seed Funding. He is a reviewer for > 30 international Journals including Soft Matter, Growth Factors, J of Tissue Eng. & Regenerative Medicine, International J of Biological Macromolecules, Langmuir, RSC Nanoscale, and Carbohydrate Polymers. He sits on the editorial board of Carbohydrate Polymers and is guest editor for the International Journal of Biological Macromolecules. He is proposal assessor for the Polish Academy of Science, Israeli Ministry of Science and H2020. Maurice lectures polymer therapeutics to postgraduate students and Tissue Engineering to Undergraduates. He currently supervises 9 PhD candidates, 2 postdocs and is Course Director for the MSc in Biomedical Device Materials.
Mauro Alini graduated in Chemistry from the University of Lausanne (Switzerland) in 1983. Since then he has been involved in connective tissue research, starting from his Ph.D. research work, which focused on the isolation and characterization of proteoglycans extracted from both normal human mammary gland and carcinomas thereof. In September 1988, he joined the Joint Diseases Laboratory (under Dr. A. R. Poole’s direction) at the Shriners Hospital in Montreal to work on quantitative and qualitative changes in extracellular matrix proteins (particularly proteoglycans and collagens) of the growth plate tissue before and at the time of cartilage matrix calcification during endochondral bone formation. In January 1995, he was appointed as an Assistant Professor at the Division of Orthopaedic Surgery of the McGill University (Chair Prof. M. Aebi) and head of the Biochemistry Unit of the Orthopaedic Research Laboratory, working to develop new biological approaches to treating intervertebral disc damage. Since July 2000, he is in charge of the Musculoskeletal Regeneration Program (40 scientists) at the AO Research Institute (Davos, Switzerland), focusing on cartilage, bone and intervertebral disc tissue engineering. Since September 2009 is also Vice-Director of the same Research Institute. He received the Marshall R. Urist Award in 2015 from the Orthopaedic Research Society (USA).
May Griffith, PhD, is a Professor at the Department of Ophthalmology at the University of Montreal, Canada and a researcher at the Maisonneuve-Rosemont Hospital Research Centre. She holds the Caroline Durand Foundation Chair in Cellular Therapy of the Eye and is Director of the Cornea and Anterior Segment Axis of the Quebec Vision Health Research Network. MG is best known for her pioneering work in translational regenerative medicine, for the development of biosynthetic corneal implants that promoted regeneration of the human cornea in a first-in-human clinical trial. MG continues her bench-to-bedside work in cornea regeneration and more recently demonstrated stable regeneration of the corneas of patients with severe pathologies diagnosed as being at high-risk for rejecting conventional donor cornea transplantation. She also continues to develop new biomaterials for use in ophthalmology and in particular, short peptides as functional equivalents to extracellular matrix macromolecules.
Michael Detamore, PhD, is the Founding Director, Professor, and Stephenson Chair of the Stephenson School of Biomedical Engineering at the University of Oklahoma. He earned his Bachelor Degree in chemical engineering from the University of Colorado and his Ph.D. in bioengineering from Rice University. He spent 12 years at the University of Kansas as a P in the Department of Chemical & Petroleum Engineering before moving to the University of Oklahoma. He is the recipient of the NSF CAREER Award and the Coulter Foundation Translational Research Award, and was a Fulbright Scholar and Visiting Professor at NUI Galway in Ireland in 2011. He is also a Fellow of the American Institute of Medical and Biological Engineering and the Biomedical Engineering Society, and a recipient of the Iwao Yasuda Award from the Biomedical Engineering Society. His primary research interest is regenerative medicine, including biomaterials and stem cells. Regenerative medicine efforts include nerve regeneration, but focus primarily on bone and cartilage regeneration, including the temporomandibular joint (TMJ), knee, cranium, and trachea, with a particular focus on translational regenerative medicine. Central research themes include umbilical cord stem cells and gradients in tissue engineering. He has published over 120 papers, and has been awarded six U.S. patents. In addition to his research, he enjoys teaching and has won numerous teaching awards.
Michael Gasik, is Professor at Aalto University Foundation, School of Chemical Engineering, Finland; previously visiting professor and fellow in University of Manchester (UK), Tohoku University, School of Engineering (Japan), A. Avogadro University of Eastern Piedmont, School of Medicine (Italy). Member of European Connected Health Alliance, European Orthopaedic Research Society, Japan Society for Promotion of Science, Aalto Health Technology Platform, TechNet Alliance (honorary). Representative of Finland in COST networks NAMABIO, NEWGEN, SPRINT for biomaterials and regenerative medicine. Over 250 different publications and patents. Main recent activities in biomaterials design and evaluation for restorative and regenerative applications, prevention of infection and management of immune response of the host towards biomaterials and scaffolds. Development of alternative in vitro methods (‘3R’) and methods for medical devices translation (2017/745). Biomaterials and medical devices applications for orthopaedic, dental and tissue engineering areas.
Michael Monaghan is Assistant Professor in Biomedical Engineering in Trinity College Dublin Ireland leading a multidisciplinary research group in the School of Engineering and is a Principal Investigator within the Trinity Centre for Bioengineering (TCBE http://www.tcd.ie/bioengineering/). The aim of the Monaghan Lab is to develop in vitro biomaterial/bioreactor platforms that recapitulate the physiological characteristics of both diseased and healthy heart tissue towards organoid culture systems, the advanced manufacturing of multifunctional therapeutic biomaterials, and advanced imaging techniques towards disease diagnosis and microenvironment metabolism. Lab Webpage: www.monaghanlab.com. He has published several seminal papers (LINK) and to date has generated over €700,000 in research funding. Accolades include the Julia Polak European Doctorate Award (2015), Marie Sklodowska-Curie Individual Fellowship (2013), and travel awards to support research exchanges in Germany (European Molecular Biology Organisation 2010, Deutscher Akademischer Austausch Dienst 2011). He is an invited reviewer for several journals in the field of tissue engineering, regenerative medicine and advanced biomaterials. Michael is also treasurer of the Matrix Biology Ireland Society (MBI) and the Chair of the 2017 MBI Meeting in Dublin, Ireland. He has served as chair-elect of the student and young investigator section (SYIS) of the TERMIS EU Chapter, chair of this section (2016-2017) and a full TERMIS EU council member since 2018.
Michael Raghunath, MD, is Professor for Biochemistry, Protein Technology & Tissue Engineering at the Zurich University of Applied Sciences in Wädenswil, Switzerland. He heads the Center for Cell Biology & Tissue Engineering and is Director of the Competence Center for Tissue Engineering for Drug Development (TEDD). He received his PhD (habilitation) in Physiological Chemistry and Pathobiochemistry from the University of Münster, Germany. After clinical training in dermatology, he worked in industry as director R&D. From 2003-2016 he was an Associate Professor in the National University of Singapore. His basic and translational research experience spans more than 30 yrs during which he became an internationally distinguished scientist in the field of matrix and skin biology (wound repair, cornification disorders). Developing macromolecular crowding as principle in cell biology, he has created a novel field in Tissue Engineering to build cell-specific and lineage-directing microenvironments. He was an ETS Walton Visiting Fellowship at National University of Ireland, Galway and a Raine Visiting Professors at the University of Western Australia. Editorial Boards: Journal of Tissue Engineering and Regenerative Medicine, International Journal for Bioprinting, Current Opinion in Biomedical Engineering. He is council member of the TERMIS-EU chapter, is in the executive committee of the Swiss 3R Competence Center, Biotechnet, and chairs the board of TEDD.
Miguel Castilho is an Assistant Professor of Biofabrication at the Department of Orthopedics, University Medical Center Utrecht (UMCU) and a Guest Researcher at the Department of Biomedical Engineering, Eindhoven University of Technology (TU/e). His research focuses on manufacturing bio-inspired structural materials for musculoskeletal tissue engineering, in particular bone. A special focus lies on developing novel additive fabrication methods to control the local anisotropic mechanical properties of biofabricated implants. At the UMCU, he personally leads the research efforts on the development of custom additive manufacturing systems for biomaterials processing and biofabrication. Dr. Castilho holds a MSc degree in Mechanical Engineering and a PhD in Biomedical engineering (with high distinction) from the Technical University of Lisbon (IST, Portugal). In addition, he was a visiting research scholar at the Department for Functional Materials in Medicine and Dentistry, University of Würzburg, Germany, and worked in a biomaterials company for the CE marking of 3D printed bone substitutes. For his contributions to the Biofabrication field he was awarded the Young investigator award from the Wake Forest Institute for Regenerative Medicine, USA.
J Miguel Oliveira BSc, PhD (Portuguese, M, 40 years old) is a Principal Investigator “Investigador FCT 2012 and Investigador FCT 2015” at the PT Government Associate Laboratory ICVS/3B’s (http://www.3bs.uminho.pt/users/miguelyoliveira). He is the Director of Pre-Clinical Research at the FIFA MEDICAL CENTER, Estádio do Dragão, Porto, PT since Fev. 2013 and Pro-Director of the 3B's Research Group, Univ. Minho, PT. Currently, he is a Lecturer in Doctoral Program in Tissue Engineering, Regenerative Medicine and Stem Cells (TERM&SC) at UMinho, PT (since Dec. 2013). He is also an Invited lecturer at the Faculty of Medicine, U. Porto (since Sept. 2013) and Dept. of Polymer Eng., UM, PT (2009-present). Along the years he has focused his work on the field of biomaterials for tissue engineering, nanomedicine, stem cells and cell/drug delivery. More recently, he set-up a new research line within the ICVS/3B’s on 3D in vitro models for cancer research. As result of his proficiency, he has published so far more than 260 scientific contributions in scientific journals with referee, being 4 of those review papers produced under invitation. Miguel Oliveira was approved 16 patents, published 5 books, 2 special issues in scientific journals, and more than 70 book chapters in books with international circulation. He has participated in more than 250 communications in national/international conferences and has been invited/keynote speaker in more than 40 plenary sessions. He has an h-index of 34, i10 of 82 and received more than 4935 citations. He has been awarded several prizes including the prestigious Jean Leray Award 2015 from European Society for Biomaterials for Young Scientists for Outstanding Contributions within the field of Biomaterials. He is very active on the elaboration and scientific coordination of several PT and international funded projects. In addition, he is member of the advisory /editorial board of the Journal Bio-Design and Manufacturing, Journal of Materials Science: Materials in Medicine, International Journal of Tissue Engineering, Journal ISRN Biomaterials, The Journal of Experimental Orthopaedics, Journal “Recent Patents on Corrosion Science”, and referee in more than 40 international journals.
Mikaël Martino obtained his PhD in Biotechnology and Bioengineering at the Ecole Polytechnique Fédérale de Lausanne (EPFL) Switzerland, in 2011. During his PhD thesis, he principally focused on how the extracellular matrix regulates the activity of growth factors. Notably, he developed novel growth factor delivery systems for regenerative medicine applications including angiogenesis, chronic wounds and bone regeneration. Then, Mikaël Martino received fellowships from the Swiss National Science foundation to do research in immunology at the Immunology Frontiers Research Centre, Osaka University, Japan. During postdoctoral training, he concentrated on how the immune system influences tissue repair and regeneration. Pursuing research at the interface between immunity and regenerative medicine, he became Assistant Professor at Osaka University in 2015. In mid 2016 Mikaël Martino became an Associate Professor and EMBL Australia Group Leader at the Australian Regenerative Medicine Institute in Monash University, Australia. His laboratory try to understand how we can reactivate regenerative pathways by controlling the immune system. His team takes an interdisciplinary approach using genetic mouse models and bioengineering methods such as protein engineering and biomaterial functionalization. His long-term goal is to work at the interface between bioengineering and immunology to design novel regenerative medicine strategies.
Nadja Weissenbacher graduated from Ludwig Maximilian University of Munich with a degree in Veterinary Medicine. Afterwards she worked as a small animal veterinarian in private practice and in a referral clinic. She then wrote her doctoral thesis also at Ludwig Maximilian University of Munich, before she joined the Paracelsus Medical University, Salzburg as a research associate in the musculoskeletal field. She is currently working at the Institute of Tendon and Bone Regeneration with special research interest in tendon and bone healing and regeneration. Besides her scientific work she is deputy head of the Central Animal Facility and Animal Welfare Officer at her university. She leads the Core Facility Animal Surgery and is besides that a convened member of the animal experiments committee of the Austrian Ministry of Education, Science and Research where she enthusiastically cares for laboratory animal welfare topics.
Naoki Kawazoe is currently a Senior Researcher at Tissue Regeneration Materials Group, Research Center for Functional Materials, National Institute for Materials Science (NIMS). He received his Ph.D from Department of Material Chemistry at Kyoto University in March 1999. Then, he became a teaching associate in Department of Biological Science and Technology, The University of Tokushima. In April, 2000, he moved to Nara Institute of Science and Technology (NAIST) as a teaching associate. He then worked as a postdoctoral researcher at National Institute of Advanced Industrial Science and Technology (AIST) and at Toray Industries collaborating with Osaka University. He moved to NIMS in April, 2006 and has been working at Dr. Guoping Chen’s group since then. His current area of interest is biomaterials with controlled release of bioactive molecules for tissue engineering and nano/micropatterned biomaterials for cell function manipulation. He received the SRB Excellence Award from Romanian Society for Biomaterials in 2018.
Narine Sarvazyan is a tenured professor at the George Washington University School of Medicine and Health Sciences (USA). Her research interests encompass a variety of cardiovascular topics including mechanisms of cardiac arrhythmias, tissue engineering approaches for heart and vessel repair and new imaging modalities for visualizing pathophysiological tissue states. She served as a principal investigator on multiple projects sponsored by the National Institutes of Health, the National Science Foundation, the American Heart Association and other agencies. She is also a Fulbright Scholar and a recipient of the American Heart Association Established Investigator Award.
Navid Khani is Head of R&D of BellaSeno GmbH, Biocity, Leipzig, Germany. He received his PhD in manufacturing engineering from Sabanci University, Istanbul, Turkey in 2017. His main theme of research for his doctoral studies was on modeling, analysis, and additive manufacturing of Heterogeneous multi-material structures. BellaSeno is a preclinical stage medical device company developing innovative porous bioresorbable breast implants. His focus at bellaseno is on modeling of implants and CAD/CAM integration considering additive manufacturing for production. He has published 17 scientific publication (Journal articles, patent and conference articles).
Nicanor I Moldovan is Associate Research Professor at Indiana University-Purdue University at Indianapolis (IUPUI), Indiana and the Director of 3D Bioprinting Core Laboratory at ‘Richard L. Roudebush’ Veterans Administration Medical Center in the same city. He received an MS in Biophysics at the University of Bucharest and his PhD in Cellular Biology from the ‘N. Simionescu” Institute of Cellular Biology and Pathology, also in Bucharest, Romania. After a post-doctoral training in cardiovascular medicine at Johns Hopkins University, he became Assistant Professor and performed pioneering bio-medical (in neovascularization) and bio-engineering (in scaffold-based tissue engineering) research at the Ohio State University in Columbus, OH. His current work at IUPUI is in the areas of spheroids-based tissue assembling (for which he secured the acquisition of a ‘Regenova’ bioprinter from Cyfuse, Japan, as the first at an academic institution in USA), bioink-assisted bioprinting (on a ‘3DDiscovery’ bioprinter from regenHU, Switzerland), hybrid biofabrication, implant bio-compatibility, and in computational modeling of cells and tissues. He is an Associate Editor of the Journal of Cellular and Molecular Medicine.
Nicholas D Evans is an associate professor in bioengineering at the University of Southampton. He has held personal fellowships at Stanford University and at Imperial College, which have led to his current focus on two main areas of research at the University of Southampton: nanotechnology and biomaterials in bone and skin repair. He has >1600 citations, with papers published in respected journals such as Nature Materials and Biophysical Journal. The major focuses of his current work include the development of acoustically-sensitive drug carriers for bone repair (in collaboration with Prof Eleanor Stride at the University of Oxford) and the use of nanoclay biomaterials for skin repair and regeneration (in collaboration with Dr Jonathan Dawson at the University of Southampton).
Nicolas L’Heureux holds a Bachelor’s degree in Biochemistry, a Master’s degree in Immunology and Microbiology, and a Ph.D. in Molecular and Cell Biology from the Laval University in Quebec City, Canada. He completed his training as a post-doctoral fellow of the American Heart Association at the Bioengineering Department at UCSD. In 2000, he co-founded Cytograft Tissue Engineering, Inc. (San Francisco) where he held the position of Chief Scientific Officer for 15 years. He joined the INSERM (French Institute of Health and Medical Research) in 2015 as a Research Director at the Laboratoire de Bioingénierie Tissulaire (U1026), or BioTis, at the University of Bordeaux. Dr. L’Heureux has raised over 20 MS in private funding and won seven NIH grants. He is the recipient of a chair from the Excellence Initiative of Université de Bordeaux (IdEx) as well as an ANR grant. He recently was awarded an ERC advanced grant. Dr. L’Heureux has been an early believer in the possibility of developing completely biological tissue engineering approaches to produce constructs with physiological biomechanical properties. At a time when synthetic scaffolds were seen as a defining part of any tissue engineered construct, he demonstrated that the cell-assembled extracellular matrix (CAM), produced by normal human cells in vitro, can be used to create completely biological, living, autologous and human tissues that display remarkable mechanical strength without the need for any exogenous scaffolding. During his years at Cytograft Tissue Engineering, Dr. L’Heureux has sought to accelerate the translation of this technology to the clinic. This effort has led to the first clinical use of tissue-engineered blood vessels under arterial pressure and demonstration on long-term durability. Recent clinical data have also shown the possibility of using allogeneic CAM. Current efforts focus on the development of textile-based approaches to assemble threads of CAM into blood vessels.
Nihal Engin Vrana is Vice President (Scientific Affairs) of Protip Medical (which developed World’s first artificial larynx) and an affiliated researcher in INSERM UMR 1121. He obtained his PhD in 2009 at Dublin City University as a Marie Curie ESR fellow. His major research interests are titanium implants, tissue engineering, cell encapsulation, immunomodulation, real-time monitoring of implants, biomaterial assessment and cell biomaterials interactions. He has been the scientific coordinator of 2 European Projects (EuroTransBio Bimot and FP7 IMMODYGEL) and he currently coordinates H2020 PANBioRA project (11 countries, 17 partners). He has published 63 articles in peer-reviewed academic journals (over 1700 citations, h index: 23), 8 book chapters and holds 4 European patents. He edited two books for Taylor and Francis on Cell Material Interactions (2015) and Immune response to Biomaterials (2018). His awards include Parlar Foundation Thesis of the Year (2006), ESB Translational Research award (2011) and 2nd Aegean R&D Patent competition 1st place award (2012). He is Associate Editor of Frontiers in Biotechnology and Bioengineering and Cells, Tissues and Organs.
Nuno M Neves is an Associate Professor at the Research Institute I3Bs on Biomaterials, Biodegradables and Biomimetics. This is a research unit of Excellence, directly funded by the Portuguese Foundation for Science and Technology (FCT). The I3Bs also integrates the PT Associate Laboratory ICVS/3B’s, as homologated by the Portuguese Ministry for Science and High Education, being Nuno M. Neves one of the members of the Board of Directors. He is the Director of the FCT Doctoral Program in Advanced Therapies for Health (PATH) and the Director of the Integrated Master Course of Biomedical Engineering of the University of Minho. He is also the Erasmus Academic coordinator for the Biomaterials, Rehabilitation and Biomechanics branch of the Integrated Master Course of Biomedical Engineering of the University of Minho. As of May 2018, he is the author of 167 publications listed in the Web of Science (115+ peer reviewed international papers), with h-factor of 36 and a total number of citations of over 4150 (h:38;4600 in Scopus). He is an elected member of the Board of Governors of the European Society for Artificial Organs and is currently the responsible for the Tissue Engineering Working Group of the ESAO. He is a member of the Council of the European Alliance for Medical and Biomedical Engineering and Sciences (EAMBES) in representation of the ESAO. He was previously a member of the Council of the European Chapter of the Tissue Engineering and Regenerative Medicine International Society, having served as member of the Nominating Committee of the European Chapter.
Olga Tsigkou is a Lecturer in Biomaterials (Assistant Professor) and Programme Director for the MSc in Biomaterials at the School of Materials, Faculty of Science and Engineering at the University of Manchester, UK. Her research focuses predominantly in the application of stem cells, 3D porous scaffolds and hydrogels on tissue regeneration applications. She has developed robust protocols for 3D cell culture models in static and shear stress (bioreactor) culture conditions. Her research interests include cell-substrate interactions, vascularization strategies, \textit{in vitro} tissue modeling and substrate directed differentiation of stem cells. She has published highly cited papers on these topics in leading international journals (e.g. PNAS, Biomaterials and Advanced Functional Materials). Her published work includes more than 30 original research papers in international peer-review journals with over 1200 citations focusing in the fields of bone tissue engineering, bioactive glasses, vascularization, as well as imaging and material characterization. She is the Managing Editor of the Journal of Materials Science: Materials in Medicine and she has been serving as regular Reviewer for several distinguished international scientific journals, including Nature Communications, Scientific Reports, Tissue Engineering, PLoS One etc. She has also been acting as a Reviewer for The Academy of Medical Sciences, U.S.-Israel Binational Science Foundation and Fondation Santé. She has presented her research in more than 50 international and national meetings and conferences.
Ori Bar-Nur, PhD, heads the Regenerative and Movement Biology laboratory in the Department of Health Sciences and Technology at ETH Zurich. He received his PhD degree with distinction in 2012 from the Hebrew University of Jerusalem for his research on human induced pluripotent stem cells, which he conducted in the lab of professor Nissim Benvenisty. Following his PhD studies, he completed postdoctoral training in the lab of professor Konrad Hochedlinger at Harvard University, where he investigated the role of transcription factors and small molecules during cellular transitions. Since 2018 he serves as an Assistant Professor and a member of the Institute of Human Movement Sciences and Sport (IBWS) in ETH Zurich. The primary long-term goal of his laboratory is developing stem cell-based therapeutic approaches to treat degenerative loss of muscle mass. To this end, his research group employs state-of-the-art mouse transgenic models, direct lineage reprogramming methods as well as stem cell lines cultured in vitro to dissect the molecular drivers that orchestrate skeletal muscle regeneration. Dr. Bar-Nur’s work has been published in prestigious journals including Nature Biotechnology, Nature Methods and Cell Stem Cell. His latest work, published during 2018 in the journal Stem Cell Reports, describes an innovative approach to reprogram mouse somatic cells into expandable myogenic progenitor cells.
Ornella Parolini obtained her Biology degree in 1988 from the University of Milan where she graduated summa cum laude. In 1994 she completed her doctorate in Cellular and Molecular Biotechnology in Biomedicine. In May 1991, Prof. Parolini began her research experience abroad, where she worked for renowned research institutes such as St. Jude’s Children’s Research Hospital in Memphis, Tennessee (USA, 1991-1994). She was a Visiting Scientist in the Department of Immunology at the University of Vienna from 1995 to 1998, after which she became Head of the Laboratory of Molecular Immunology (1998-2002). Her research abroad was focused on the regulation of genes important in the development and proper functioning of the immune system, and also on hematopoietic stem cells and their clinical application, and she significantly contributed to the field of primary immunodeficiencies, being author of numerous publications. After ten years abroad Prof. Parolini returned to Italy with the aim to lead a research center at the Fondazione Poliambulanza Hospital. Since then, she has been the Director of the E. Menni Research Center (CREM) in Brescia (Italy), where she has pioneered research on the applications of placental stem cells in regenerative medicine. Currently, CREM is internationally recognized for its research and contributions in this field. In 2004 Prof. Parolini began her academic appointments at multiple Italian universities and became a visiting lecturer at the University of Granada (Spain, 2009-present) and University of Chengdu (China, 2014 to present). Since September 1, 2016, she is Full Professor of Experimental Biology at the “A. Gemelli” Faculty of Medicine and surgery, Università Cattolica del Sacro Cuore in Rome. Since November 1, 2017, she is President of the Degree Course of Health Biotechnology at the “A. Gemelli” Faculty of Medicine and surgery, Università Cattolica del Sacro Cuore in Rome. Prof. Ornella Parolini is author of over 140 publications in peer-reviewed scientific journals. She is also amongst the Top Italian Scientists of the Via-Academy.org. She is author of 2 patents, 12 book chapters, and is Editor of a book entitled “Placenta the tree of life”. In the field of stem cells in regenerative medicine, Prof. Parolini has held over 110 invited lectures in international congresses and/or institutes, has been scientific leader and organizer of 20 international events focused on the applications of placental stem cells in regenerative medicine. She is also a member of numerous scientific societies, including the International Placenta Stem Cell Society (IPLASS), in which she is a founding member and twice-elected President (2009, 2014).
Øyvind Halaas, PhD, is a professor in medicine at the Department of Clinical and Molecular Medicine at The Norwegian University of Science and Technology, Trondheim, Norway. He has a background in biotechnology, stem cells and immunology, and has established a group within Microsystems for Biomedicine. He is involved in projects related to 3D matrices for connective tissue, microfluidics and microelectronics for neuronal networks, Lab-on-chip photonic protein biosensors and nanoscale drug delivery systems. The main focus is however to combine of microengineering and immune cell biology to recreate immune functions outside the body, in particular the processes of T cell priming of the lymph node. In the lymph node paracortex, fibroblasts form a scaffold on which dendritic cells adhere and present antigen to naïve T cells passing by. The goal is to enable in vitro immunization for cancers and infectious diseases.
Patrick Kugelmeier studied medicine and did his medical thesis in islet transplantation for the treatment of Diabetes. The joy of research led to an MD-PhD program for the early differentiation of stem cells. Cell culture technologies at that time didn't allow for good data reproducibility, because stem cells were cultured in 2D. Fueled by the clinical need of small, size-controlled cell clusters to improve islet transplantation and the insights from the sensitivity of stem cells, he began to develop what was later to become the Sphericalplate 5D. After the MD-PhD program, he did his clinical training in visceral and transplant surgery followed by trauma surgery. Besides the clinical work, the Sphericalplate 5D was further developed. Finally, it became clear that this technology opens a new dimension in cell transplantation and regenerative medicine and Dr. Kugelmeier decided to quit surgery to fully live this vision within a startup-company, the Kugelmeiers AG.
Paul Wieringa, PhD, is an Assistant Professor leading the Neural Engineering activities in the Complex Tissue Engineering Department of the MERLN Institute for Technology-Inspired Regenerative Medicine at Maastricht University. Trained as an Integrated Engineer at the University of British Columbia, Canada, he received funding from the Natural Science and Engineering Research Council (NSERC) of Canada to develop his research in the area of peripheral nerve interfaces and completed his co-Ph.D. in 2014 from the University of Twente and Scuola Superiore Sant’Anna, Italy (cum laude) on the biofabrication of scaffolds for regenerative neural interfaces. This was followed by a post-doctoral fellowship from 2014 to 2017 at the MERLN Institute on technological development of electrospinning, melt electrowriting (MEW), and hybrid scaffolds to create specifically designed cell micro-niches for neural and regenerative medicine applications. In 2017, he was awarded the VENI personal grant by the NWO and was promoted to Assistant Professor in 2018, with a research focus on developing 3D in vitro platforms to explore the role of pancreas innervation in Diabetes as well as other pathologies and tissues.
Paul E Bourgine studied Biotechnology at the Ecole Superieure de Biotechnologie de Strasbourg-France, from which he obtained his engineering diploma in 2010 after a stay at the Ragon Institute of Harvard, MIT and MGH (Boston, USA). He subsequently moved to Switzerland and received his PhD in Cell Biology from the University of Basel in 2013. After a post-doc at the Biosystem department of the ETH-Zürich, Paul was appointed Associate Professor at Lund University-Sweden in 2018, where he opened the Cell, Tissue and Organ engineering laboratory. Paul is part of the Wallenberg Centre for Molecular Medicine and the Stem Cell Centre in Lund. Paul’s research aims at studying Bone as an organ model, understanding from a fundamental perspective how its constitutive tissues (bone, cartilage, bone marrow, vasculature) form, interact and regenerate. By exploiting innovative in vitro/in vivo models of Bone formation, his lab ambitions at compiling knowledge that could help the design of regenerative therapies. In particular, Paul’s group uses death-inducible human cell lines as factory units to produce molecularly customized biological tissues for skeletal repair. Paul is willing to promote innovation and creativity as its best in order to solve persisting & challenging problems in the field. This should be done by placing young scientists and undergraduates in the front line, especially upon international community events.
Paul Dalton is a Professor at the University of Würzburg, Germany with over 20 years’ of interdisciplinary experience in biomedical materials, including polymer processing, surgery, nanotechnology and hydrogels. A graduate from Curtin University, Australia, he was part of a successful team in the 1990s taking an artificial cornea from concept to the clinic at the Lions Eye Institute in Perth. Paul post-docced with Molly Shoichet at the University of Toronto, Canada, on neural tissue engineering topics and then with Martin Möller at RWTH Aachen, Germany, applying nanotechnology to life science applications. As a researcher at the University of Southampton, he performed experimental spinal cord surgery on rodents, while initiating melt electrowriting (MEW) research as a “hobby” on the side. The impressive capability of this direct writing approach led him to split his time between the Queensland University of Technology, Australia, and Shanghai Jiao Tong University in China until 2014 when he joined the University of Würzburg as the first professor in biofabrication in Germany. MEW is now recognized as a distinct class of additive manufacturing for the manufacture of biomedical materials.
Paul Gatenholm is professor of Biopolymer Technology at Chalmers University of Technology, Founder of 3D Bioprinting Center, and Director of Graduate School at WWSC. He is also Adjunct Professor at Joint School of Biomedical Engineering and Sciences at Virginia Tech and Wake Forest University and Adjunct Professor of Biomaterials at Wake Forest Institute for Regenerative Medicine in Winston-Salem, North Carolina, USA. He has been professor of Bioprocessing and Biomaterials at the Virginia Tech, Department of Materials Science and Engineering between August 2007 and April 2009. Dr. Gatenholm is a material scientist with interest in the biomimetic design of materials. His research includes biological fabrication through the use of enzymes, cells, and the coordination of biological systems. Dr. Gatenholm is particularly interested in designing and preparing new biomaterials which can replace or regenerate tissue and organs. During past five years he has dedicated his time to development of 3D Bioprinting technology which he believes will revolutionize the field of Medicine. He has published more than 300 papers and edited several books and has more than 8000 citations. He is elected member of Swedish Royal Academy of Engineering Sciences.
Paul Slezak, MD, graduated in 2009 from the Medical University of Vienna, Austria. In 2010 he became a research scientist at the Ludwig Boltzmann Institute for Experimental and Clinical Traumatology in the field of tissue engineering and regenerative medicine. The major research interest is in biophysical therapies to improve tissue regeneration when wound healing is impeded. Dr. Slezak manages a wound healing research group and heads a research group investigating local hemostasis which develops next generation hemostats. A recent research focus has been on the characterization of extracorporeal shockwave therapy (ESWT) and their effects on regeneration. In a co-operation with major manufactures of therapeutic shockwave applicators, both physical and biologic properties of the acoustic shock waves are evaluated. Next to his research interests Dr. Slezak is the CEO of a Spin Off company which aims to bring experimental therapies and approaches to the clinical field.
Paul V Hatton  PhD FIMMM has worked in the field of Biomaterials Science for over 25 years, where his focus is on the application of materials technologies for musculoskeletal tissue repair and regeneration. He has published well over 100 key papers in biomaterials and tissue engineering, and has supervised 33 PhDs to successful completion. He has also led a number of UK and EC projects, including one of the earliest European tissue engineering projects (SCAFCART, 2000-2005), and more recently has initiated research into multi-functional materials for medical and dental applications. Related to this, he has developed a strong translational programme working with industrial partners throughout Europe. Professor Hatton was President of the UK Society for Biomaterials (UKSB) in 2005-6, and later served as an elected member of the TERMIS EU Council. He currently sits on the Biomedical Application Division of the UK Institute of Materials, Minerals & Mining (IoM3). He is also passionate about the development of early career researchers and PhD students, supporting the EXPERTISSUES Network of Excellence (now an EEIG led by Rui Reis) as the Education & Training lead, and he has spoken at a number of meetings including sessions of the SYIS. He is currently responsible for the University of Sheffield’s participation in the UK EPSRC Centre for Innovative Manufacturing in Medical Devices, and actively participates in a number of major scientific and translational projects.
Pedro Costa is a researcher, inventor, educator and entrepreneur. He is the founder, CEO and CTO of the company BIOFABICS (Portugal), which is specialized in the creation of 3D biotissue analogues. Before that, he was the coordinator of the world’s first MSc Programme in Biofabrication at Utrecht University, manager of the Utrecht Biofabrication Facility and postdoctoral researcher at the University Medical Center Utrecht (Netherlands). Dr. Costa can be described as a biologist by training and engineer/maker by heart, given his undergraduate studies in applied biology followed by a PhD in biomedical engineering where he specialized in the application/combination of highly automated tools such as additive manufacturing (3D bioprinting) and bioreactor technologies in the field of tissue engineering and regenerative medicine. Such strategy is also being employed in the development of a new generation of truly 3D microfluidic organ/tissue-on-a-chip (and ultimately body-on-a-chip) devices. Dr Costa has previously worked in both academic and industrial environments in places such as Portugal (University of Minho), Belgium (Materialise NV), Australia (Queensland University of Technology) and Germany (Technical University of Munich). Dr. Costa has also received several awards in recognition for his work, among them the “2014 Translational Award” (European Society for Biomaterials), the “2014 European Doctoral Award” (European Society for Biomaterials) and the “2016 Young Investigator Award” (2nd place) (International Society for Biofabrication).
Pedro Morouço, PhD, is Associate Professor and Principal Investigator of Biofabrication at the Centre for Rapid and Sustainable Product Development – Polytechnic Institute of Leiria. By developing novel equipment for biofabrication, his group aims to be at the forefront in tailoring scaffolds for tissue engineering and regenerative medicine. Its main focus is on developing novel hybrid manufacturing processes for tissue engineering, but also in optimizing biomaterials/bioinks for tissue regeneration and drug delivery constructs. Currently, he is participating in 7 funded projects, focusing his research activity, mostly, on products and processes engineering, aiming to bringing the gap between the lab and in vivo applications. Science Communication is also a topic in which Pedro is involved; Two awards in the National Science Communications Contests and representative of Portugal in an international event, and was the winner of The Publishing Method competition 2017 promoted by the American Journal Experts.
Peter Timashev graduated from the Moscow State University of Fine Chemical Technologies in 2002. In 2006, he gained his PhD degree at the Karpov Institute of Physical Chemistry, and in 2016 - DSc degree. In 2016, he became a Head of the Department for Advanced Biomaterials at the Institute for Regenerative Medicine (Sechenov University, Russia). Since 2018, he has been working as a Director. His research interests cover the development of novel biodegradable biocompatible materials and approaches to their structurization (inc. laser-based technologies), 3D bioprinting, and clinical translation of tissue engineering.
Petra Kluger is a full professor for tissue engineering and biofabrication at Reutlingen University in Germany since 2017. Before she was head of the department cell and tissue engineering at the Fraunhofer Institute for Interfacial Engineering and Biotechnology in Stuttgart since 2013 and had a shared time professorship at Reutlingen University. She studied technical biology at the University of Stuttgart and started the research on interdisciplinary topics in the field of tissue engineering within her doctorate. Her first activity in the biofabrication area started in 2008 and since then her group focused on the use of extrusion based bioprinting techniques to manufacture human tissues and their future use as tissue models e.g. for drug screening or as cell-based implants for reconstructive or regenerative medicine. Beside her scientific activities, she is very dedicated in lecturing in the areas of issue Engineering and Biofabrication.
Philip Procter background and professional profile: I have over 30 years’ experience in research, development, marketing and business development of Orthopaedic medical devices including both metallic and biomaterials products. For over 7 years I have worked self-employed consultant (ConsultPhilipProcter SARL, France) working primarily with commercial mentoring of SME’s in the medical device sector. Biomaterials innovation/commercialisation in Ireland: In 2012 I co-founded an Irish start-up company GPBio Ltd, whose business focus is the development and commercialisation of tissue adhesives. In 2014 I put together a syndicate of SME’s around biomaterials for augmenting bone fixation in combination with orthopaedic implants. Their commercial success led to the company CelgenTek Innovations (Shannon) being purchased by Zimmer Biomet in 2016. Translational research: I focus on translational research to projects that link University based research to relevant clinical problems. These include: development of injectable biomaterials, implant coatings to enhance implant fixation, & local delivery of antiporotic and antibiotic drugs. I direct applied research at Angstrom Laboratories University of Uppsala Sweden that focusing on adhesives (1) intended for use in human tissue repair.
Philippe Lavalle holds a PhD degree in Biophysics in 1998 from University of Strasbourg. He got the position of "Research Director" at INSERM in 2011. Since January 2013, he co-manages as deputy director the INSERM Unit called "Biomaterials and Bioengineering" (45 staff members). Ph. Lavalle focuses his research at the interfaces of different disciplines ranging from chemistry of materials and cell biology. More particularly, he designed new materials/coatings with like self-antimicrobial or mechano-responsive properties. To date, Ph. Lavalle has applied for six patents and published more than 100 peer review publications cited more than 5000 times and his h index is of 36. He has presented his work at numerous scientific meetings. His team is currently involved in 2 European Projects.
Piergiorgio Gentile is a Lecturer in Bioengineering in the School of Engineering at Newcastle University. He obtained his B.Sc., M.Sc. and Ph.D. in Biomedical Engineering from the Politecnico di Torino, Italy. In 2012, he moved to UK after being awarded with an IEF Marie Curie Fellowship. His research deals with the nano- and micro- scale design, manufacturing and surface functionalisation of biomimetic scaffolds for musculoskeletal regeneration. He is author of more than 45 peer-reviewed papers in the leading journals in biomaterials and tissue engineering field (including Advanced Healthcare Materials, Acta Biomaterialia, Biomacromolecules etc.), three book chapters and a research highlight in RCS Biomaterials Science. To date he has an $h$-index of 20 and his research has led to 2 patents. He has presented in many prestigious international conferences and symposia, including eight as an invited speaker. The recognition of his standing within the community has also led to invitations to chair or organise scientific sessions at several national (ie. BiTEG in Sheffield (2014)) and international conferences (ie. TERMIS 2016 in Uppsala-Sweden, TERMIS 2015 in Boston-US and SIB in Baveno-Italy), three invitations to contribute to special editions of scientific journals, in addition to a book chapter. His honours include the “A. Mazzoldi” award by the Italian Group of Bioengineering (GNB) for his PhD dissertation, the “Larry Hench” Young Investigator award by UK Society of Biomaterials (UKSB), and, recently, the Mobility Santander Award for a research collaboration with Politecnico di Torino, Italy.
Pierre Layrolle is INSERM Research Director, and head of the team ‘Inflammation and cell communications in bone pathologies’ at INSERM U1238, PHY-OS at the Faculty of Medicine, University of Nantes, France. He obtained a PhD *cum laude* related to calcium phosphate biomaterials at the Polytechnic National Institute of Toulouse in 1994. After a 2-years post-doctorate in Tsukuba, Japan, he joined the tissue engineering company IsoTis in The Netherlands where he was senior researcher. Over 5 years in this company, he developed a bioactive coating for orthopaedic implants and calcium phosphate bioceramic scaffolds. In 2003, he joined the INSERM in Nantes to conduct translational research on bone tissue engineering associating stem cells and biomaterials. In 2007, he was awarded the Jean Leray Award from the European Society for Biomaterials. He is the coordinator or partner of several European projects (Reborne, Orthounion, Paragen, Maxibone) that supported the completion of 6 clinical trials using stem cells in bone regeneration. In 2010, he has founded the spin off company Biomedical Tissues that produces an innovative synthetic resorbable dental membrane. He is the inventor of 15 patents, authored about 180 publications and regularly invited to present his research in international conferences.
Pierre Weiss, PhD, DDS, is Professor in Biomaterials at the Dental Surgery Department at the University of Nantes. He holds a Dental Doctorate, Master of Science in biomaterials and a PhD in Biomaterials from the University of Nantes. His scientific activities include skeletal tissue engineering, physicochemistry of hydrophilic polymers used to make hydrogels for synthetic extracellular matrix and bone substitutes. His research interests include the chemistry and characterization of macromolecular solutions and hydrogels to prepare synthetic extracellular matrices for tissue engineering of cartilages and bone. His scientific skills are on macromolecular chemistry and characterization including FTIR, Rheology, mechanical experimentation and material design of nano particles blended with viscous solution before injection and cross linking into a 3D scaffold with live cells. Pierre has managed clinical research in Odontology. He is the Scientific Director of the Pays de la Loire Regenerative Medicine Cluster Bioregate. He is also the president of the Society for Biohydrogels, Vice Dean of Nantes Dental School and is a member of the Scientific Council of Nantes University. He has authored more than 150 publications as well as 7 patents and has a h-index of 42 with over 4,000 citations.
**Prasad Shastri** is the Professor of Biofunctional Macromolecular Chemistry and the Director of the Institute for Macromolecular Chemistry at the University of Freiburg. He is also a core faculty of the DFG funded BIOSS excellence cluster where he holds the position of Professor of Cell Signalling Environments. He received his Ph.D. from Rensselaer Polytechnic Institute (USA) and carried out his post-doctoral work with Prof. Langer at MIT. He has published over 120 peer-reviewed papers and authored several proceedings, extended abstracts and over 50 issued and pending patents. His laboratory is active in the area of biomaterials, mechanobiology, intracellular delivery of nanomaterials, cancer biology, functional imaging and in vivo engineering of tissue and made several notable contributions in materials science and biology and pioneered the "in vivo bioreactor" paradigm for de novo engineering bone and cartilage tissue.
Ralph Mueller, PhD, is currently a Professor of Biomechanics at the Department of Health Sciences and Technology and heads the Laboratory for Bone Biomechanics at ETH Zurich in Switzerland. He studied electrical engineering at ETH Zurich, where he also received his doctoral degree. Subsequently, he was involved in the development of a compact desktop micro-tomographic imaging system that since has been commercialized and is now marketed worldwide. The research he has completed and is currently pursuing employs state-of-the-art biomechanical testing and simulation techniques as well as novel bioimaging and visualization strategies for musculoskeletal tissues. His approaches are now often used for precise phenotypic characterization in mammalian genetics, mechanobiology as well as tissue engineering and regenerative medicine. He is an author of over 500 peer-reviewed publications in international scientific journals and conference proceedings. His work has been cited over 30,000 times on Google Scholar with an h-index of 90. In 2015, he was elected to the Swiss Academy of Engineering Sciences (SATW) and as a Fellow of the European Alliance for Medical and Biological Engineering and Science (EAMBES). In 2017, the European Research Council (ERC) awarded him with a prestigious ERC Advanced Grant.
Raquel M Gonçalves is a researcher at the Microenvironments for New Therapies Group at i3S, Instituto de Investigação e Inovação em Saúde/INEB, Institute of Biomedical Engineering, in Porto, Portugal. She has a degree in Chemical Engineering, Biotechnology from the University of Lisbon in Portugal, and she was a visiting researcher at the University of Nevada, Reno, USA and at the Institute of Orthopedic Research and Biomechanics, Ulm, Germany. Her scientific interests have focus the development of stem cells- and biomaterials-based therapies to modulate the inflammatory response and promote tissue regeneration. Particularly she has coordinating international projects in the area of intervertebral disc regeneration. She is also invited professor at the University of Porto, lecturing in MSc and PhD programs and supervising MSc and PhD students. Also, she has a passion for public awareness of science, especially for children and adolescents.
Rena Bizios, Ph. D., a chemical/biomedical engineer by training, is the Lutcher Brown Chair Professor in the Department of Biomedical Engineering at the University of Texas at San Antonio, San Antonio, Texas, USA. During her career in academia, Professor Bizios has taught various undergraduate and graduate fundamental engineering and biomedical engineering courses as well as developed new courses for biomedical engineering curricula. She co-authored one textbook and co-edited a book regarding tissue-biomaterial interactions. She has mentored many undergraduate and graduate students, post-doctoral fellows and junior faculty. Her research interests include cellular and tissue engineering, cell interactions with materials, tissue regeneration, biomaterials (including nanostructured ones) and biocompatibility. Professor Bizios’ contributions to education and her research accomplishments have been recognized by several awards at the university, regional, and national levels. She is Fellow of five professional scientific/engineering societies and member of the National Academy of Medicine of the United States and of The Academy of Medicine, Engineering and Science of Texas.
René van Weeren (1957) is a vet by training and earned his PhD degree in 1989 at Utrecht. From 1991-1993 he worked as a visiting professor at the Escuela de Medicina Veterinaria of the Universidad Nacional in Heredia, Costa Rica. He became a diplomate of the European College of Veterinary Surgeons in 1994. He was appointed as full professor to the Chair of Equine Musculoskeletal Biology in 2007. His areas of interest are regenerative medicine of articular cartilage and (equine) biomechanics and especially the cross-roads of these disciplines, i.e. the effects of loading on musculoskeletal tissues, both in mature individuals and during early juvenile development. He collaborates closely with the Medical Faculty and was the first PI of the Veterinary Faculty whose research group was granted a long-term subsidy by the Dutch Arthritis Foundation. René van Weeren has been a supervisor of 31 PhD students and currently supervises 10 others. He is an associate editor of Equine Veterinary Journal, the globally leading equine journal. He is author or co-author of more than 300 peer-reviewed scientific publications and has contributed various chapters to a variety of textbooks. He is one of the editors of the 2nd edition of Joint Disease in the Horse. He is Head of the Department of Equine Sciences of the Faculty of Veterinary Medicine of Utrecht University and interim-head of the Department of Clinical Care of Companion Animals in September 2018.
Ricardo A Pires is graduated in Chemistry from the University of Lisbon (1998). In 2000 he started his PhD studies at the Technical University of Lisbon (IST-UTL) in the development of glass-ionomer cements and their characterization, using nuclear magnetic resonance (NMR) spectroscopy and advanced imaging techniques (concluded in 2004). After completion of his PhD he started to work on an industrial project between the University of Minho (3B’s Research Group) and Corticeira Amorim SGPS, in the establishment of the industrial Department of New Applications and Products based on Cork (February 2005). During this timeframe he developed a series of procedures to extract bioactive natural compounds from different cork-based materials and industrial by-products; work that generated 2 patent applications and several scientific papers. Since 2010 that he is a Senior Researcher at the University of Minho (3B’s Research Group) working in biomaterials, tissue engineering and regenerative medicine. His main research interests are the development of supramolecular hydrogels generated by the self-assembling of short peptide and carbohydrate amphiphiles that can mimic the morphological and biofunctional characteristics of the proteins and proteoglycans present in the extracellular matrix. He is also interested in strategies to modulate protein aggregation driven by self-assembly, e.g. amyloids; the exploitation of nanotechnological tools (e.g. lithography, etc.) in the biomedical area; the development of 2D and 3D cancer models; as well as the development and use of organic and inorganic bionanomaterials, including modified silica-based nanoparticles for stimulation of stem cell differentiation. During his research career he authored 45 papers in international scientific journal with refereeing (list attached; h-index of 14), 4 patents, 6 conference proceedings, 5 book chapters and >85 conference communications. He has published his work in high-impact international journals, such as, Journal of the American Chemical Society, Progress in Polymer Science, Materials Today, Chemical Science, ACS Applied Materials and Interfaces, Acta Biomaterialia, among many others. He already participated in the organization of 12 scientific events (ranging from conferences, workshops and summer schools), from which he co-chaired 4 of them. In addition, he has participated in the execution of medium-sized to very large scientific projects (national and international ones), with a total budget of 12.6M€ assigned to his institution. More info on: https://3bs.uminho.pt/users/rpires
Ricardo Tejero is Head of the Laboratory of Materials Science and Surface Engineering at BTI Biotechnology Institute (Spain). Additionally, he is lecturer in Biomaterials and Biomedical Engineering in the Institute for Regenerative Medicine and Oral Implantology (UIRMI) at University of the Basque Country (UPV-EHU). He holds an Master’s Engineering Degree in Materials Science from the National Institute of Applied Engineering (INSA) of Lyon in France, a Biomaterials Master's Degree from the Dresden University of Technology (TU Dresden), and a Doctor of Biomedicine and Molecular Biology Degree from UPV-EHU awarded with the highest distinction and the Spanish extraordinary PhD prize. Dr. Tejero has conceived and written more than 14 peer-reviewed articles and 6 book chapters. Together with the team, he received the 2016, 2017 and 2018 Asebio award for the Spanish company with highest scientific output. He has participated in 12 patents and is principal inventor of 2. He has been coordinator and/or principal investigator in 16 research projects. He has led the development of more than 15 products in the field of oral implantology, tissue regeneration and surface engineering. His research interests include but are not limited to titanium, blood-plasma-surfaces interactions, implants surfaces chemistry and topography, endogenous regenerative therapies, bioinorganic ions, infective processes, soft and hard tissue regeneration. More information can be found at: https://www.linkedin.com/in/ricardotejero

Riccardo Gottardi, PhD, graduated in 2003 in Applied Physics at the University of Pisa and obtained his PhD in 2007 from the University of Genova (Italy) working on a collaborative project with the Biozentrum of the University Basel (Switzerland, Prof. Ueli Aebi) on atomic force microscopy-based multiscale early diagnosis of osteoarthritis in knee articular cartilage. In 2011 he moved to the University of Pittsburgh thanks to a fellowship from the Ri.MED Foundation to work in the Center for Cellular and Molecular Engineering of the Department of Orthopaedic Surgery with Dr. Rocky S. Tuan, and in the Little Laboratories of the Department of Chemical and Petroleum Engineering with Dr. Steven R. Little. His research focused on tissue engineering/regenerative medicine of cartilage and joint soft tissues and on the application of nanotechnology to drug delivery and cellular guidance for tissue repair. In 2017 he became Research Assistant Professor in the Department of Orthopaedic Surgery of the University of Pittsburgh where he developed innovative synthetic tissue models to study tissue cross talks in health and disease. He was recognized by the Foundation for Women’s Wellness for his research on hormones and osteoarthritis, he led a research effort to study bone loss taking advantage of the unique microgravity environment on the International Space Station, and developed a research program in regenerative rehabilitation, using rehabilitation regimens to mechanobiologically activate and guide joint tissue repair. Since January 2019 Dr. Gottardi is leading the CHOP Bioengineering and Biomaterials laboratory, the first pediatric lab of its kind initiated through the Frontiers Programs. While collaborating on tissue engineering and controlled drug delivery across CHOP, the lab is especially focused on engineering solutions for airway disorders, on biomaterials for laryngotracheal cartilage engineering, and on approaches to prevent and repair damage to the vocal folds.
Riccardo Levato is Assistant Professor of Biofabrication and Regenerative Medicine at the Department of Orthopedics, University Medical Center Utrecht (UMCU) and at the Regenerative Medicine Center Utrecht. His main research focus are on the development of Biofabrication strategies to create bioprinted and lab-made tissue models and transplantable engineered grafts, particularly for osteochondral regeneration. At UMCU, he focuses especially on novel treatments for cartilage and osteochondral defects and their application in translational regenerative medicine. For his work on biofabrication, he was conferred the 2015 Julia Polak award by the European Society for Biomaterials and the 2016 Wake Forest Institute for Regenerative Medicine Young Investigator Award. Dr. Levato worked in several research groups across Europe: 3Bs, University of Minho, (Portugal); BioMatLab, Technical University of Milan (Italy), Institute for Bioengineering of Catalonia (IBEC, Spain), in the field of Biomaterials and Regenerative Medicine, and holds a cum laude PhD in Biomedical Engineering (obtained at the Technical University of Catalonia, Spain).
Roberto Narcisi is Assistant Professor in the department of Orthopaedics at Erasmus MC (Rotterdam, the Netherlands). After the PhD in Biotechnology received from the University of Genova (Italy) in 2011, Roberto Narcisi joined as postdoc the group of Prof. Gerjo van Osch (Erasmus MC) to conduct research on the regulation of chondrogenesis in mesenchymal stem cells (MSCs). Since 2013 his main focus is posed on the use of growth factor-free systems to induce chondrogenic differentiation, and towards the modulation of the WNT and TGFβ signalling to generate stable cartilage in vivo, often taking inspiration from cartilage development. Starting from 2014 he was awarded of 4 personal grants as PI, allowing him to further develop his research line towards a better understanding of the cellular mechanisms driving chondrocytes to acquire a specific phenotype. After a secondment at the Stanford University (California, USA) in 2015, he moved back to the Erasmus MC. He is associate editor of *Frontiers in Bioengineering and Biotechnology*, board member and secretary of the Dutch society for matrix biology (NVMB) and member of the basic science committee of the International Cartilage Regeneration & Joint Preservation Society (ICRS). He is active in science communication activities.
Rocky S Tuan (Ph.D., Rockefeller University) was a professor at the University of Pennsylvania and Thomas Jefferson University, and Chief of the Cartilage Biology and Orthopedics Branch of the NIH, prior to joining the University of Pittsburgh in 2009 as Founding Director, Center for Cellular and Molecular Engineering, and Professor and Executive Vice Chair, Department of Orthopaedic Surgery, and Professor in the Department of Bioengineering. Dr. Tuan was appointed a Distinguished Professor in 2014 and received the Chancellor’s Distinguished Research Award in 2015. In 2018, Prof. Tuan moved to Hong Kong and became the Eighth Vice-Chancellor and President of The Chinese University of Hong Kong, and also founded the Institute for Tissue Engineering and Regenerative Medicine at CUHK. He is a recipient of multiple awards in recognition of his achievements in tissue regenerative science and technologies, including the Marshall Urist Award, Clemson Award, Carnegie Science Award, and was inducted as a Fellow of the National Academy of Inventors in 2017. A prolific author of more than 450 research publications, Prof. Tuan’s multidisciplinary research team focuses on the development, growth, function, and health of the musculoskeletal system, the biology of adult stem cells, and the utilization of this knowledge to develop stem cell- and smart biomaterial-based technologies, such as 3D printing and tissue-on-a-chip, to regenerate and/or restore function to diseased and damaged neuromusculoskeletal tissues.
**Romana Santos**, got her Ph.D. in Biological sciences from the University of Mons, Belgium in 2005. In 2015 she became a researcher at MARE - Marine and Environmental Sciences Centre where she is Principal Investigator since 2017. She has 20 years of experience in sea urchin adhesion using a multidisciplinary approach combining morphology, biomechanics, biochemistry, proteomics, mass spectrometry, transcriptomics and molecular biology. Her research group – BioAdhesion & BioMimicry – aims at characterizing the mechanisms and molecules involved in sea urchin reversible adhesion in order to develop new biomimetic wet-effective, biocompatible, and environmentally safe adhesives for biomedical applications. Bioadhesives are the result of millions of years of evolution and have a huge potential to fulfil the requirements of established and emerging biomedical/biotechnological areas. She has been appointed Vice-Chair of 2 COST Actions - CA15216 “European Network of Bioadhesion Expertise” (2016-2020) and TD0906 “Biological Adhesives: From Biology to Biomimetics” (2010-2014). She also Chaired the 1st International Meeting on Biological and Biomimetic Adhesives in Lisbon, Portugal in 2012, contributing to the creation of a new series of conferences that took place afterwards in Istambul, Turkey in 2014 and Haifa, Israel in 2018. She is also interested in knowledge transfer, being co-founder of the biotech startup BioMimetx SA and co-author of 1 international patent.
Roos Masereeuw (UU) received her PhD from Radboud University in Nijmegen in January 1997. This PhD program and a postdoc period were partly performed at National Institute for Environmental Sciences (NIEHS/NIH), Research Triangle Park, NC, USA. Dr. Masereeuw also visited the NIEHS/NIH institute Mount Desert Island Biological Laboratory (ME, USA) as principal investigator in 1997, 1998, 2010 and 2014. In November 1996, she joined the Dept. of Pharmacology and Toxicology at Radboudumc as assistant professor and in July 2002, she was appointed as associate professor after obtaining an NWO-ASPASIA award. In 2009, she received the Dutch Pharmacological Society (NVF) Schering-Plough Pharmacology Award, in 2010 the Prix Galien Research Award and in 2015 she was elected Fellow of the American Association of Pharmaceutical Scientists. She is currently president of the Dutch Pharmacological Society. Since July 2015 she is full professor of Experimental Pharmacology and since November 2018 director of research at Utrecht Institute for Pharmaceutical Sciences in The Netherlands. Research in the Masereeuw group is focused on developing novel therapeutic strategies to improve organ function in chronic disorders. Her group has developed unique human renal cell lines with a high predictive value for drug transport and metabolism. These cell lines are being used in the development of a bioartificial kidney, organotypic cultures for *in vitro* toxicity testing of chemical entities and drugs in development, and for studying the renal tubular secretion and reabsorption machinery. Roos Masereeuw has (co-)authored over 175 scientific papers, successfully supervised 19 PhD students and currently supervises 11 PhD students and 5 post-docs.
Sally-Ann Cryan is Professor of Drug Delivery, Principal Investigator in the Tissue Engineering Research Group and Research Lead in the School of Pharmacy in the Royal College of Surgeons in Ireland (RCSI). Her research group focuses on translational drug delivery, pharmaceutical engineering and the development of novel materials for healthcare applications. Her team has developed innovative particle engineering strategies for drug targeting tuberculosis, cystic fibrosis and cancer. Her work also includes delivery of therapeutic molecules and cell-based therapies within scaffolds for regenerative medicine applications with a focus on orthopaedic, cardiovascular and respiratory tissue engineering. Working with polymer chemists her team have developed a suite of advanced nanotechnologies and hydrogels for healthcare applications including printable biomaterials. She has filed a number of patent applications and has over 150 publications/presentations in peer-reviewed and professional journals and edited conference proceedings. She works extensively with the pharmaceutical and medical device industry in the areas of drug product development and pharmaceutical technology.
Sandra Hofmann obtained her MSc in Pharmaceutical Sciences from the University of Basel, Switzerland in 2002. After a scientific visit to Prof. David Kaplan’s lab at Tufts University in Boston, she completed her PhD (with distinction) at the Swiss Federal Institute of Technology (ETH) in Zürich in 2007, working on 'silk fibroin as a biomaterial for drug delivery and tissue engineering'. Subsequently, she moved to the group of Prof. Ralph Müller at the ETH's Institute for Biomechanics to focus her studies on imaging methods and bioreactor design. In 2010 Hofmann became group leader of the skeletal tissue engineering group as a senior research associate. Currently, she is an assistant professor in bone tissue engineering (with tenure) at the Orthopaedic Biomechanics group and a core member of the Institute for Complex Molecular Systems (ICMS) at the Eindhoven University of Technology (TU/e). Among others, Sandra Hofmann has obtained an ERC starting grant (2013), a Marie Curie Career integration grant (2013), a Women in Science Grant (2014) and recently she was awarded an NWO Vidi grant (2018).
Sandra van Vlierberghe (10-07-1981) was granted a full-time professorship (100% hoofddocent) at UGent since October 1st, 2017. Her research targets to establish at UGent, “a polymer-based technological platform covering processing and functionalization aspects sufficiently versatile to potentially address a wide range of tissue engineering (TE) challenges by exploiting the unique properties of light.” Indeed, her research focusses on the development of photo-crosslinkable (bio)polymers and their processing capabilities using (laser-based) 3D printing techniques. In addition, she also holds a 20% research professorship at the Faculty of Engineering of the Vrije Universiteit Brussel (VUB). She has acquired expertise related to the synthesis, the modification and the processing (through 3D printing, electrospinning and two-photon polymerization (2PP)) of a variety of (bio)polymers including thermoplasts (e.g. polyesters) and hydrogels (e.g. proteins and polysaccharides) in the field of regenerative medicine during the last 15 years. She graduated as a Master in Chemistry with high distinction with majors in Polymer Chemistry in 2003 and received her PhD in Sciences in 2008, both at Ghent University (UGent). She authored more than 115 Web of Science Core Collection cited papers of which 97 high impact journal papers (one with an impact factor of 33.383) and 11 full papers in international conference proceedings. In addition, she also authored more than 80 conference abstracts. She has a h-index of 24 (WoS) and is promoter of 16 PhD’s (in addition to 7 defended PhD’s), she edited two books, authored 7 chapters in books of which 5 invited and was invited speaker at 10 international conferences and keynote as well as plenary speaker at four international conferences. She is treasurer of the Belgian Polymer Group (BPG), spokesperson of the YSF which is affiliated to the ESB and she is one of the driving forces behind the launch of the ‘Belgian Tissue Engineering Society’ in September this year. Sandra is also editorial board member of the Biomaterials Network, associate editor of Journal of Materials Science: Materials in Medicine, academic guest editor of Materials, editorial advisory board member of Hydrogels and editorial board member of Journal of Nanomedicine and Nanotechnology and Journal of Applied Biomaterials and Functional Materials. The PI has also been active in project reviewing. In 2017, she received the Jean Leray Award from the European Society for Biomaterials. This award is established to recognize outstanding research in the field of biomaterials by scientists not older than 40 years.
Sarah Cartmell is a Professor in Bioengineering at the SoM, UoM. In addition to her Deputy Head of School of Materials role and UK Biomedical Materials champion for The Royce Institute, she has been awarded 48 grants, >£5.8 million of grants as lead PI and >£9.6 million as both PI and CI from 22 different competitive sources ranging from government, charity and industry. She is secretary of the UK Tissue and Cell Engineering Society and an outreach committee member of The Tissue Engineering and Regenerative Medicine International Society; EU chapter. She has over 60 publications with over 3100 citations, 160 published abstracts and has given over 40 invited seminars in the field of tissue engineering and regenerative medicine. All these publications have a common theme of orthopaedic engineering with a particular focus on X-Ray evaluation of tissue engineering constructs and biomaterials and the response of orthopaedic cells to a variety of stimuli such as mechanical forces, electrical stimulus, statins and a variety of different novel materials to support their growth into the correct tissue type SHAPE. She has been a review panel member for the BBSRC, MRC and Innovate UK and has been an external evaluating panel member and UK expert advisor to the European Union as a member of The European Cooperation in the field of Scientific and Technical Research (COST) in the ‘Biomedicine and Molecular Biosciences’ Domain. She is also a reviewer for ERC, EU H2020 Marie Skłodowska Curie Award Individual Fellowships and Integrated Training Networks, Natural Sciences and Engineering Research Council of Canada, Irish Research Council, Czech Science Foundation and Israel Science Foundation. She has been a previous editorial board international member for ‘Biomaterials’ journal and is currently associate editor for ‘Science and Technology of Advanced Materials (STAM)’ and an editorial board member for ‘World Journal of Orthopaedics’.
Scott J Hollister, PhD, is the Patsy and Alan Dorris Chair in Pediatric Technology and a Professor of Biomedical Engineering at the Georgia Institute of Technology. He directs the Center for 3D Medical Fabrication as well as the Tissue Engineering and Mechanics Laboratory at Georgia Tech. Dr. Hollister’s research focuses on the computational design, 3D printing fabrication and characterization of biomaterial devices and scaffolds for tissue reconstruction, specifically in head and neck reconstruction, cardiovascular, and orthopaedic reconstruction applications. He was co-inventor of an airway splint in both resorbable and permanent versions that to date has been implanted and saved the lives of 20 children with Tracheobronchomalacia. This work has been featured in a number of mainstream media outlets including The Today Show, NPR, CNN, the New Yorker, the Doctors Show, CBS Morning News and USA Today. He was awarded the 2013 Popular Mechanics Breakthrough Innovation award for the airway splint together with Dr. Glenn Green.
Shireen Lamandé leads a team at the Murdoch Children’s Research Institute (MCRI) focussed on characterising the molecular and biochemical basis of inherited musculoskeletal disorders, and developing and testing therapies. She graduated with a PhD from the University of Melbourne in 1994 where she identified and characterised collagen I mutations in osteogenesis imperfecta patients and explored the effects of mutations on collagen folding and stability and activation of intracellular quality control pathways. Her interest in extracellular matrix proteins, particularly collagens, and the complex multimeric assembly processes and interactions that underlie the formation of architecturally-precise and tissue-specific extracellular matrices continued throughout her career. Her research program now also includes exploring therapies for muscular dystrophies, identifying new genes and mutations underlying musculoskeletal disorders, and using stem cell models of cartilage and bone disorders to understand pathogenic pathways and test therapies. A/Prof Lamandé held NHMRC Senior Research Fellowships from 2007-2017, served as Vice-President then President of the International Society for Matrix Biology from 2009-2014, and was Vice-President then President of the MBSANZ from 2006-2009.
Siegfried Shah (male) graduated 1994 from the University of Cologne with the license to practice medicine, he completed internships at the Universities of Bologna (Italy), Phoenix (Arizona, USA) and at the Mayo Clinic in Scottsdale (Arizona, USA). After his residency in the surgical department of a major affiliated hospital of the University of Bonn he graduated with the license to practice general surgery. During this time, he completed his doctorate (Dr. med.). After changing to the General- and abdominal surgery department of the University Clinic of Mainz, he was research leader for the experimental evaluation of minimal invasive oncological approaches in a porcine model (AZ 23 177-07/G 07-1-007). Receiving a full license for practicing abdominal surgery he switched 2009 to the Ruhr-University Bochum (RUB), where he was appointed as a surgical consultant for oncological and minimal invasive surgery. Next to his clinical obligations he led the research for intraoperative lymph node mapping and sentinel lymph node identification for histopathological and immunohistochemical examination. Currently, he is leader of the research group investigating genetic polymorphisms of Aquaporins and their influence on outcome in colorectal cancer. At the Centre for Clinical Research (ZKF) he is active for the “Medical Biomaterials” – group as consultant for strategic research decisions and organization. Both, the Aquaporin Polymorphism and the Medical Biomaterials group, are research groups of the Department of Experimental Surgery led by Dr. Jochen Salber. Since Oct. 2018 Dr. S. Shah is head of the Department of Surgery at the St. Marien Hospital Dueren, major affiliated hospital of the University Medical Centre Aachen.
Silvia Farè obtained her Master of Science degree in Management and Industrial Engineering, Politecnico di Milan (IT), in 1994. In 1998, she obtained her PhD degree in Biomaterials (X^ cycle), Politecnico di Milano, with a thesis on the investigation of the mechanisms related to the *in vitro* oxidative degradation of medical-grade polyurethanes. Silvia Farè obtained a Post-doc research Fellowship within the project “Third generation artificial heart” and she was Research Assistant at the Bioengineering Department, Politecnico di Milano. From January 2005 to November 2014, she was Assistant Professor at the Bioengineering Department and at the Department of Chemistry, Materials, and Chemical Engineering “G. Natta”, Politecnico di Milano. From December 2014, she is Associate Professor in Industrial Bioengineering at the Chemistry, Materials and Chemical Engineering, Politecnico di Milano. She was visiting Master and PhD student at the Joint Research Centre, Institute for Advanced Materials, Ispra (VA, Italy), and she was visiting PhD student at the University of Laval and Quebec Biomaterials Institute, Quebec, Canada. She is involved in ESB council from 2017, and President of the Italian Society for Biomaterials (SIB) from 2017. She is Editor-in-chief of the Journal of Applied Biomaterials and Functional Materials (Sage Journals). Her experience focuses on polymers and composites for biomedical applications, in particular for implantable devices, regenerative medicine and tissue engineering applications, 3D-printed biofunctional/smart polymeric in vitro models mimicking muscle-skeletal pathologies, advanced therapies. She is author of more than 80 publications in international peer-reviewed journals, 3 book chapters, more than 100 peer-reviewed conference abstracts and inventor of 3 patents on novel polymer formulation and silk fibroin structure for ligament replacement.
Simon Champ has held a variety of management positions in R&D, marketing and business development in the chemical industry. Dr Champ’s MBA thesis focused on the commercialisation of regenerative medicine technologies. Dr Champ is co-founder of BellaSeno GmbH and Progensis UG (haftungsbeschränkt), a boutique consultancy focusing on the regenerative medicine industry. Dr Champ has decades worth of experience in business strategy, marketing and venture valuation.
Solvig Diederichs, PhD, is an expert in stem cell biology, chondrogenesis and tissue engineering. Since 2013, she is a Principal Investigator at the Research Center for Experimental Orthopaedics at Heidelberg University Hospital, Germany, which she joined in 2008. Trained in induced pluripotent stem cell technology at the Center for Cellular and Molecular Engineering led by Prof. Rocky Tuan, Solvig Diederichs build a research group for stem cell biology at the Research Center for Experimental Orthopaedics in Heidelberg. Headed by Prof. Wiltrud Richter, the Research Center for Experimental Orthopaedics is an internationally acknowledged group dedicated to the development of novel and improved therapies for regeneration of damaged musculoskeletal tissues investigating molecular and cell biological aspects of cartilage and bone regeneration. Solvig Diederichs’ group focuses on induced pluripotent stem cell biology and differentiation and is unique in integrating this novel technology with expertise in cartilage and bone biology, musculoskeletal tissue engineering and in vitro chondrogenesis.
Sonia Fiorilli graduated in Industrial Chemistry at Università di Torino and took her PhD in Materials Science and Technology at Politecnico di Torino in 2005. She is Associate Professor of Fundamentals of Chemical Technology at Politecnico di Torino. Currently, she is Lecturer of “Chemistry” and co-lecturer of “Physical chemistry of materials for nanotechnologies”, at Politecnico di Torino. She has a consolidated expertise concerning the synthesis, characterization and functionalization of inorganic nanostructured materials and bioceramics for application in the biomedical field. Currently, her activity is mainly focused on the development of smart nanomatrices, based on mesoporous silicas and bioactive glasses, for the release of therapeutic agents (ions/drugs) to design advanced multifunctional devices for the treatment of hard and soft tissue pathologies. She is also interested in the development of additive manufacturing processes to produce 3D printed biomimetic scaffolds based on the combination of collagen solutions and inorganic bioactive phases, properly optimized through different cross-linking methods. She is currently involved in the frame of the EU-H2020-MOZART- and she is the principal investigator of the project -ZODIAC- funded by Fondazione San Paolo, in collaboration with Universidad Complutense de Madrid and Nobilbio Ricerche s.r.l. She has published 67 papers in high impact peer-reviewed journals.
Sotiris Korossis, PhD, is the Chair of Biomedical Engineering, Professor of Biomedical Engineering & Biohybrid Organs, and Leader of the Cardiovascular Regenerative Engineering Group at the Centre of Biological Engineering of Loughborough University, and visiting Professor at Hannover Medical School. He is an inventor on three patents, member of two Editorial Boards and past Advanced Research Fellow of the Engineering & Physical Sciences Research Council. He has pioneered research into the fields of tissue engineering of cardiac valves using biological scaffolds and biohybrid extracorporeal membrane oxygenation.
Srinivas Madduri is head, center for bioengineering and regenerative medicine at department of biomedical engineering, University Hospital Basel and University of Basel. He got his PhD in drug delivery and bioengineering in 2010 from ETH Zurich, Switzerland. He was a postdoctoral fellow and research collaborator during 2010 -2015 at University Hospital Zurich, ETH Zurich, Umea University, Barcelona University and University of Turin. His research aims at developing biologically engineered materials for addressing the complex requirements of spatio-temporal cues for repair and regeneration of tissues in the nervous system. His team is comprised of multidisciplinary researchers covering engineers, medical doctors, biologists and material scientists. Madduri has received several research grants from national and international organizations for both preclinical and clinical development of promising therapies. He is an elected board member of European Society for Peripheral Nerve Repair and Reconstruction (ESPNR) and an active member of TERMIS for more than 10 years. Further, he severs for several scientific societies (i.e., CRS, SSBRM, and WBC etc.), grant organizations and research journals covering the filed of regenerative medicine. His research work has been internationally acknowledged with more than 25 number peer-reviewed publications.
Stefan Giselbrecht did his doctorate at the Institute of Microstructure Technology of the Technical University of Karlsruhe, now KIT, and the Institute of Medical Engineering and Biophysics of the Forschungszentrum Karlsruhe (now also KIT) under the supervision of Prof. Volker Saile, and received his Ph.D. degree from the Faculty of Mechanical Engineering. Since 2014, he works at the MERLN Institute for Technology-Inspired Regenerative Medicine as Assistant Professor at the Faculty of Health, Medicine and Life Sciences of Maastricht University. He has published more than 45 peer-reviewed scientific articles and several book chapters. He is also (co-) inventor on more than 10 patents (total number of IPs 50, 14 patent families). Stefan Giselbrecht is founder and CEO of the KIT spin-off 300MICRONS GmbH, which develops and sells innovative 3D cell culture systems and microfluidic bioreactors. Stefan Giselbrecht is interested in developing 3D in vitro models for tissue patterning and morphogenesis. His current research mainly revolves around the development of innovative micro-and nanotechnologies to create complex artificial microenvironments for 3D cultured stem cells and microfluidic systems to control spatiotemporal patterning in stem cell-derived morphogenesis models. He is co-inventor of the SMART-technology (Substrate Modification And Replication by Thermoforming) and has a long-term expertise in producing film-based biomedical microdevices, based on various functionalization methods and microscale thermoforming.
Stelios T Andreadis received his M.S. in Applied Mathematics and Ph.D. in Chemical Engineering from the University of Michigan studying the dynamics of retroviral gene transfer for gene therapy. He then pursued postdoctoral training at the Center for Engineering in Medicine at Harvard Medical School, where he worked in the areas of gene therapy, tissue engineering and regenerative medicine. Currently he serves as SUNY Distinguished Professor of Chemical and Biological Engineering, Biomedical Engineering and Member of the Center of Excellence in Bioinformatics and Life Sciences at the University at Buffalo, State University of New York. He is also the Director of the Stem Cells in Regenerative Medicine (SCiRM) Training Program that was recently funded by NYSTEM to train students in stem cell biology and bioengineering and applications of stem cells in regenerative medicine. He served as CBE department Chair for two terms from 2012 to 2018. His research interests span a wide spectrum from fundamental to technological to pre-clinical/translational studies. He has made significant research contributions in the areas of stem cell bioengineering; vascular, skin and gland tissue engineering and regeneration; molecular design of biomaterials; protein and gene delivery, and lentiviral arrays for high throughput pathway analysis of stem cell differentiation and reprogramming. In 2015 he co-founded a company (Angiograft, LLC) to commercialize the cell-free vascular grafts that were developed in his laboratory as arterial replacement grafts for treatment of cardiovascular disease. Professor Andreadis’ research has received continuous funding since 1999 from NIH, NSF, NYSTEM and private foundations (Whitaker, Oishei), totaling more than $20 million. He is the recipient the Whitaker Foundation Young Investigator Award (1999), the NSF CAREER Award (2000), the Exceptional Scholar Young Investigator Award (UB, 2003), Exceptional Scholar: Sustained Achievement Award (UB, 2009) and the SUNY Chancellor’s Award for Excellence in Scholarship (2014). He was elected to the College of Fellows of the American Institute for Medical and Biological Engineering (AIMBE, 2009) and of the Biomedical Engineering Society (BMES, 2016). In 2018 he was promoted to the rank of SUNY Distinguished Professor. He has published 140 peer-reviewed publications and conference proceedings and delivered more than 75 invited seminars. He has advised 28 Ph.D. students, 18 M.S. students, 4 post-doctoral research fellows and more than 40 undergraduate researchers. His former Ph.D. students hold tenured or tenure-track academic positions (National Institute of Standards and Technology, University of South Florida, University at Buffalo, India Institute of Technology Kanpur, The Capital University of Medical Sciences in Beijing, China); post-doctoral positions at top Universities (Harvard, Stanford, Johns Hopkins, Univ. of Pennsylvania); or research and leadership positions in leading pharmaceutical/biotechnology companies (Shire Pharmaceuticals, Bristol-Myers Squibb, Merck, Biogen, Life Technologies, MedImmune and others).
Stephen Richardson is a Senior Lecturer in Cell and Tissue Engineering, in the Division of Cell Matrix Biology and Regenerative Medicine at The University of Manchester. He is also Programme Director for the Masters in Research (MRes) in Tissue Engineering for Regenerative Medicine and senior tutor for all postgraduate research students in the Division. His research interests are primarily in stem cell biology and application in musculoskeletal tissue engineering/regenerative medicine, with a focus on cell-biomaterial interactions. He also has an interest in modelling intervertebral disc development using iPSCs and developing stem cell-based regenerative therapies for intervertebral disc degeneration. He has published over 50 peer-reviewed papers (h-index=27; >3,500 citations), including publications in internationally-leading journals such as Stem Cells, Biomaterials and JACS, and has successfully obtained grant funding (BBSRC, EPSRC and Arthritis Research UK) totalling over £3M. Dr Richardson was named the NWDA/Nature ‘Northwest Young Biotechnologist of the Year 2006’ and awarded the Tissue and Cell Engineering Society (TCES) ‘Early Stage Investigator Award’ in 2009. He is currently treasurer of Tissue and Cell Engineering Society (TCES) and Programme Chair for the Tissue Engineering and Regenerative Medicine International Society (TERMIS) EU Chapter meeting to be held in Manchester in 2020.
Stephen Rimmer is Professor of Chemistry and Head of the School of Chemistry and Biosciences at the University of Bradford. He was awarded a PhD in 1992 (Imperial College) for work on polyurethane graft copolymers. He spent a total of six years in industrial research and development (Macpherson Polymers Ltd. and Biocompatibles Ltd.) and two years as a post-doctoral fellow with Prof. J. R. Ebdon. His time in industry included development of many commercialised coating formulations and a new contact lens (The ProClear lens). In 1995 he was appointed to a permanent independent post as lecturer at Lancaster University and in 2000 he moved to the University of Sheffield. In January 2012 he was promoted to a personal chair and the took up the Chair of Chemistry at the University of Bradford in May 2015. His research interests can be divided into two main areas: (1) synthesis and (2) biological applications of functional polymers. The group enjoys significant expertise in synthesis by radical, cationic and ring-opening strategies as well as applications that are focused on the use of stimuli responsive polymers, peptide functional polymers, functional hydrogels and production of functional particles. He has published 132 peer-reviewed articles and 12 book chapters and reviews and is inventor on 14 filed patents.
Stina Simonsson (female), principal investigator (PI) and group leader at Clinical Chemistry and Transfusion Medicine at Sahlgrenska Hospital, Institute of Biomedicine at Gothenburg University (UGOT) in Sweden. Her research interests are molecular events in medicine, primarily the rejuvenation of reprogramming of cells. In recent years the main focus has been cartilage repair in relation to osteoarthritis (OA). Simonsson obtained an MSc in Chemical Engineering at Chalmers University of Technology, Sweden in 1992. She received a PhD at UGOT in 2000. The title of her thesis was Initiation of Herpes Simplex Virus DNA Replication. Simonsson went on to do postdoctoral work with Nobel laureate and Lasker Award winner Sir John Gurdon at the University of Cambridge, UK from 2000 to 2005. During her time at the Gurdon Institute, Simonsson made the ground-breaking discovery that epigenetic DNA demethylation and the transcription factor Oct4 controls rejuvenation during SCNT and key for the generation of induced pluripotent stem (iPS) cells. Since 2005 Simonsson has been PI at UGOT Institute of Biomedicine, and she was appointed Associate Professor in Medical Biotechnology in Stem Cell Biology in 2011. Simonsson has managed several international collaborations and receives funding from several major governmental research funding agencies, both in the UK and in Sweden and from EU and she is the UGOT-coordinator and the leader of WP 4 in RESTORE. She is regularly invited to present her research at major scientific meetings and has so far been the main supervisor of three PhD students and some twenty post-doctoral workers.
Stuart B. Goodman is the Robert L. and Mary Ellenburg Professor of Surgery, and Professor with Tenure in the Department of Orthopaedic Surgery at Stanford University. He has a courtesy appointment in the Department of Bioengineering, and is a Fellow of the Institute of Chemistry, Engineering and Medicine for Human Health (ChEM-H). He was Chief of Orthopaedic Surgery at Stanford University from 1994-2002. Dr. Goodman received his BSc, MD and MSc (Institute of Medical Science) from the University of Toronto, and his PhD in Orthopedic Medical Science from Lund University in Sweden. He is a Fellow of the Royal College of Surgeons (Canada), American Academy of Orthopaedic Surgeons and American College of Surgeons. Dr. Goodman was recognized as a Fellow, Biomaterials Science and Engineering (FBSE) by the International Union of Societies, Biomaterials Science and Engineering in May 2004, a Fellow of the Japanese Society of the Promotion of Science in 2011, a Fellow of the American Institute of Medical and Biological Engineers in 2012, and a Fellow of the International Combined Orthopaedic Research Societies in 2016. He was Chairman of the AAOS Biological Implants Committee, and member of the AAOS Biomedical Engineering Committee. He is a member of the Hip Society, Knee Society and AAHKS, a consultant to the FDA Orthopaedic and Rehabilitation Devices Advisory Panel, and former vice-chairman of the Musculoskeletal Tissue Engineering study section at NIH. Dr. Goodman's clinical practice concentrates on adult reconstructive surgery; his clinical research interests include the outcome of surgery for arthritis including primary and revision total joint replacement, juvenile arthritis, and osteonecrosis. His basic science interests center on biocompatibility of orthopaedic implants, inflammation and musculoskeletal tissue regeneration and repair. Dr. Goodman has published over 470 peer-reviewed manuscripts in medical and bioengineering journals. He participates on numerous national and international committees, and editorial boards.
Subhas C. Kundu is now ERA Chair Full Professor, 3Bs Research Group, 13Bs – Institute on Biomaterials, Biodegradables and Biomimetics of University of Minho, Portugal since September 01, 2016. He has obtained his Post-graduation and Ph. D in genetics from Banaras Hindu University, India and received Post-doctoral trainings at Institute of Molecular Biology, Moscow; York University, Canada; Medical University, Lubeck, Germany and Brunel University, UK. Earlier Dr Kundu has been a Full Professor at Department of Biotechnology, Indian Institute of Technology Kharagpur. His research interest has been with silk biomaterial matrices for biomedical applications including cancer 3D modelling for tumor growth, proliferation and drug screening. He has carried out several national and international projects and consultancies. Dr. Kundu is fellow of Alexander von Humboldt, Germany, Association for International Cancer Research, UK, West Bengal Academy of Sciences and The National Academy of Sciences, India; Editorial board members: Biomaterials, Biomedical materials, and Journal of Biological Engineering and others. He has published 174 research articles (h-index 44, Scopus_ID 25647983000) in peer-reviewed journals like Journal of Biological Chemistry, Biomaterials, Biotechnology and Bi oengineering, Acta Biomaterialia, Progress in Polymer Science, Biotechnology Advances, Bio-macromolecules, Advanced Functional Materials, Advanced Materials and others. Present area of interest is natural biomaterials for 3D cancer modelling for drug screening.
Susan Chubinskaya, PhD, the Klaus Kuettner Professor of Osteoarthritis Research, is the Associate Provost for Faculty Affairs at Rush University and Vice-Chair, Research and Faculty Development, Department of Pediatrics. She also holds joint appointments as Professor in the Departments of Internal Medicine and Orthopedic Surgery. In her role as Associate Provost, Susan oversees Faculty Affairs, Faculty Development, Office of Mentoring Programs, and Office of Global Health. Her focus is on faculty database, faculty recruitment and retention, promotion and tenure, professional and career advancement, faculty annual reviews, mentoring, gender equity, diversity and other. Susan is the member of the steering and program subcommittees at the Group on Faculty Affairs at the Association of American Medical Colleges (AAMC). Susan holds leadership positions in other professional societies. Susan is the Board member of the International Cartilage Repair Society (ICRS) and for three years she was a Treasurer and Executive Board member. Susan also serves as the member of the Board of Directors of the Orthopedic Research Society (ORS) and the chair of the ORS Educational Council. She was just elected on the Presidential line of the ORS and will assume the position of the 2nd Vice-President of the ORS in March 2018. In 2020, Susan will become the President of the ORS. As a researcher, she is an internationally recognized expert in the field of cartilage repair/regeneration, especially in post-traumatic and degenerative osteoarthritis. She is a co-recipient of multiple awards. Her research has been continuously funded for over 20 years, she presented more than 240 lectures, published 97 peer-reviewed manuscripts, 12 book chapters, and more than 220 peer-reviewed abstracts.
Susan Gibbs (>150 publications, h-index 30, current research team: 18 scientists) obtained her PhD at Leiden University in 1991. Her entire career has focused on human skin and oral mucosa biology, and in particular in animal alternative methods to develop novel therapeutic strategies for treating and preventing human disease. She became head of the Skin Laboratory, Amsterdam University Medical Centers (location VU University Medical Centre) in 2001. In July 2012, Prof Gibbs’ she was awarded with the Fenna Diemer-Lindeboom chair as Professor of Skin and Mucosa Regenerative Medicine aimed at promoting female scientific talent. This unique position is jointly supported by the Amsterdam UMC and the Academic Centre for Dentistry Amsterdam (ACTA). In 2015, she received the national “Lef in the Lab” prize by the Dutch Animal Protection society for her immune competent skin-on-chip projects.
Sue Kimber is Professor of Stem Cells and Development at the University of Manchester UK. She obtained her BA (Natural Sciences) and PhD from the University of Cambridge UK where she went on to take up a post doctoral position in early mammalian development with Prof Azim Surani FRS. In 2006 she set up the North West Embryonic Stem Cell Centre (NWESCC) with Professor Daniel Brison aimed at deriving embryonic stem cell (hESC) lines suitable for therapy generating 17 lines, 7 at clinical grade now lodged in the UK Stem Cell Bank. The lab has developed advanced protocols for targeting pluripotent stem cell differentiation particularly along mesodermal lineages such as to chondrocytes, nephric progenitors and vascular cells. Using clinical grade hESCs, the chondrogenic protocol is being converted to one suitable for patient therapy with preclinical evaluation including biodistribution and evaluation for absence of tumours. Her lab has also pioneered using patient derived induced pluripotent stem cells for modelling genetic diseases of cartilage and kidney with a view to their application for drug-target discovery. Her work in translating pluripotent and other stem cells for therapeutic purposes formed part of the Innovate funded iMATCH ATTC consortium in Manchester based in the University of Manchester Clean Rooms (Licenced by MHRA for IMPs and Specials including cell and/or gene therapies) which she oversees. She is DI for the University Human Tissue Authority licence for clinical application of human cells and Licence Holder for HFEA licences R0026 and previously R0171 for derivation of human embryonic stem cell lines. Sue is founder and co-Chair of the Mercia Stem Cell Alliance for the promotion of excellence in stem cell science and translation across the North and Midlands in the UK as well as co-Director of the Manchester Regenerative Medicine Network. She is currently Director of the EPSRC/MRC funded Centre for Doctoral Training in Regenerative Medicine in the University of Manchester and a member of the MRC Regenerative Medicine Grant Funding Board.
Susana G Santos is an Assistant Researcher at the Microenvironments for Newtherapies Group, of “Instituto de Investigação e Inovação em Saúde” (i3S) – “Instituto de Engenharia Biomédica” (INEB), Porto, Portugal. She has a PhD in Biomedical Sciences – Immunology, from ICBAS, U. Porto, performed in collaboration with the School of Life Sciences (SLC), U. Dundee, UK. She worked as a Post-doc at U. St Andrews, and as a Medical Research Council-Career Development Fellow at SLC. Since December 2008 she has been at INEB, now integrated in i3S, working on immunomodulatory strategies for tissue repair/regeneration, mostly for osteoarticular applications. She was part of the team awarded the 1st prize Born from Knowledge IDEAS Award 2017, from National Innovation Agency (ANI), Portugal. She is also invited lecturer at U. Porto, teaching at undergraduate and PhD levels, and supervising MSc and PhD students. She participates in science dissemination, particularly for pre-graduate students. Her current research interests are in modulating the crosstalk between immune and tissue/stromal cells, particularly through Extracellular Vesicles, to develop new strategies for tissue repair and regeneration.
Susanne Grässel, Ph.D., is professor at the University of Regensburg in the Dept. of Orthopedic Surgery where she is head of the research group of Experimental Orthopedics since 2003. She is board member of the German Society of Matrix Biology (GSMB) and the president of the Basic Research Section of the German Society of Orthopedic and Trauma Surgery (DGOU). She has published more than 90 peer-reviewed papers, several book chapters, many abstracts and is speaker of the DFG funded Research Consortium ExCarBon (FOR 2704). Her research has been continuously funded over the past 20 years and she has been recipient of several awards during the past years, i.e. the highly priced Basic Science Award of the DGOU for the best paper. Her research started out about collagen structure and function during her postdoc time at Thomas-Jefferson Medical University and became focused from there on cartilage matrix composition and chondrogenic differentiation of MSC. Since her affiliation in Regensburg, she is interested in the basics of disorders of the musculoskeletal system as osteoarthritis and trauma related conditions as bone regeneration in the context of the peripheral nervous system. The research spans from 2D and 3D in vitro models to various in vivo models (transgenic, disease, injury and cell-based therapy models). Translation of basic research questions to clinical applications are the focus of her multidisciplinary team.
Susanne Wolbank, PhD is head of the stem cell biology lab at Ludwig Boltzmann for experimental and clinical Traumatology, Vienna Austria. She is a biotechnologist (University of Natural Resources and Applied Life Sciences, Vienna) and held a postdoc position at the Clinical Research Center, Karolinska Institutet Stockholm on in vitro and in vivo characterization of human embryonic stem cells. She now combines her technological background with her basics knowledge on stem cells to investigate cellular aspects of tissue engineering and regenerative medicine. Her main research interest lies in stem cells from human “waste materials” such as perinatal tissues or adipose tissue. Her work has focused on optimizing these therapeutically relevant cells from isolation to improving the mode of application by activation via shockwave, cell-free application, combination with suitable biomaterials and characterizing these cells including their interaction with other regenerative cell types. She is the current General Secretary of the International Placenta Stem Cell Society (IPLASS).
Tero Järvinen, 47-year old male, is the Chief surgeon and the professor at the department of Orthopedics & Traumatology at the Tampere University Hospital and University of Tampere, Finland. Prof. Järvinen originally graduated from The Medical School, University of Tampere, Finland, in 1997. He received his Ph.D. thesis from the University of Tampere in 1999 and moved into clinical medicine. After the initial period in general surgery, Dr. Järvinen completed his clinical training in orthopaedics and traumatology in 2008. He did his post-doc with the world renowned cell biologist, distinguished professor Erkki Ruoslahti at the Sanford Burnham Prebys Medical Discovery Institute (SBPMDI) at La Jolla, CA, USA in 2003 – 2006. He has published more than 90 peer-reviewed papers. His H-index (Hirsch-index) is 40 and his papers have been cited for almost 6 000 times. Dr. Järvinen has 12 medical patents issued in the USA for his biomedical inventions and has received several international awards. His current research interests are regenerative medicine and sports medicine.
Thomas J. Webster’s (H index: 84) degrees are in chemical engineering from the University of Pittsburgh (B.S., 1995) and in biomedical engineering from Rensselaer Polytechnic Institute (M.S., 1997; Ph.D., 2000). He was appointed Department Chair of Chemical Engineering at Northeastern University in 2012 in which the Department broke the record for the fastest increase in U.S. News and World Report ranking over a five year period. Prof. Webster has graduated/supervised over 149 visiting faculty, clinical fellows, post-doctoral students, and thesis completing B.S., M.S., and Ph.D. students. To date, his lab group has generated over 13 textbooks, 68 book chapters, 376 invited presentations, at least 503 peer-reviewed literature articles and/or conference proceedings, at least 767 conference presentations, and 42 provisional or full patents. He is the founding editor-in-chief of the International Journal of Nanomedicine (pioneering the open-access format). Prof. Webster currently directs or co-directs several centers in the area of biomaterials: The Center for Natural and Tropical Biomaterials (Medellin, Colombia), The Center for Pico and Nanomedicine (Wenzhou China), and The International Materials Research Center (Soochow, China). Prof. Webster has received numerous honors including but not limited to: 2012, Fellow, American Institute for Medical and Biological Engineering (AIMBE, representing the top 2% of all medical and biological engineers); 2013, Fellow, Biomedical Engineering Society; 2015, Wenzhou 580 Award; 2015, Zhejiang 1000 Talent Program; 2016, International Materials Research Chinese Academy of Science Lee-Hsun Lecture Award; 2016, International College of Fellows, Biomaterials Science and Engineering; 2016, Acta Biomaterialia Silver Award; and 2018, Fellow, National Academy of Inventors. He also served as the President of the U.S. Society For Biomaterials. He has appeared on BBC, NBC, ABC, Fox News, the Weather Channel, the Discovery Channel, and the recent special ‘Year Million’ TV series on National Geographic talking about the future of medicine and science.
Thomas Rando, MD, PhD, received his MD and PhD in Cell and Developmental Biology from Harvard University in the USA. After completing clinical training in neurology and postdoctoral training in muscle biology, Dr. Rando was recruited to the faculty of Stanford University in the Department of Neurology and Neurological Sciences, where he is now a full professor. He is also Chief of Neurology at the Veterans Affairs Palo Alto Health Care System when he directs the Center for Tissue Regeneration, Repair, and Restoration (CTR3), a program in regenerative medicine combining expertise in stem cell biology and bioengineering. Dr Rando has been a leader in stem cell biology and his work has focused on both basic research, particularly in the area of stem cell aging and age-related declines in tissue repair, and in the clinical translation for stem cell therapeutics. Dr Rando has received numerous awards including the “Breakthroughs in Gerontology” Award from the American Federation for Aging Research, the NIH Director’s Pioneer Award, and a Transformative Research Award from the NIH. Dr Rando is a member of the National Academy of Medicine and a Fellow of the American Association for the Advancement of Science.
Thorsten Steinberg, PhD, is Associate Professor in Experimental Cell Biology and the Laboratory Head of the Division of Oral Biotechnology in the Center for Dental Medicine of the University Medical Center of Freiburg. His research focus is at the interface between material sciences and biological systems, with the aim to develop and evaluate biomaterials for hard and soft tissue regeneration for different body sites. He is co-inventor of 10 patents around different clinical applications and one of his inventions has been succeeded in a spin-off company in China with the goal to get the regulatory approval for a medical device class III for soft tissue regeneration and here especially for large and full thickness wound situations.
Timothy O’Brien is professor and chair of Medicine and Director of REMEDI at the National University of Ireland (NUI) Galway. He is consultant physician in Endocrinology and Dean of the College of Medicine, Nursing & Health Sciences at the NUI Galway. Prof. Timothy O’Brien trained in internal medicine and endocrinology in Cork, Milwaukee, Rochester and San Francisco. Prior to joining NUI Galway, he worked at Medical College of Wisconsin in Milwaukee, the Mayo Clinic in Rochester, Minnesota and the Gladstone Institute of Cardiovascular Disease at the University of California, San Francisco. In 2001 he was appointed as Head of Medicine at NUI Galway and Consultant Endocrinologist at Galway University Hospital. In 2004 Prof O’Brien established the Regenerative Medicine Institute (REMEDI) at NUI Galway with funding from Science Foundation Ireland and currently holds the position of Director. Research interests include the translation of basic research findings in stem cell biology to regenerative approaches to peripheral vascular disease and diabetic complications in partnership with industry and the health service. He has an active research group at REMEDI NUI Galway investigating the use of mesenchymal stromal cells and endothelial progenitor cells in vascular complications of diabetes mellitus. He is Director of the GMP cell manufacturing facility at NUI Galway and has been a PI on gene therapy and cell therapy clinical trials in Galway. In addition to a laboratory-based programme, his research brings together the Galway HRB Clinical Research Facility, the Galway Blood and Tissue Establishment and the Centre for Cell Manufacturing Ireland for translational research in stem cells and gene therapy. Professor O’Brien has coordinated two EU funded projects; EU FP7 REDDSTAR which is developing and testing a novel stromal cell therapy to treat complications of diabetes mellitus and the recently started EU H2020 NEPHSTROM, which will clinically validate a novel stromal cell therapy for the stabilization of progressive diabetic kidney disease. Prof O’Brien is also funded by SFI/DEL to investigate a combinatorial cell therapy approach to treat critical limb ischemia. Prof O’Brien has a total of 305 publications; with 116 Senior Author Publications; 206 Journal Articles; 75 Reviews and 24 Book Chapters, with a H-Index of 46 (Web of Science).
Uwe Freudenberg is the group leader for matrix engineering at the Institute of Biofunctional Polymer Materials at the Leibniz Institute of Polymer Research Dresden, Germany (IPF). He received his doctoral degree (Dr.-Ing.) from the Faculty of Mechanical Science and Engineering at the Technische Universität Dresden in 2007. His current research focuses on the development of multifunctional polymer materials for biomedical applications with special emphasis on GAG-based hydrogels. He is working on the rational design of hydrogels with variable sulfation pattern for the administration of soluble signaling molecules for application in regenerative medicine. More than 80 ISI indexed publications, 8 patents and h-index: 27, 1800 citations. C-3009-2019, Researcher ID, Web of Science.
Valeria Chiono has a Master Degree in Chemical Engineering summa cum laude (2001) and a PhD in Chemical and Materials Engineering from the University of Pisa, Italy (2006). She is currently Associate Professor at the Department of Mechanical and Aerospace Engineering of Politecnico di Torino, Italy. Her research activity mainly focuses on the development of “bioartificial” materials and biomimetic scaffolds for tissue engineering. She has been the coordinator of several research projects, including a FIRB project financed by the Italian government on the preparation of biomimetic scaffolds for cell therapy using human cardiac progenitor cells. She has also participated to different EU projects, such as Rebiostent project on the development of biomimetic coatings for polymeric stents and HyMedPoly project on the preparation and characterization of intrinsically antibacterial substrates for wound healing. She is currently coordinating the ERC Consolidator project BIORECAR (contract number: 772168) on advanced strategies for heart regeneration, through direct reprogramming of human cardiac fibroblasts into cardiomyocytes exploiting a multifunctional biomaterial platform. She is author of more than 85 manuscripts (H-index: 26; Scopus Source) and 4 patents in the field of biomaterials and tissue engineering.
Valerian E Kagan is one of the world’s recognized leaders and one of the most prominent authorities in the field of Free Radical Biology and Medicine. Internationally known for his interdisciplinary studies of oxidative stress, antioxidants, tissue and cell acute and chronic injury, he is one of the leaders in the new field of “Oxidative Lipidomics”. He has demonstrated its research power in investigations of cell death mechanisms. Free radicals, lipid peroxidation and oxidative stress have been long associated with tissue and cell damage through yet not well characterized specific mechanisms. The incompleteness of this knowledge is a stumbling block in discovery, development and effective implementation of antioxidant preventive and therapeutic strategies. The research performed by Dr. Kagan is important as it uncovers specific pathways through which enzymes of oxidative metabolism participate in the production of specific oxygenated lipid molecules that act as signals triggering cell death programs as well as mechanisms involved in clearance of damaged or dead cells. As an outstanding biochemist, redox biologist, molecular pharmacologist and toxicologist, Dr. Kagan has published more than 600 peer-reviewed papers, including many in the most prestigious journals (with impact factors in the range of 10-30) such as Cell, Nature, Nature Medicine, Nature Cell Biology, PNAS, etc.
Valérie Geoffroy got her Ph.D. in Molecular and Cellular Pharmacology from the University of Paris, France, in 1996. Valérie Geoffroy is director of research, deputy head of the team “Regenerative medicine of bone tissues” and the leader of the group “Molecular control of bone aging and regeneration” at Inserm U1229-RMeS in Nantes, France. Valérie Geoffroy is an expert in the mechanisms of bone formation and remodeling in the mineralized tissues research field and in the regulation of gene expression. She has spent 15 years deciphering the part of Runx2 in bone formation and remodeling. She published the first evidence that Runx2 is the key factor of bone development and osteoblast differentiation \textit{in vivo}. More recently, she identified a new alternative for the regulation of osteoblast differentiation, involving miRNAs. She is now developing a new research theme focusing on the molecular control of bone ageing and regeneration. Her group investigates novel mechanisms of osteoformation and target molecules that contribute to stem cell reprogramming.
Vanesa Alonso-Camino holds a master’s degree in molecular and cellular biology and a Ph.D. in molecular immunology and immunotherapy. She currently works as a senior scientist and R&D lead at Mill Creek Life Sciences, a biotech company located in Rochester, Minnesota (USA). During her postgraduate and postdoctoral years she worked in numerous projects related to biologic therapies of cancer, including recombinant antibody therapies, cell based therapies and cancer virotherapy. Dr. Alonso-Camino has over 14 years of experience on cell culture and molecular Biology, animal model development and drug discovery. She has been working at Mill Creek Life Sciences for almost 4 years on drug development, product release testing, training personnel and implementing procedures performed under GMP conditions. She also develops and manages R&D projects related to regenerative medicine and cancer immunotherapy.
Véronique Lefebvre, PhD, is a Research Professor of Orthopaedic Surgery, in the Translational Program in Pediatric Orthopaedics at the Children’s Hospital of Philadelphia and University of Pennsylvania, USA. She has committed her research career to deciphering molecular mechanisms that specify the fate and identity of stem cells and differentiated cell types in the skeletal system. She has chiefly contributed to discovering the key roles that several members of the SOX transcription factor family have in this system. These include evidence that SOX9 is a master regulator of chondrogenesis and works in partnership with SOX5 and SOX6, and that SOX4 and SOX11 are pivotal determinants of stem/progenitor cell survival and fate determination in skeletal and other lineages. Current efforts in her laboratory focus on the modes of action and regulation of SOX genes in the normal processes of skeleton development and adult homeostasis and in such severe pathologies as skeletal dysplasias and joint degeneration diseases in humans. She has published in high-impact scientific journals and has received invitations to speak at prestigious conferences worldwide. She has been continuously supported by grants and awards from the National Institutes of Health and research foundations, and regularly serves on study sections for the like. Her scientific community services include the organization and chairing of conferences, such as the 2014 International SOX Research Conference and the 2015 Gordon Research Conference on Cartilage Biology and Pathology. Last but not least, she is a strong believer that career success is measured not merely by personal research accomplishments but most effectively and most gratifyingly by multi-team collaborations and by mentoring and motivating the younger generations of research and clinician scientists.
Vladimir Mironov was born in Russia in 1954. Vladimir Mironov finished Ivanovo State Medical Institute in 1977 as a medical doctor. He got his PhD in Developmental Biology from Second Moscow Pirogov Medical Institute in 1980. He was trained by Prof. Peter Kaufmann at The Department of Anatomy RWTH in Aachen and Werner Risau's lab in Germany in Max Planck Institute for Psychiatry in Matsinsried, Germany. He later worked at The Department of Anatomy and Regenerative Medicine and Advanced Tissue Biofabrication Center in The Medical University of South Carolina in Charleston, SC, USA and then at The Division of 3D Technologies of Renato Archer Institute for InformationTechnology at Campinas, SP, Brazil. Last 5 years he worked as a Chief Scientific Officer at 3D Bioprinting Solutions and Leading Scientist at Regenerative Medicine institute of Moscow Sechenov Medical University, Moscow, Russia. He is one of pioneer of 3D bioprinting technology. He already bioprinted a first functional and vascularised organ construct - a mouse thyroid gland.
Walter Brehm, DVM, Dr.med.vet., Dr.habil., DECVS, is a diplomate specialist in veterinary surgery, a professor of large animal surgery and the director of the Department for Horses at the Faculty of Veterinary Medicine of the University of Leipzig. He received his Dr.med.vet. degree in 1991 at Ludwig-Maximilians-Universität München after the preparation of a thesis at the Institute of Animal Nutrition chaired by Prof. Hermann Zucker. Walter Brehm was a resident/intern at the Clinic for Horses, General Surgery and Radiology at the Free University of Berlin from 1993 until 1998 and the head of equine surgery at the Equine Clinic of the University of Bern, Switzerland from 1999 until 2007. He received his german board certification in equine medicine (Fachtierarzt für Pferde) in 1997 as well as the status of a diplomate of the European College of Veterinary Surgeons in 2002. Together with his habilitation on “steps towards cartilage repair with scaffold-free engineered autologous cartilage constructs” at the University of Bern, Switzerland, he received the venia legendi for equine medicine and large animal surgery in 2007. The major area of research of Walter Brehm is the use of stem cells for the treatment of orthopaedic conditions in the horse. This includes the diagnostics of orthopaedic conditions as well as the therapeutical application of stem cells and above this, more basic investigations into the biology of equine stem cells and the development of suitable in vitro and in vivo models. Prof. Brehm is a founding member of the International Veterinary Regenerative Medicine Society IVRMS, now a chapter of TERMIS, and member of the board of directors of the Saxonian Incubator for Clinical Translation (former Translational Center for Regenerative Medicine) at the University of Leipzig as well as a member of several professional associations. For publications go to: https://www.researchgate.net/profile/Walter_Brehm2
Wei Zuo, PhD, is the Chair of Kiangnan Stem cell Institute, Professor at Tongji University, Principal Investigator at Shanghai Pulmonary Hospital and Founder of Regend Therapeutics Ltd in China. He has pioneered research into adult epithelial stem cells and organ regeneration. He discovered the distal airway stem cells in adult mouse and human lungs, and invented the intrapulmonary stem cell transplantation technology. Based on autologous distal airway stem cell transplantation, he launched the first registered lung regeneration clinical trial. He also has interest in cloning adult stem cells from multiple different tissues including kidney, liver and uterus, as well as genetic engineering of such stem cells to build bioengineered organs.
Wenxin Wang is a Professor in wound healing and skin research and Science Foundation Ireland (SFI) Principle Investigator at Charles Institute of Dermatology, School of Medicine, University College Dublin (UCD), Ireland. His scientific interests are in the areas of skin wound healing, gene therapy, and development of new treatments for cardiovascular and neural degenerative disease. His scientific contributions and achievements, which have been widely recognized, include 4 book chapters, 14 granted patents, 3 filed patent applications, and 169 peer-reviewed journal publications including Nature Communications, Science Advances, JACS, Angewandte Chemie, and Advanced Materials. Professor Wang has been invited 70 times as a keynote or invited speaker at international conferences and universities. He has hosted 20 conferences as a member of the advisory board, organizer, chair or convener around the world. As the founder, Prof Wang has launched two spin-out companies - Vornia Ltd (www.vornia.com, sold to Ashland – a Fortune500 US company) and Blafar Ltd (www.blafar.com). Furthermore, he has licensed 4 new technologies to four companies.
Wojciech Swieszkowski is a professor at Faculty of Materials Science and Engineering, Warsaw University of Technology (WUT), POLAND. He received PhD in biomechanics and Habilitation in Materials Science and Engineering at WUT. He did his 4-year PostDoc at Delft University of Technology. He was visiting professor at several universities, such as Harvard University, NIMS Japan, or TU Vienna. He is an expert in the field of biofabrication and bioprinting, biomaterials for implants and tissue engineering, computational modeling and characterization of materials. He leads BioMaterials Group (9 post doctorate and 10 PhD students, www.bio.materials.pl). He has been leader and project manager of 10 international and 15 national projects with total funding > 10M EURO. He plays a role of Director of Materials Design Division and he acts as a Faculty Coordinator of ERASMUS Program. He has been an author of more than 100 publications, 16 book chapters and 9 patents, over 2000 citations. He was a laureate of several awards including 1st Prize of Prime Minister of Poland (2001) and Prizes from the Rector of the Warsaw University of Technology for scientific achievement (2011, 2012, 2013, 2014).
Wolfgang Holnthoner obtained his MSc in Microbiology and Genetics and his PhD in Molecular Biology, both from the University of Vienna, Austria. For more than 17 years, he has been working on endothelial cells, both from blood and lymphatic vessel origin. After his postdoctoral training with Kari Alitalo at the University of Helsinki, Finland, where he had been exploring signal transduction in lymphatic endothelial cells, he started at the Ludwig-Boltzmann-Institute for Experimental and Clinical Traumatology to work on strategies for prevascularisation of tissue engineered constructs. He is interested in the basic functions of endothelial cells in vasculogenesis, angiogenesis and lymphangiogenesis. His group's primary focus is the regeneration/engineering of microvascular structures. To this aim, he employs co-culturing primary endothelial cells with supporting cell types to achieve functional oxygen and nutrient support of tissues. He uses the physiological and biocompatible scaffold fibrin to provide the cells the necessary 3D-environment for microvascularization. In addition, his research involves the integration of lymphatic vessels, since they are the ones, which transport the interstitial fluid in tissues back to the blood circulation, and without them human life would be inconceivable. Moreover, he strives to explore the emerging role of extracellular vesicles (EV) in intercellular communication. These efforts contribute to the development of therapies aimed for regeneration of diseased tissues.
Xiao-nong Wang is a Senior Lecturer in Cell Therapy & Transplantation Immunology, a principle investigator in the Regenerative Medicine & Transplantation Group at Newcastle University, UK. She has over 20 years experience in developing stratified therapy using cells, biologics or innovative medical devices for prevention and treatment of inflammatory immune responses associated with complications of allogeneic transplantations. She has authored over 100 peer-reviewed publications in the leading scientific journals in the Stem Cell, Immunology, Transplantation, and Regenerative Medicine fields. Over the last decade her research has been investigating the mechanisms of action and therapeutic potential of human regulatory T cells and mesenchymal stromal cells in immunomodulation and regenerative medicine, with an increasing focus on exploring extracellular vesicles secreted by mesenchymal stromal cells as an innovative regenerative medicine approach for enhancing osteoarthritic joint tissue repair/regeneration. Her research has been supported by the EC-FP7, FP6, and FP5, Arthritis Research UK and Local Healthcare Charities.
Xuebin Yang (XY), the head of tissue engineering research at School of Dentistry, University of Leeds, UK, is also a ‘Concurrent Professor’ in Nanjing University, China (2009-), ‘Invited Professor’ in Tokyo Women’s Medical University, Japan (2011-), ‘Honorary Professor’ in School of Medicine, Henan University of Science and Technology, China (2012-), and a ‘Visiting Professor’ in CDRSP, Polytechnic Institute of Leiria, Portugal. His research profile combines 12 years’ expertise in clinical orthopaedics with highly specialised research expertises (Since 1999) in skeletal tissue engineering using stem cell therapy, biomimetic biomaterials and in vitro, in vivo models. Originally an orthopaedic surgeon, XY completed his primary medical education in 1984. Subsequently, he was awarded an MSc degree in hand and microsurgery (1992, Fudan University) and a PhD degree in bone tissue engineering (2002, University of Southampton). XY has supervised over 6 MSc and 22 PhD students to completion. He is currently leading a team of 12 PhD students who are working on stem cell therapy and skeletal tissue engineering in regenerative medicine and dentistry. XY holds a Home Office Project License for 8 different in vivo models for pre-clinical testing of the efficacy of stem cell therapy and/or biomaterial scaffolds. He plays a key role in the University’s major tissue engineering and regenerative medicine research programmes (WELMEC, CDT, LMBRU and Regener8). He developed and provide leadership (PIs) for six international consortia which include partners in USA, Japan, New Zealand, China, Australia and EU countries. XY has been the Honorary Treasurer and Trustee of the British Orthopaedic Research Society, the vice-president of the Luoyang Hand Surgery Society, a member of the scientific committees for many prestigious conferences, grant review panels (e.g. FP7, Horizon 2020, NSFC) and editorial board for professional journals.
Yasuhiko Tabata is the Professor and Chairman of the Laboratory of Biomaterials at the Institute for Frontier Life and Medical Sciences, Kyoto University and a Professor of the Graduate School of Medicine, Osaka University, and guest professors at the Graduate School of Medicine, Dentistry, Pharmaceutical Sciences, and Engineering of 17 different universities. He received his BD in Polymer Chemistry (1981), Ph.D. (1988) in Technology, D.Med.Sc. (2002), and D.Pharm. (2003) all at Kyoto University. He was a Visiting Scientist at the MIT (Professor Robert Langer) (1991-92). He has published 1,550 scientific papers including 120 book chapters and review articles, and has 140 patents. He received the Young Investigator Award (1990), the Scientific Award from the Japanese Society for Biomaterials (2002), the Scientific Award from the Japan Society of Drug Delivery System (2011), Chandra P. Sharma Award of the International Society of Biomaterials & Artificial Organs (2011), the Scientific Award from the Japanese Society for Regenerative Medicine (2014), Merit Award Winners for Industry-Academia-Government Collaboration, President of Science Council of Japan Award (2016), and several awards. Dr. Tabata is the board member of the Japanese Society of Regenerative Medicine (JSRM), the Japanese Society for Biomaterials (JSB), the Japan Society of Drug Delivery System (JSDDS), and the Japanese Society of Inflammation and Regeneration (JSIR) or the councilor of the Japanese Society of Wound Healing, the Japanese Artificial Organ Society. He is an associate member of the Science Council of Japan, Cabinet Office, a fellow of the New York Academy of Science and American Institute for Medical and Biological Engineering (AIMBE), and the Founding Fellow for Tissue Engineering and Regenerative Medicine (FTERM). He is a board member of TERMIS-AP for 2013-present and the president of TERMIS-AP for 2016-2020, and will chair the 5th TERMIS World Congress 2018, Kyoto, Japan.
Ying Yang is a Professor in Biomaterials and Tissue engineering at Keele University, UK. She has substantial experience in tissue model construction and maturation for multiple tissues cornea, tendon, bone, cartilage, blood vessel, nerve and lung. Her core research interests are using biomaterial and culture environments as tools to develop new strategies in regenerative medicine, and explore various new imaging modalities to monitor tissue development process. She has paid great attention on cellular response to scaffold or substrate’s composition and topographic influence. These experiences are directly relevant to the heterogeneous tissue formation. In addition, she has accumulated great experience of using imaging techniques, e.g. optical coherence tomography, FTIR, fluorescence in tissue engineering field and disease diagnosis. Her research is supported by UK research council, EU and various charity organizations.
Yoshihiro Ito received his Bachelor’s (1981) and Master’s (1983) degrees in polymer chemistry at Kyoto University and was awarded a doctorate in engineering from the same university in 1987. Since then he has held a number of posts at various institutions including an assistant (1988) and associate (1996) professor at Kyoto University, research fellow at the University of California, Irvine (1992–1993), professor of the University of Tokushima (1999). Now, he is Chief Scientist and Director of the Nano Medical Engineering Laboratory at the RIKEN (from 2004) and a team leader of Emergent Bioengineering Materials Research Team, RIKEN Center for Emergent Matter Science (from 2013). He has also visiting professor positions in Tokyo Metropolitan University, Tokyo Institute of Technology, Hokkaido University, Waseda University, and Nagoya University and is the guest professor of Changchun Institute of Applied Chemistry, Chinese Academy of Sciences. He received the Award of Japanese Society of Biomaterials (2009), Fellow of International Union of Biomaterials Science and Engineering (2012), and Significant Achievement Award from RIKEN (2013). His research focuses on biomaterial science, regenerative medical engineering, combinatorial bioengineering for the creation of functional polymers, and soft nanotechnology.
Yu Shrike Zhang is an Assistant Professor of Medicine at Harvard Medical School and Associate Bioengineer at the Brigham and Women’s Hospital. Dr. Zhang’s research is focused on innovating medical engineering technologies, including 3D bioprinting, organs-on-chips, microfluidics, biomedical imaging, and biosensing, to recreate functional tissues and their biomimetic models in the aim of promoting personalizable medicine. He is an author of more than 140 peer-reviewed publications and his scientific contributions have been recognized by 40 international, national, and regional awards. More information can be read on his website (www.shrikezhang.com).
Yury Rochev obtained a Specialist Degree in Physics (Diploma with Honors) (1984) at Moscow State University, Biophysical Department, Soviet Union. He worked at the Institute of Biological Physics at the Soviet Academy of Science. In 1990 he was awarded a Doctorate in Biophysics from the Institute of Biological Physics, the Soviet Academy of Science. Dr. Yury Rochev joined the National Centre for Biomedical Engineering Science, Galway, Ireland in 2002, as Senior Scientist in the Biomaterials Cluster. Dr. Yury Rochev’s current main research interests include (1) cell-biomaterial interactions, fundamental aspects of biocompatibility; (2) tissue engineering; (3) drug delivery. He has published over 100 peer-reviewed journal articles and has contributed chapters to 7 books. Dr. Rochev has been involved in several national and European collaborative research projects in biomaterials, tissue engineering, regenerative medicine and translation medicine. Dr. Rochev is currently involved in a number of industrial research collaborations, including a major collaborative research program with Boston Scientific Ireland. Dr. Rochev is an affiliated chief researcher at the Institute of Regenerative Medicine at the Sechenov First Moscow State Medical University.
Yvonne Bastiaansen-Jenniskens obtained her PhD in 2009 in cartilage tissue engineering and repair at the Erasmus University Rotterdam, the Netherlands. After that, her research shifted to examining the involvement of macrophages in orthopedic (related) topics. Her research group is investigating the involvement of macrophages in osteoarthritic processes and cartilage repair using mouse models, and several in vitro models involving macrophages and other tissue and cell types. In all of the above-described projects, she is also investigating the possibility to modulate macrophage phenotypes aiming to inhibit inflammation and osteoarthritis progression, and promote tissue repair. She received a Veni grant from the Netherlands Organisation for Scientific Research (NWO) and a fellowship from the Erasmus MC.

In silico regenerative medicine: from living implants to digital patients
Liesbet Geris
Presenting Author: Liesbet Geris, liesbet.geris@uliege.be
Prometheus, R&D Division for Skeletal Tissue Engineering, KU Leuven, Belgium. GIGA In silico medicine, University of Liège, Belgium. Biomechanics Section, KU Leuven, Belgium

As basic science advances, one of the major challenges in Tissue Engineering (TE) is the translation of the increasing biological knowledge on complex cell and tissue behavior into predictive and robust engineering processes. Mastering this complexity is an essential step towards clinical translation of TE applications. Computational (in silico) modeling allows to study the biological complexity in a more integrative and quantitative way. Specifically, in silico and in vitro tools can help in quantifying and optimizing the TE products and processes but also in assessing the influence of the in vivo environment on the behavior of the TE products after implantation. We develop computational models related to all aspects of the TE product development cycle. Depending on the specific questions that need to be answered and on the available information, model systems can be purely data-driven or more hypothesis-driven in nature. At cell level we study cellular regulation through knowledge-based and multi-omics approaches (transcriptomics & metabolomics). For carriers, we use models that combine effects of geometry, composition and degradation on tissue growth to optimize scaffolds printed in a variety of materials. With respect to culture strategies, we combine the development of in vitro set-ups (e.g. stand-alone perfusion bioreactor) with their digital twins. For a prediction of in vivo processes (clinical), we look at normal and pathophysiological healing cases and design possible treatment strategies that we test in in silico clinical trials. To bring these models to the clinics and/or the market, various collaborations have been set up with clinicians and companies, in Belgium and Europe. An important prerequisite to this translation is the acceptance of digital evidence generated by in silico tools in biomedical R&D activities and in regulatory submissions to EMA and USA-FDA (the latter is a driver of the use of in silico tools). Through our involvement in the Virtual Physiological Human institute and the Avicenna Alliance, we are involved in interactions with a variety of stakeholders, including policy makers and regulators across the world, to establish proper policies, regulations and harmonized guidelines related to the use of in silico tools in medicinal product development & translation.

ACKNOWLEDGEMENTS: A big thank you to all current & former members of the Biomechanics Research Unit (U Liège/KU Leuven) & Prome-theus. Funding gratefully acknowledged from ERC CoG, INTERREG VL-NL, MSCA-ITN, BIOWIN, FNRS, REGMED XB, fond. Francqui & FWO.

My career: A lifetime of TERM research and innovation & a lifer of TERMIS

Rui L. Reis 1,2,3

Presenting Author: Rui L. Reis, rgreis@i3bs.uminho.pt

13B’s Research Group, I3Bs – Research Institute on Biomaterials, Biodegradables and Biomimetics, University of Minho, Headquarters of the European Institute of Excellence on Tissue Engineering and Regenerative Medicine, AvePark, Parque de Ciência e Tecnologia, Zona Industrial da Gandra, 4805-017 Barco, Guimarães, Portugal 2ICVS/3B’s–PT Government Associate Laboratory, Braga/Guimarães, Portugal 3The Discoveries Centre for Regenerative and Precision Medicine, Headquarters at University of Minho, Avepark, 4805-017 Barco, Guimarães, Portugal

In this talk, as it is typical for such kind of lifetime achievement award, I will describe my career as researcher and innovator in the field of tissue engineering and regenerative medicine (TERM) and my involvement with and contributions to TERMIS and the field as a whole along the years. I will of course present some examples of my own research. The selection of a proper material to be used as a scaffold or as a hydrogel to support, hold or encapsulate cells is both a critical and a difficult choice that will determine the success of failure of any TERM strategy. We believe that the use of natural origin polymers, including a wide range of marine origin materials, is the best option for many different approaches that allow for the regeneration of different tissues. In addition to the selection of appropriate material systems it is of utmost importance the development of processing methodologies that allow for the production of adequate scaffolds/matrices, in many cases incorporating bioactive/differentiation agents in their structures. Furthermore, an adequate cell source should be selected. In many cases efficient cell isolation, expansion and differentiation, and in many cases the selection of a specific sub-population, methodologies should be developed and optimized. The development of dynamic ways to culture the cells and of distinct ways to stimulate their differentiation in 3D environments, as well as the use of nano-based systems to induce their differentiation and internalization into cells, is also a key part of some of the strategies that are being developed in our research group. The potential of each combination materials/cells, to be used to develop novel useful regeneration therapies will be discussed. The use of different cells and their interactions with different natural origin degradable scaffolds and smart hydrogels will be described. Several examples of TERM strategies to regenerate different types of tissues will be presented. It has been my honor to serve TERMIS in different leadership roles since its foundation. I have participated in almost every meeting of all chapters of our Society. I will also describe those roles and my involvement with the society along the years, as well as my present responsibilities in TERMIS. I was and I am a lifer of TERMIS!
Towards the end of a career, some people should be encouraged to fade away gently, having little more constructive to say as the world moves on apace. Others have every right to shout out their views until quietened by death. Dylan Thomas was very upset by the late-life quieting of his father and would have preferred that he stay angry; “Rage, rage, against the dying of the light”. Both are valid positions and while I tend to favour the latter, I have much sympathy with the words of Archbishop Desmond Tutu; “Don’t raise your voice, improve your argument”. For many years I have argued that our understanding of mechanisms of biocompatibility has been based on false assumptions. I have written many papers on this subject, drawing attention to two main consequences of these misconceptions; first the continued belief that biocompatibility is a property of a biomaterial rather than of a biomaterial-host system, and secondly that one of the most important specifications of a tissue-engineering biomaterial is prior approval by the FDA for use in an implantable medical device. These views lead to erroneous descriptions of materials as being ‘biocompatible’ and to the use of some degradable synthetic polymers as scaffolds when they have no chance of success. I will not raise my voice here but improve my arguments, based on theory, experiment and clinical experience, to show that a major change in our understanding of biocompatibility mechanisms and in our practices of testing the biosafety of biomaterials, should lead to better success in these potentially valuable components of medical technology. To combine Desmond and Dylan, let us “improve our arguments as we go into that good night”.

Department of Bioengineering, Rice University, Houston, Texas, United States of America

Advances in biology, materials science, chemical engineering, and other fields have allowed for the development of tissue engineering, an interdisciplinary convergence science. For the past two and a half decades, our laboratory has focused on the development and characterization of biomaterials-based strategies for the regeneration of human tissues with the goal of improving healthcare outcomes. In a collaborative effort with physicians, surgeons, and other scientists, we have produced new material compositions and three-dimensional scaffolds, and investigated combinations of biomaterials with cell populations and bioactive agents for their ability to induce tissue formation and regeneration. We have examined the effects of material characteristics, such as mechanical properties, topographical features, and functional groups, on cell behavior and tissue guidance, and leveraged biomaterials as drug delivery vehicles to release growth factors and other signals with spatial and temporal specificity. This presentation will review recent examples of biomaterials-based approaches for regenerative medicine applications and highlight future areas of growth, such as the use of tissue engineering to model tumor microenvironments for validation of cancer therapeutic discovery.
Magnetically assisted tissue engineering technologies for tendon regeneration
Manuela E. Gomes¹,²,³

The poor healing ability of tendons, which play a critical role in the musculoskeletal system, as well as the limitations of currently used therapies have motivated tissue engineering (TE) strategies to develop living tendon substitutes. However, the limited knowledge on tendon development and healing processes has hindered the design of TE procedures that more closely recapitulate tendon morphogenesis. Therefore, we’ve been exploring conventional and innovative tools to design magnetic responsive systems mimicking specific aspects of tendon tissue architecture, composition and biomechanical properties, which, combined with adequate stem cells, are expected to render appropriate behavioral instructions to stimulate the regeneration of tendon tissue. Stem cell bioengineering approaches based on superparamagnetic nanoparticles (SPMNs), are being used to unveil the cellular signaling pathways that trigger the tenogenic differentiation of the widely and easily obtained human adipose derived stem cells. Simultaneously, efforts have also focused on understanding possible uses of magnetic stimulus, in combination with magnetic responsive materials, to modulate inflammation in tendon/tendon cells, which can provide an additional valuable tool to trigger tissue regeneration instead of simple repair.

Medical School, University of Crete, Heraklion, Crete, Greece

Autophagy is crucial for neuronal integrity. Loss of key autophagic components leads to progressive neurodegeneration and structural defects in neuronal synapses. However, the molecular mechanisms regulating autophagy in the brain remain elusive. Similarly, while it is widely accepted that protein turnover is required for synaptic plasticity, the contribution of autophagy to the degradation of synaptic proteins is unknown. We find that BDNF signaling via the tropomyosin receptor kinase B (TrkB) and the phosphatidylinositol-3 kinase (PI3K)/Akt pathway suppresses autophagy in vivo. Autophagy is differentially regulated by fasting in different brain regions. Suppression of autophagy is required for BDNF-induced synaptic plasticity and for memory enhancement, under conditions of nutritional stress. BDNF signaling suppresses autophagy in the forebrain of adult mice. Indeed, BDNF ablation in the neural lineage causes uncontrolled increase in autophagy. In turn, increased autophagy mediates the synaptic defects caused by BDNF deficiency. Thus, fasting suppresses autophagy in regions of the mouse forebrain, thereby promoting synaptic remodeling and memory through a BDNF-regulated mechanism. We identify three key remodelers of postsynaptic densities as cargo of autophagy. Our results establish autophagy as a pivotal component of BDNF signaling, which is essential for BDNF-induced synaptic plasticity. This molecular mechanism underlies behavioral adaptations that increase fitness in times of scarcity.
Vascular endothelial growth factors. From basic science to clinical trials
Seppo Yla-Herttuala\textsuperscript{1,2}

Therapeutic vascular growth is a potentially useful strategy for ischemic heart disease and peripheral arterial occlusive disease. It involves generation of new capillaries, collateral vessels and lymphatic vessels in ischaemic muscles using either recombinant growth factors or their genes. Arteriogenesis is a process caused by increased sheer stress at the arteriolar level resulting in the formation of large conduit vessels from preexisting small vessels whereas angiogenesis and lymphangiogenesis refers to generation of new vascular structures in vivo. Most commonly used growth factors for therapeutic angiogenesis are members of the vascular endothelial growth factor (VEGF) and fibroblast growth factor (FGF) families. Some other cytokines and growth factors can also have angiogenic effects. Improved perfusion and functional parameters can be achieved by angiogenesis and arteriogenesis in large animal chronic ischemia models and in man. Safety of the clinical gene therapy of cardiovascular diseases has been excellent with long-term follow-up to 10 yrs after the therapy. Small non-coding RNAs can also be used for angiogenic gene therapy. Most promising results have so far been obtained with direct catheter-based intramyocardial injections of VEGF-D genes with adenovirus and AAV vectors.

Polymeric nanoparticles for the intracellular delivery of biotherapeutics for cancer treatment
Wim E. Hennink
Presenting Author: Wim E Hennink, W.E.Hennink@uu.nl
Department of Pharmaceutics, Utrecht Institute for Pharmaceutical Sciences, Utrecht University, Utrecht, The Netherlands

An attractive approach to induce a strong immune response against a certain antigen is its targeting to dendritic cells (DCs). Targeting can be established by loading the antigen in a nano-sized carrier and keeping the antigen encapsulated or associated with the particles until they are internalized by DCs. We designed reduction-sensitive cationic dextran nanogels in which an antigen (ovalbumin, OVA) is reversibly immobilized to the hydrogel network via disulfide bonds. These bonds are stable in the extracellular environment but are cleaved in the cytosol of DCs due to the presence of glutathione resulting in triggered released of the loaded antigen after internalization of the nanogels by DCs. These nanogel OVA conjugates showed intracellular release of the antigen when the nanogels were internalized by DCs and boost the MHC class I antigen presentation. Besides that nanogels can be used for the intracellular delivery of tumor antigens, these nanoparticles can also be used for the cytosolic delivery of therapeutic proteins. Ribonuclease A (RNase A), as an anti-tumor therapeutic, has its target site (mRNA) inside the cell and has shown poor efficacy in preclinical models as well as in clinical trials due to its insufficient cellular internalization. To this end, anionic dextran nanogels were prepared by an inverse mini emulsion technique followed by post loading at neutral pH of positively charged RNase A. To stabilize the electrostatically loaded protein in the nanogels, Traut’s modified RNase A was immobilized covalently in the nanogel network via disulfide bonds that can be cleaved in the reductive cytosolic environment. To enhance the cellular uptake of these anionic nanoparticles, the particle surface charge was reversed by noncovalent attachment of polyethylenimine (PEI). Glutathione triggered release of covalently conjugated RNase A was demonstrated. PEI coating of anionic nanoparticles facilitated their cellular uptake by MDA-MB 231 breast cancer cells. Importantly, PEI coated RNase A loaded nanogels exhibited a concentration-dependent cytotoxic effect by apoptosis after 24 h incubation with cancer cells, whereas the free protein and non-loaded nanogels at equal dose did not show any cytotoxicity. In conclusion, nanogels are attractive vehicles for the intracellular delivery of therapeutic proteins.

REFERENCES
Biomaterials are no longer considered innate structures and using functionalisation and biofabrication strategies to modulate a desired response whether it is a host or implant is currently an important focus in current research paradigms. Fundamentally, a thorough understanding the host response will enable us to design proper functionalisation and biofabrication strategies. The input from the host response needs to be weighed in depending on the host disease condition. In addition, biomaterials themselves provide immense therapeutic benefits which needs to be accounted in the design paradigm. Using functionalisation strategies such as enzymatic and hyperbranched linking systems, we have been able to link biomolecules to different structural moieties. The programmed assembly of biomolecules into higher-order self-organized systems is central to innumerable biological processes and development of the next generation of biofabricated scaffolds. Recent design efforts have utilized a developmental biology approach toward both understanding and engineering supramolecular protein assemblies. Structural moieties have taken a variety of different forms such as nanofibers and nanoparticulate. This approach has resulted in functionalisation of micro and nanoparticles with biomolecules that include designed peptide motifs, growth factors and a multitude of gene vector systems. In addition, nature itself has abundant structural complexity that can be biofabricated for harnessing in key targeted clinical applications.

Department of Chemical and Materials Engineering, National Central University, Jhongli, Taiwan & Nano Medical Engineering Laboratory, Riken Center for Pioneering Research, Wako, Japan

Stem cells are attractive sources in regenerative medicine. Human pluripotent stem cells (hPSCs), such as embryonic stem cells (hESCs) or induced pluripotent stem cells (hiPSCs), are one of the promising cell source to be used in the future. Therefore, developing appropriate biomaterials for stem cell culture is necessary. In this study, we targeted on three aspects in order to develop an optimal hiPSCs and cultivation method for its applications: (1) Xeno-free extraction and cultivation of human mesenchymal stem cells (hMSCs) from tissue samples as reprogramming cell sources. (2) A safer reprogramming method (Sendai virus vector) was applied to host cells for reprogra mming into hiPSCs. (3) Xeno-free conditions for hiPSCs cultivation on biomaterials. We applied PVA-IA hydrogel, poly (vinyl alcohol-co-vinyl acetate-co-itaconic acid), and immobilized extracellular matrices (ECMs) or ECM-derived nanosegments for specific cell cultivation. In PVA-IA-oligopeptide immobilized dish, we can provide both physical and biological properties on the surface by adjusting hydrogel stiffness from 10 to 30 kPa and grafting specific oligopeptides on it. Our results showed high stability of reprogrammed cells grew under PVA-IA grafted substrates having optimal elasticity. PVA-IA grafted substrates performed the highest reprogramming efficiency (0.03-0.21%). Furthermore, hiPSCs were induced to differentiate into cardiomyocyte on the biomaterials. We discuss which biomaterials and nanosegments are preferable to induce differentiation of hiPSCs into cardiomyocytes.
Prospects of tissue engineering in wound management

A. Piaggesi

The European Wound Management Association [EWMA (www.ewma.org)], is a multi-professional umbrella organization which comprehends more than 30 national organization throughout Europe, whose aim is to improve the quality of care for patients affected by chronic and acute wounds. EWMA was founded in 1991 by a group of wound care specialists who believed that focusing on wound management both from scientific, clinical and social point of view would be beneficial for the many patients affected by the various pathologies which are responsible of wounds in Europe. Since then EWMA has continuously worked to sustain and promote the research in wound management, to implement the education of health care professionals in this field, and to advocate for patients' rights and lives, both at European and global level. EWMA has international partnerships worldwide with other society in America, Asia, Africa and Australia, thus covering the whole world for wound care. EWMA developed and maintains a strong and transparent relationship with the most important companies in the field of wound management and one of its recognized roles is to connect the latest research with the potential utilizers, both companies and patients' organizations, both creating occasion of visibility for the researchers, who are encouraged to present their work at the annual scientific meeting of the association, and by publishing the EWMA Journal, which is the official paper of the association, on which the contributions of the scientists and clinicians are welcome. EWMA periodically produces position documents on various aspects of wound management, with a special interest in all the new technologies and strategies for wound management, and recently a document on advanced therapies has been released. The interest of EWMA for basic and translational sciences has been increased in recent years, and a closer relationship with the world of scientists interested in wounds and wound-related issues has been actively searched, in order to secure a most profitable and productive channel for the augmentation and amelioration of the diagnostic and therapeutic options for our patients. The participation of EWMA at TERMIS should be considered as the first bridge that has been set between the basic and translational science and the clinical fields in wound management, where EWMA proposes itself as the place to be for the year to come anyone interested in both aspects.

Engineering cell niches for TERM applications exploiting peptide self-assembly
A. Saiani
Presenting Author: Alberto Saiani, a.saiani@manchester.ac.uk
School of Materials and Manchester Institute of Biotechnology, The University of Manchester, M13 9PL Oxford Road, Manchester, UK

The use of non-covalent self-assembly to construct materials has become a prominent strategy in biomaterials science offering practical routes for the construction of increasingly functional materials for a variety of applications ranging from tissue engineering to in-vivo cell and drug delivery.\(^1\)\(^-\)\(^2\) A variety of molecular building blocks can be used for this purpose, one such block that has attracted considerable attention in the last 20 years is de-novo designed peptides.\(^3\)\(^-\)\(^4\) Peptides offer a number of advantages to the biomaterial scientists. The library of 20 natural amino acids offers the ability to play with the intrinsic properties of the peptide such as structure, hydrophobicity, charge and functionality allowing the design of a wide range of materials. Synthetic peptides are chemically fully defined and being build form natural amino acids they result usually in low toxicity and low immune response when used in-vivo. Our group has focussed on the development of a technological platform for the design of novel bio-functional materials exploiting the self-assembly of β-sheet forming peptides.\(^5\)\(^-\)\(^9\) The β-sheet motif is of increasing interest as short peptides can be designed to form β-sheet rich fibres that entangle and consequently form stable hydrogels. These hydrogels can be easily functionalised using specific biological signals and or drugs. Through the fundamental understanding of the self-assembly and gelation of these peptides \(^5\)\(^-\)\(^9\) we have been able to design hydrogels with tailored properties for a range of applications including cell culture\(^6\)\(^-\)\(^1\(^7\), tissue engineering\(^1\(^2\)\(^-\)\(^1\(^7\), cell and drug delivery and 3D-bioprinting. Here I will present our group’s journey from molecular self-assembly to bio-functional biomaterials and their commercialisation and the challenges encountered along the way.

High definition bioprinting – An enabling technology for TERM
A. Ovsianikov
Presenting Author: Aleksandr Ovsianikov, Aleksandr.Ovsianikov@tuwien.ac.at
Additive Manufacturing Technologies Group (https://amt.tuwien.ac.at), Institute of Materials Science and Technology, TU Wien, Vienna, Austria, Austrian Cluster for Tissue Regeneration (www.tissue-regeneration.at)

3D bioprinting and biofabrication are already providing disruptive solutions for tissue engineering and regenerative medicine (TERM). However, the most widespread technologies are based on computer-controlled deposition of cells or assembly of cellular units, and thus cannot achieve spatial resolution better than few tens of micrometres. Lithography-based methods approach the problem from a different direction, by producing 3D structures within cell-containing materials and can therefore overcome this limitation. Among these methods, multiphoton lithography (MPL) is an outstanding one as it can produce features even smaller than a single mammalian cell (down to around 100 nm). Our recent breakthroughs on the material development side enabled the use of MPL for direct fabrication of cell-containing constructs, giving rise to High-Definition Bioprinting. HD Bioprinting is able to recreate fine tissue structure with an unprecedented accuracy using biomimetic hydrogels closely resembling extra-cellular matrix (ECM). The further development of HD Bioprinting will facilitate the realization of elegant biological experiments, helping to elucidate biomimetic aspects of cell interaction with the surrounding environment. Our results demonstrate a wide range of exciting applications, from controlling morphology of stems cells in 3D to modelling barrier tissues in vitro and patterning of hierarchical vascular networks using co-culture of endothelial and stem cells. In this contribution the principles of HD Bioprinting, its recent progress of as well as its perspectives for further TERM applications, will be discussed. The presentation is supported by numerous examples.
Bone marrow niche and blood cell formation
A. Balduini 1,2
Presenting Author: Alessandra Balduini, alessandra.balduini@unipv.it
1Department of Molecular Medicine, University of Pavia, Pavia, Italy 2Department of Biomedical Engineering, Tufts University, Medford, MA, USA

Bone marrow failure is the result of diseases, trauma, or cancer treatments, leading to a decreased production of blood cells and consequently, the necessity of blood transfusions. A number of studies point to the bone marrow niche as the core of blood cell production but with many interesting complex environmental factors for consideration. Thus, future advancement in the study of blood cell production will depend on the evolution of bioengineering techniques for reproducing physiologically relevant conditions in the bone marrow niche environment. To achieve this goal, the field is moving towards the reproduction of the characteristic features of the physiologic bone marrow microenvironment ex vivo by the use of relevant biomaterials and bioreactors, along with appropriate human cell sources. These models are expected to provide better mechanistic understanding and control of blood component production as well as insight towards the development of systems for the generation of functional blood cells necessary in transfusion and regenerative medicine to replace blood-donor supply. We have successfully developed different bioreactor systems, using silk fibroin, mimicking the bone marrow environment and thereby supporting haematopoiesis and megakaryopoiesis to generate significant numbers of human platelets ex vivo [1-2]. Silk fibroin, derived from Bombyx mori silkworm cocoons, is a promising biomaterial for bone marrow tissue engineering because of its tunable architecture and mechanical properties, the capacity of incorporating labile compounds without loss of bioactivity and demonstrated ability to support platelet production without premature activation. Herein, our experience with bone marrow niche structure and composition, in combination with ex vivo models, in physiological and pathological conditions, will be discussed.

ACKNOWLEDGEMENTS: Cariplo Foundation (2013-0717), US National Institutes of Health (R01 EB016041-02), H2020-FETOPEN-1-2016-2017-SilkFUSION.

Prospects of tissue engineering in wound management
A.P. Marques1,2,3
Presenting Author: Alexandra P. Marques, apmarques@i3bs.uminho.pt
13B’s Research Group – Biomaterials, Biodegradables and Biomimetics, Headquarters of the European Institute of Excellence on Tissue Engineering and Regenerative Medicine, University of Minho, Avepark 4805-017 Barco, Guimarães, Portugal 2ICVS/3B’s – PT Government Associate Laboratory, Braga/Guimarães, Portugal 3The Discoveries Centre for Regenerative and Precision Medicine, Headquarters at University of Minho, Avepark 4805-017 Barco, Guimarães, Portugal

Tissue Engineering is currently one of the most promising areas of research aiming developing substitutes to restore, maintain or improve the function of a specific tissue. While the first tissue engineering product was a skin substitute, Apligraf®, and skin wound care has the longest history of clinical application and the highest record of marketing, current options proved to be replacement strategies rather than promoting tissue regeneration. In the case of chronic wounds, delayed healing is also associated to a very high recurrence rate to which current wound management approaches are not sufficiently effective to respond to. Healed tissue of higher quality, which is the outcome of an adequate healing progression and is critical to reduce wound recurrence rate, is therefore the outcome to pursue. Tissue engineering will certainly play a key role in targeting this issue by developing skin substitutes with improved functionality capable of directing the healing mechanisms into the regenerative pathway. On the other side, tissue engineering also allows, by taking advantage of the tailoring of biomaterial features, to advance wound dressings. Both perspectives require the need to better understand the pathophysiology of each wound as well its progression under specific conditions to be able to control their therapeutic action. Gene therapy or gene editing approaches are examples of how a better knowledge of the healing factors or of a skin disease is a demand for a successful outcome. However, as one solution does not fit all wounds, future therapies must be adapted to the healing stages. For example new methods have been employed to create innovative 3D matrices with intrinsic features capable of respond in situ to micro-environmental wound stimuli. In these cases, the temporal changes can determine the release, at a specific time point, of a mediator that was missing for the adequate progression of the healing. Interestingly, this is also in line with 4D printing, an emergent area of the field of tissue engineering that integrates time as the fourth dimension. In fact, in addition to a requirement for an automated process, the complexity of skin tissue and consequently of its healing, is one of the reasons for the use of 3D printing technologies to develop improved and more realistic tissue engineered skin grafts. In conclusion, being a multidisciplinary area in which different expertise stakeholder actively collaborate, tissue engineering reunites the ideal setting to improve wound healing therapies holding therefore great prospects for this area.

Engineering the stem cell niche – Translation to the clinic
A. El Haj
Presenting Author: Alicia El Haj, a.elhaj@bham.ac.uk
Healthcare Technology Institute, Institute of Translational Medicine University of Birmingham UK

Engineering complex tissues creates major challenges for tissue engineering and regenerative medicine strategies. Complex form and function in tissues comprise multiple musculoskeletal tissues with cross-tissue integration and junctions. Our lab has been involved in understanding the ways we can engineer a stem cell niche which can go on to regenerate tissues. Our aim is to deliver donor progenitor cells which can build and define replacement tissues in vivo. The challenge lies in engineering control solutions for stem cells which can re-engineer the surrounding environment in dynamic and static conditions with clinical relevance. We have developed multiple control systems which can be aligned with cell based therapies and are currently translating these approaches towards first in man. Using experimental and theoretical modelling, we have designed tissue models which allow us to test control strategies in vitro. New strategies for labelling and defining tissue turnover and dynamics have been designed which can be used for validating our tissue models and defining success. In this presentation, I will describe the development of our novel stem cell bandage which can be used for directing and maintaining stem cell communities in bone and cartilage. I will present our work in nanomedicine with remote magnetic particle control strategies for stem cell activation and optimised differentiation which is now in preclinical trial. Finally, I will align these strategies to potential treatments for conditions such as in Orthopaedics and Craniofacial repair. Our aim is to translate these approaches towards a clinical solution for patients.

Self-assembling peptide hydrogels for 3D cell culture; From molecular self-assembly to commercial product
A.F. Miller¹,²
Presenting Author: Aline F. Miller, a.miller@manchesterbiogel.com
¹Manchester BIOGEL, 19F4 Mereside, Alderley Park, Alderley Edge, Cheshire, SK10 4TG, United Kingdom ²School of Chemical Engineering and Analytical Science, Manchester Institute of Biotechnology, 131 Princess Street, University of Manchester, Manchester, M1 6NF, United Kingdom

Over the past two decades, significant effort has been made to develop soft materials, i.e.: hydrogels, for the design of 3D cell niches. Taking inspiration from the many millennia proteins have had to perfect their structure-property-function relationships, self-assembling peptides have emerged as a class of promising material building blocks as has they allow the design of very stable, highly versatile hydrogels for use in a variety of biomedical applications (see Figure 1). We have developed a platform for the design of hydrogels exploiting the self-assembly of short (8-9 amino acids) β-sheet forming peptides, and the design is based on the alternation of hydrophilic and hydrophobic residues. The properties of these materials (e.g.: functional and mechanical) can easily be tailored to accommodate different cells’ needs. We have used these novel materials for the culture of a variety of cells including: chondrocytes, osteoblasts, nucleus pulposus as well as mesenchymal stem cells. By varying the properties of the hydrogels (e.g.: stiffness, charge) we were able to design 3D niches capable of directing cell behaviour. We are currently using these novel materials in a variety of tissue engineering and regenerative medicine applications (e.g. cardiac regeneration, Barrett’s oesophagus disease). Moreover we are using the scaffolds to build 3D vascularized tumour models and physiologically relevant gut models. Our results clearly demonstrate that our materials offer great promise for the design of specific 3D cell niches due to their low immunogenicity, high biocompatibility and the ability we have to control and tailor their properties. We are currently commercializing a range of these materials to offer researchers and clinicians an easy to use and ready to use matrix for 3D cell culture, 3D bioprinting and drug delivery applications. These materials are fully synthetic and have no batch to batch variation hence can be clinically translated.

Transforming proteins into functional biomaterials for complex tissue engineering
A. Mata\textsuperscript{1}
Presenting Author: Alvaro Mata, a.mata@qmul.ac.uk
\textsuperscript{1}School of Engineering & Materials Science, Queen Mary University of London, London, UK

There is great interest to develop new materials with properties that resemble those of biological systems such as hierarchical organization, the capacity to grow or self-heal, and the ability to guide complex biological processes. These kinds of materials would open opportunities to engineer tissues with a much-needed higher level of complexity and functionality. To this end, supramolecular chemistry offers an exciting opportunity to grow such materials from the bottom-up using molecules and processes found in nature. However, the ability to transform molecular and nano-scale design into functional devices with practical utility at the macroscale remains a challenge. The talk will describe new strategies that integrate supramolecular chemistry with engineering principles to develop practical materials with tuneable and advanced properties such as hierarchical organization, the capacity to grow, tuneable mechanical properties, and specific bioactivity \cite{1-3}. These materials are being used towards new regenerative therapies of tissues such as enamel, bone, and blood vessels as well as more biologically relevant in vitro models for applications such as cancer and neurological disorders.

Dual alginate crosslinking and two degradation modes for local patterning of biophysical and biochemical properties
A. Cipitria

Presenting Author: Amaia Cipitria, amaia.cipitria@mpikg.mpg.de

1Max Planck Institute of Colloids and Interfaces, Department of Biomaterials, Potsdam, Germany

Native microenvironments are dynamic and exhibit biophysical and biochemical cues orchestrated in space and time. Biomaterials with tunable mechanical and degradation properties, and spatial control of polymer-bound biomolecules can be used to mimic the dynamic cellular microenvironment that cells are exposed to and thereby recapitulate the reciprocal interplay between the cells and extracellular matrix. We have developed an alginate-based material system that relies on two crosslinking types and degradation modes: (i) spontaneous Diels-Alder click chemistry of norbornene and tetrazine functional groups, with the potential to impart passive, hydrolytic degradation via oxidation [1] and (ii) UV-initiated thiol-ene click chemistry with the potential to impart enzymatic degradation via incorporation of MMP-sensitive peptide crosslinkers. Enzymatically degradable alginate hydrogels were fabricated by combining norbornene-modified polymer and MMP-sensitive peptides. The degree of crosslinking and stiffness were controlled by the polymer molecular weight and crosslinker concentration. The degradation kinetics were characterized by changes in wet weight upon incubation in collagenase. Mouse embryonic fibroblasts were encapsulated into degradable and non-degradable controls and cell viability and morphology were tracked over 14 days. Cell viability remained high for all conditions, spread morphology was observed in degradable gels with a significant difference in the cell longest axis, while cells remained round in non-degradable gels. Ongoing work includes tracking of in-vivo degradation upon subcutaneous implantation in mice via fluorescence imaging and ex-vivo characterization of cell and tissue infiltration. Diels-Alder and thiol-ene click crosslinking were combined orthogonally for dual crosslinked materials. Patterns in stiffness were generated by spatially controlling the location of UV-mediated thiol-ene crosslinking via photomasks with stripes of 500 um thickness, and confirmed by micro-indentation surface mapping. Fibroblasts seeded on these materials exhibited a different morphology, with spread cells aligned along the channel axis on stiff regions, and round cells on soft regions. Patterns in biomolecules for cell attachment were achieved by first crosslinking the gel with Diels-Alder chemistry and then coupling a thiol-RGD peptide on regions exposed to UV through photomasks. Ongoing work explores the effect of 3D patterned hydrogels and polymer-bound bone morphogenetic protein-2 and peptide mimetics to guide the osteogenic differentiation of primary human mesenchymal stem cells. This biomaterial-based strategy allowing spatial patterning of biophysical and biochemical cues could direct cell behavior and support guided tissue regeneration.

Bioengineering materials for orthopedic regenerative medicine
A.M. Ferreira Duarte
Presenting author: Ana M. Ferreira Duarte, ana.ferreira-duarte@ncl.ac.uk
School of Engineering, Newcastle University, Newcastle-Upon-Tyne, UK

Although only few cell therapies are currently available in clinics that allow the regeneration of a damaged tissue, cell therapies have the potential to treat a broad range of diseases and change the way on how medicine is practiced. Among the main challenges that limit the widespread clinical use of cell therapies in orthopaedics are the maintenance of cell functions, reproducible cell expansion for transplantation, protection and control of cells condition pre- and post- transplantation in patients. Biomaterials offer the possibility to tune the bio-chemical and mechanical properties to overcome these difficulties by facilitating transplanted cell survival, therefore speeding-up the drug discovery and screening to treat diseases, and accelerate the clinical application of cell-based therapies. Synthetic and natural polymers are often used to recruit specific cells to support or guide their function for therapy. Moreover, biomaterials can be modified to regulate specific cellular functions such as migration, attachment, proliferation and differentiation by incorporating mechanical and/or chemical cues. The combination of advanced biomaterials and bio-fabrication technologies (e.g. bioprinting) can facilitate the control and reliability of cell manipulation procedures and protocols for developing and scaling up effective therapies. In our recent works, we demonstrated the importance of cell density in the development of bone microtissues derived from human bone marrow stem cells and its effect in the tissue maturation rates, as a result of bioprinting high cell densities (e.g. 40 million cells/ml) in low-viscosity and natural-based bioinks. Herein, the combination of materials and use of advanced additive manufacturing technologies for the development of orthopaedic cell therapies will be discussed.
Novel biodegradable dendritic block copolymers as nucleic acid vectors to the central nervous system
A.P. Pêgo
Presenting author: Ana P. Pêgo, apego@ineb.up.pt
INEB – Instituto de Engenharia Biomédica / i3S - Instituto de Investigação e Inovação em Saúde, Universidade do Porto, Rua Alfredo Allen, 208, 4200-135 Porto; Faculdade de Engenharia da Universidade do Porto (FEUP), Porto, Portugal; Instituto de Ciências Biomédicas Abel Salazar (ICBAS), Universidade do Porto, Porto, Portugal

Dendrimers are attractive carriers for several bioactives due to their unique structural features: globular, well-defined, very branched and controllable nanostructure, low polydispersity and multivalency. Among such bioactives nucleic acids (NAs) are readily compacted into nanostructures named “dendriplexes”, when complexed with positively charged dendrimers that are able to protect them from enzymatic degradation and rapid renal clearance after i.v. administration. However, one important disadvantage of the most commonly used dendrimers is their non-degradability under physiological conditions, that can lead to toxicity by bioaccumulation. Moreover, in the gene therapy field, vector stability can further hinder the intracellular release of the NA, consequently leading to low transfection efficiencies (TE). Therefore, recent interest has focused on the development of biodegradable dendrimers, but only few works report their biomedical applications. Here, we present a new family of fully biodegradable and biocompatible PEG-dendritic block copolymers, as well as their function as nucleic acid vectors. Interestingly, the fully degradable character was crucial for a better nucleic acid release from the dendriplexes, contributing to an amazing improvement of the TE compared to their hybrid biodegradable counterparts. The ultimate application we are seeking for the proposed dendrimer-based vectors is the nucleic acid delivery to neuronal cells in the brain. Consequently, neuronal targeting is being explored.
Therapeutic vascularization of skeletal muscle
A. Banfi$^{1,2}$

Therapeutic angiogenesis in skeletal muscle, i.e. the generation of new vessels by delivery of specific factors, is required both for rapid vascularization of engineered grafts and to treat ischemic conditions. In particular, muscle tissue presents some specific features, like a high density of capillary networks and a paucity of extracellular matrix between myofibers, which require consideration when promoting muscle angiogenesis. Vascular Endothelial Growth Factor (VEGF) is the master regulator of angiogenesis. However, uncontrolled expression leads to vascular tumors (angiomas). Major challenges to fully exploit VEGF potency for therapy include the need to precisely control the in vivo distribution of growth factor dose and its duration of expression. We previously found that the therapeutic window of VEGF delivery depends on the VEGF amount in the microenvironment around each producing cell rather than on the total dose, since VEGF remains tightly bound to extracellular matrix and a few "hotspots" of high expression are sufficient to cause angioma growth even if the total dose is rather low. On the other hand, short-term expression of less than about 4 weeks leads to unstable vessels, which promptly regress following cessation of the angiogenic stimulus. Here I will present recent work aimed at: 1) translating fundamental principles of VEGF function into clinically applicable approaches to induce controlled angiogenesis, through the use of recombinant factors-decorated fibrin matrices [1]; and 2) investigating the mechanisms that regulate vascular stabilization and the switch between normal and aberrant angiogenesis in skeletal muscle in vivo, to identify novel molecular targets to improve both the safety and efficacy of VEGF [2-3].

Response of mesenchymal stem cells to flow in the Nichoid 3D microstructured substrate
A. Remuzzi

Presenting Author: Andrea Remuzzi, andrea.remuzzi@unibg.it

1Department of Management, Information and Production Engineering, University of Bergamo

INTRODUCTION: The communication between stem cells and the microenvironment affects cell fate and behavior. Physical and mechanical factors have a crucial role in triggering mesenchymal stem cells (MSCs) response. Here, we assess the effect of flow exposure on MSCs cultured in 2D conditions and in the Nichoid nano-engineered 3D substrate [1].

METHODS: We designed and constructed a perfusion chamber and a closed circuit. Rat bone marrow MSCs were seeded on 2D or 3D culture supports. Substrates were then maintained in static conditions or exposed to a wall shear stress of 3 dyn/cm². Morphological analysis, SEM analysis, and immunocytochemistry (ICC) were performed at 48 hours.

RESULTS & DISCUSSION: After flow exposure 2D-cultured cells displayed a more elongated morphology, while Nichoid-cultured cells were strongly anchored to the 3D structure. ICC showed that MSCs cultured in cell monolayer have large and flattened cytoplasm and nuclei, while on the Nichoid they have long actin filaments and small but spherical nuclei. Dynamic conditions induced F-actin fibers thickening on both substrates. The 3D Nichoid substrate, as well as flow exposure, induced a different intracellular localization of the mechanotransducer YAP, consisting in an increased cytoplasmic retention of this transcriptional co-activator, confirming that mechanical cues deriving from cell anchorage to the structure and from shear stress are able to influence stem cell response.

CONCLUSIONS: Our versatile and optically accessible system can be used to reproduce physiological flow conditions, able to influence cell response, both on 2D and 3D culture substrates.

Figure 1: (A) Cytoskeletal organization of MSCs on 2D or 3D substrates in static or dynamic culture. (B) 3D culture conditions and flow exposure induced a decrease in YAP nuclear localization.

On the convergence of the sciences and why veterinary science can take center stage in tissue engineering innovation

A. Kaasi¹,²

Presenting Author: Andreas Kaasi, ak@evascientific.com

¹Eva Scientific Ltd., São Paulo, SP, Brazil ²Santa Casa de São Paulo, Institute for Research, Technology Innovation and Education, São Paulo, SP, Brazil

Veterinary science is embedded, though often inconspicuously, into many of the other sciences and facets of human culture. The involvement may take place in different phases of each specialty, ranging from research, development, production, sales and marketing and support, here connoting the versatility of veterinary science in the different stages of the traditional innovation life cycle. As an example of an involvement in research and development, the one most familiar to us engaged in Tissue Engineering and Regenerative Medicine (TERM), veterinarians run vivariums for biological and medical R&D. In production, vets are required by law to be involved in the safety and efficacy of tissues such as meat and dairy from normal animals for human consumption, and also of tissues from intentionally modified animals, such as transgenic animals seeking an increased yield or enhanced properties, such as humanized cow milk [1]. As for the sales, marketing and support activities, vets play a role in the commerce, beautification (grooming) and training (sports) of small and large animals. Multidisciplinarity is, thus, a central trait of veterinary science and of the individual vet, yet their potential of interdisciplinarity has perhaps not been exploited optimally. Tissue engineering, a branch of science that is both multidisciplinary and interdisciplinary at the same time, would benefit greatly of a more intimate involvement of veterinary scientists and clinicians. Speaking from a personal perspective, our work with decellularized tissues such as heart valves [2], or decellularized whole organs, such as the kidney or pancreas [3], insights of veterinary anatomy nature that the aortic valve right coronary cusp is muscular[4], that the kidney is similar albeit with some differences [5] and the pancreas vastly different [6], aid in the process of engineering these tissues and organs. The concepts of “One Medicine” [7], and “One Health”[8] have both been around for centuries, forming useful links between veterinary and human medicine and health, respectively. The more recent shift from a pure medical (diagnosis, treatment and prevention of disease in humans and animals) to a health (well-being in humans and animals) focused collaborative initiative, signals a direction of increasingly transdisciplinary and holistic approaches. The next shift involves the impact of tissue engineering methods on the health or state of animals, the impact this has on the tissues and organs of these animals which we, humans, consume for food, and the impact this has on our psychology and culture. Besides these examples, this talk will explore additional situations or opportunities wherein veterinary professionals already are or would be indispensable for TERM.

SPARC-mediated mechanotransduction in tendon homeostasis and tissue interface maturation
A. Traweger
Presenting author: A. Traweger, andreas.traweger@pmu.ac.at
Paracelsus Medical University, Institute of Tendon and Bone Regeneration, Spinal Cord Injury &
Tissue Regeneration Center Salzburg, Austria

Tendons and tendon interfaces display a poor regenerative capacity and injuries remain clinically
challenging. Tendons sense mechanical load, however our knowledge on how external loading affects
tendon homeostasis and degeneration remains fragmentary. Here we provide evidence that the
matricellular protein SPARC is critically involved in the mechanobiology of tendons and is required
for homeostasis and tissue interface development. We show that loading tendons at the early postnatal
stage resulted in tissue hypotrophy and the fibrocartilaginous transition zone at the Achilles tendon
enthesis was impaired in mice lacking SPARC. Further, tendon insertion length at the myotendinous
junction was significantly shorter and was characterized by fatty infiltrations. In vivo, treadmill
training led to a higher prevalence of spontaneous tendon ruptures and a net catabolic adaptation in
SPARC-/- mice. Interestingly, tendon hypoplasia was attenuated in SPARC-/- mice in response to
muscle unloading with botulinum toxin A injection. In vitro culture of tendon organoids showed that,
while the constructs from both WT and SPARC-/- mice responded to uniaxial loading by increased
AKT phosphorylation, the downstream activation of S6K was only impaired in organoids derived
from SPARC-/- mice, resulting in the reduction of type I collagen synthesis. To underscore the
clinical relevance of our findings, we have further revealed that a novel missense mutation in SPARC
is associated with a full-thickness tear of the rotator cuff in patients. Together we provide evidence
that SPARC is an essential matrix protein necessary for mechanotransduction in load-induced tendon
and tissue interface maintenance.
Seeing is believing: Application of radiopaque biomedical polymers in interventional medicine
A. L. Lewis

X-Ray Radiopacity: A growing number of therapeutic procedures are being conducted using minimally-invasive approaches, usually under the guidance of some type of imaging modality in order to navigate the therapy to the target site, and in some cases to subsequently assess the effectiveness of the treatment. X-ray based imaging techniques such as fluoroscopy and computed tomography (CT) are commonly employed for real time intra- and post-procedural imaging. Certain materials, such as most metals, can absorb the X-ray energy (a property known as radiodensity or radiopacity) and can therefore be clearly seen using X-ray imaging, whereas conventional biomedical polymers are generally radiolucent and must be modified in order to render them specifically radiopaque. Radiopaque Embolisation Devices: Embolisation devices are used to divert blood flow or completely occlude the lumen of vessels for a variety of purposes, including prevention of internal bleeding, treatment of organ dysfunction or blocking of vessels that feed benign or malignant tumours. The devices can range from metallic coils to particulate and liquid-based systems usually composed of polymeric materials. Liquid systems are normally mixed with radiopaque components at the point of use to introduce radiopacity, whilst particulate embolics have been traditionally radiolucent. Recently there have been significant advances in facile chemical routes to the introduction of radiopaque groups onto the polymer structures to confer inherent radiopacity [1]. We investigated many different methods for adding radiodense atoms such as iodine, barium, and bismuth into embolic particles, to create a Radiopaque Bead (ROB). Covalent attachment to the preformed beads using an aromatic iodinated species similar to that used as the basis of soluble contrast agents offered the best balance between radiopacity and ability to handle and deliver the ROB. Optimisation of iodine content was established in vitro by imaging assessment using a variety of X-ray based methods using ROB phantoms. In vitro analyses of mechanical properties, flow penetration, suspension times, microcatheter delivery and robustness and drug loading/elution were undertaken to fully characterise the device. ROB distribution, imaging and long-term biocompatibility was established with rabbit and sheep renal embolisation studies, a rabbit VX2 tumour model and a long-term swine hepatic artery embolisation study using micro-CT, fluoroscopy and CBCT and MDCT, prior to moving to First in Man clinical evaluation. The ability to see where the ROB are going is enabling the physician to more precisely target the area of treatment, identify areas of potential undertreatment and improve patient safety by detecting any off-target embolization – together with the benefits of the sustained localised release of chemotherapeutic agent.

Since the engraftment of the transplanted mesenchymal stem cells (MSCs) has been only partially documented, it is suggested that paracrine-mediated signals originating from MSCs must be implicated in tissue regeneration. It is possible that microvesicles (MVs) or soluble factors contained in conditioned medium secreted by MSCs, are mediators of cell-to-cell communications that ultimately lead to tissue repair [1]. It has been suggested that a large number of molecular mediators and MVs are involved in the early embryo-maternal interaction, too. Indeed, equine embryos at day 8 are thought to secrete MVs, which can modulate the functions of the oviductal epithelium through transferring early pregnancy factor and micro-RNAs [2]. From the maternal side, endometrium-derived MVs revealed to have potential targets in biological pathways highly relevant for embryo implantation [3]. In this context, infertility could occur as a malfunction of the endometrium-embryo ‘dialogue’ when the endometrial production of these mediators could be impaired by persistent endometritis. In view of restoring the fully functional embryo-maternal communications, and to treat endometritis that reduce conception rate and increase delivery-to-conception intervals in both bovine and equine species, regenerative medicine using cell free products from MSCs is proposed as a new approach. In addition, considering that MVs are involved in the regulation of gene decisive in biological processes such as gametogenesis, fertilization, implantation and embryo development, amniotic derived MVs are suggested during bovine in vitro embryo culture and cryopreservation to evaluate survival rate after cryopreservation and on pregnancy rate after embryo transfer of fresh or cryopreserved MV-exposed embryos. Basing on our data, these MVs up-regulate the expression of GPX1 gene and down-regulate the expression of BAX gene improving the survival rate following cryopreservation and the rate of pregnancy, probably for limited lipid peroxidation and apoptosis damages. Least but not last, to date the conditioned medium (CM) obtained from in vitro MSCs has been proven to be sufficient to stimulate the structural and functional regeneration of cardiac, renal, spinal cord, and tendon tissues [4] by a paracrine action due to the action of bioactive factors. In this perspective, we examined whether administration of CM generated from amniotic mesenchymal cells could be useful as mastitis therapy in cattle.

The extracellular matrix (ECM) is a dynamic scaffold full of biochemical, biomechanical and topographical signals that instruct cells in tissue homeostasis, healing and regeneration. Although tissue-derived ECM belongs to the most successful biomaterials in clinical application, these clinical products face many limitations. Besides immunogenicity, risk of disease transmission and shortage of donor organs, these also include a large material variability and a fixed composition thus bioactivity. This is the reason why we set-off to engineer extracellular matrices with customized bioactivities in vitro, which upon processing and implantation will guide regeneration processes. The utilization of the biophysical principle of macromolecular crowding (MMC) during in vitro ECM assembly hereby ensures relevant amounts of ECM to be deposited. As a result, these in vitro matrices exhibit a strong and stable bioactivity and can be tailored to be anti-inflammatory, pro-angiogenic and/or anti-fibrotic. Additionally, this in vitro ECM platform allows us to study and decipher the ECM’s mechanism of action. In particular, we were able to shed light on the role of hyaluronic acid in cell-guided fibronectin fibrillogenesis. This novel class of biomaterials based in vitro engineered ECM allows to utilize the whole complexity of signalling employed by the ECM, while being customized in its bioactivity.
Design and study of self-assembling peptides as scaffolds for tissue engineering
A. Mitraki
Presenting author: Anna Mitraki, mitraki@materials.uoc.gr
Department of Materials Science and Technology, University of Crete, Heraklion, Greece, and Institute of Electronic Structure and Laser (IESL) FORTH, Heraklion, Greece

Self-assembled peptides gain increasing interest as biocompatible and biodegradable scaffolds for tissue engineering. Rationally designed self-assembling building blocks that carry cell attachment motifs such as Arg-Gly-Asp (RGD) are especially attractive. We have been using a combination of theoretical and experimental approaches towards such rational designs. We have been especially focusing on modular designs that consist of a central ultrashort amphiphilic motif derived from the adenovirus fiber shaft. This central amphiphilic motif can be further modified with amino acids targeted for various functionalities. We have been studying peptides comprising this central motif, further combined with the RGD motif and cysteine residues that allow further functionalization possibilities, such as conjugation of growth factors or attachment to surfaces. The designer peptides self-assemble into fibrils that are structurally characterized with Transmission Electron Microscopy, Scanning Electron Microscopy and X-ray fiber diffraction. Furthermore, they support cell attachment and proliferation of model cell lines. We further extended this approach to computational design of bifunctional self-assembling peptides bearing calcium and strontium binding residues as well as the cell adhesive motif RGD. Such short self-assembling peptides that are amenable to computational design offer open-ended possibilities towards multifunctional tissue engineering scaffolds of the future.
Intervertebral disc: A journey from embryonic development to cell-based regenerative strategy
A. Camus1,2
Presenting Author: Anne Camus, anne.camus@univ-nantes.fr
1Inserm, UMR 1229, RMeS, Regenerative Medicine and Skeleton, Université de Nantes, ONIRIS, Nantes, F-44042, France 2Université de Nantes, UFR Odontologie, Nantes, F-44042, France

Low back pain is one of the most common musculoskeletal disorder and the most common causes of disability in industrialized countries. Although the aetiology of low back pain is unknown, it is often (40%) associated with degeneration of the intervertebral disc (IVD). There is currently no effective treatment for disc degeneration [1]. This is largely due to a lack of basic knowledge of the molecular and cellular controls of disc development, growth, differentiation, and homeostasis, during embryogenesis and at different stages of life. The nucleus pulposus (NP) is the highly hydrated central part of the IVD that plays a key role in spine kinematic and where degenerative changes are thought to initiate. Lineage tracing experiments in the mouse demonstrate that notochord cells (NTCs) are the precursor cells that give rise to the NP [2]. There is also considerable evidence that NTCs have a significant influence on the homeostasis of the IVD and their loss has been correlated with aging and degeneration in humans [3]. The generation of NTCs is therefore a promising approach to regenerate IVD. Our research aims to identify key molecules associated with cell fate decisions, morphogenesis and maturation of the NTCs required for disc formation that may also regulates the maintenance of the mature NTCs for functional and healthy adult disc tissue. A thorough knowledge in developmental biology is relevant to elucidate IVD repair in humans and also to the production of NTCs from pluripotent stem cells for regenerative strategies.

Do dental stem cells of the apical papilla have the teeth for spinal cord repair?
A. des Rieux

Presenting Author: Anne des Rieux, anne.desrieux@uclouvain.be

1Louvain Drug Research Institute, Advanced Drug Delivery and Biomaterials, Université catholique de Louvain, UCLouvain, Avenue Mounier, 73, B1 73.12, 1200 Brussels, Belgium

Spinal cord injury (SCI) is the major cause of long-term paralysis via traumatic event. Strategies for spinal cord repair after injury are extensively studied over the world. While cell-based therapy holds great hope for recovery after SCI, this area remains challenging for scientists and clinicians. Transplantation of different type of mesenchymal stem cells (MSC) has been investigated as potential therapies for SCI but, despite this advancement no definitive treatment exists and SCI continues to pose clinical and socio-economic problems. The aim of this work was to provide an innovative strategy for spinal cord repair based on a new MSC source: dental stem cells from apical papilla (SCAP). Dental stem cells (DSC) have been largely investigated in dental therapies, especially in regenerative endodontics. DSC hold a not yet exploited potential in regenerative medicine and are particularly becoming attractive for nervous system repair strategies thanks to their neural crest origin. Up to now, no one investigated SCAP potential for spinal cord repair so far. Stem cells from the apical papilla (SCAP) derive from the neural crest and express numerous neurogenic markers. The goal of the present work was to investigate their therapeutic potential regarding the treatment of SCI. We observed that implantation of a whole human apical papilla at the lesion site improved gait of spinally injured rats(1). We demonstrated that SCAP have immunomodulatory properties and can stimulate oligodendrocyte progenitor cell differentiation(2). And finally, we showed that implantation of the apical papilla exerted an anti-inflammatory and neuroprotector effect. This work underlines the potential therapeutic benefits of SCAP for spinal cord repair.

ACKNOWLEDGEMENTS: Anne des Rieux is a Research Associate at the FRS-FNRS (Fonds de la Recherche Scientifique). We are also grateful to Université Catholique de Louvain (FSR) and IRP for the financial support.

Modulating macrophages to drive in situ cardiovascular tissue engineering
A.I.P.M. Smits¹,²
Presenting Author: Anthal IPM Smits, a.i.p.m.smits@tue.nl
¹Soft Tissue Engineering and Mechanobiology (STEM) group, Department of Biomedical Engineering, Eindhoven University of Technology, Eindhoven, The Netherlands ²Institute for Complex Molecular Systems (ICMS), Eindhoven University of Technology, Eindhoven, The Netherlands

Materials-driven tissue regeneration using acellular, resorbable synthetic scaffolds is an attractive strategy to obtain living, adaptive cardiovascular replacement tissues, such as heart valves and blood vessels. Upon implantation, such scaffolds induce the recruitment and infiltration of endogenous cells, which degrade the temporary scaffold material and replace that with functional new tissue directly in situ. By omitting lengthy and costly in vitro culturing protocols, the use of such a relatively simple acellular synthetic device offers several intrinsic translational advantages, such as off-the-shelf availability and reduced costs. Various recent studies have demonstrated the proof-of-concept for in situ cardiovascular tissue engineering (TE) using resorbable synthetic scaffolds. One example is the development of a resorbable heart valve scaffold, which demonstrated sustained functionality for 12 months when implanted as pulmonary valve replacement in sheep [1]. Although the in situ TE approach has shown great potential, the in vivo regenerative processes are difficult to control and not well-understood. The host inflammatory response to the implanted scaffold is postulated to play a hinging role during in situ TE [2]. Macrophages specifically display diverse commanding functions in the processes of tissue formation and remodeling, by signaling to tissue-forming cells (e.g. myofibroblasts) -similar to wound healing-, as well as the degradation of the scaffold material. These dynamic cellular functions are dependent on the macrophage polarization state, which can be modulated via the scaffold design parameters (e.g. microstructure), as well as the local biochemical and biomechanical environment, the latter being particularly relevant in cardiovascular applications. In addition to material-dependent parameters, patient-specific, material-independent parameters, such as patient age, sex, and potential systemic comorbidities (e.g. diabetes) are likely to have a profound effect on the efficacy of in situ TE strategies due to their influence on the patient’s intrinsic inflammatory state and regenerative capacity [3]. Here, we will elaborate on the current mechanistic know-how of the in situ TE process, with a specific focus on cardiovascular applications (i.e. small-diameter blood vessels, heart valve replacements). Therein, the influence of scaffold design parameters, as well as scaffold-independent patient characteristics will be discussed in order to provide a prospective on the development of robust clinical treatments and the potential for personalized in situ cardiovascular TE strategies.

ACKNOWLEDGEMENTS: We gratefully acknowledge the financial support by the Ministry of Education, Culture and Science (Gravitation Program 024.003.013).

Tropoelastin and enhanced wound repair
A.S. Weiss
Presenting author: Anthony S. Weiss, anthony.weiss@sydney.edu.au
Charles Perkins Centre; School of Life and Environmental Sciences; Bosch Institute, University of Sydney, NSW, 2006, Australia

Tropoelastin is crosslinked as an essential step in the formation of elastin where it contributes to elasticity and biological interactions. An emerging model for tropoelastin is that it delivers this potency by emulating extracellular matrix interactions including those through development and repair. This paradigm for enhanced tissue repair encompasses a novel, pure, synthetic material that promotes the repair and fixation of soft tissues. The active component is tropoelastin and leverages its ability to promote new blood vessel formation and its cell recruiting properties to accelerate healing on applied tissues. Key to the technology is a stabilized form of human tropoelastin which allows for tuneable resorption. This implantable material is shaped at will where it hydrates to form a conformable protein hydrogel. Significant benefits in the extent of wound healing, dermal repair and regeneration of mature epithelium in preclinical animal studies are demonstrated superior to current methods of sterile bandaging, commercial hydrogel, and dermal regeneration. These developments will be discussed.
Stem cells hold great promise in the evolving field of regenerative medicine. Over the past two decades, different perinatal tissues have been shown to harbor a vast array of stem cells with therapeutic potential. Perinatal tissues are birth-related tissues and include the amniotic fluid and placenta-derived tissues such as the umbilical cord, the amniotic membrane, the chorion, and the maternal decidua. The cells isolated from perinatal tissues and the factors released from these cells are collectively referred to as perinatal derivatives (PnD). Research on the therapeutic applications of PnD is exponentially growing as documented by the 30-fold increase in scientific publications in the past 10 years, and the number of currently ongoing clinical trials. The multidisciplinary knowledge obtained by the main actors of the scientific, clinical, and industrial research has significantly advanced our understanding of PnD. There are however several issues that need to be addressed to ensure optimal research outcome and safe and efficient clinical applications. These issues range from the need to arrive to consensus on the nomenclature and optimal techniques for cell isolation, characterization, and to more advanced issues such as collating data toward an understanding of the mechanisms of action and therapeutic actions of perinatal derivatives. In 2018 the COST Action entitled “International Network for Translating Research on Perinatal Derivatives into Therapeutic Approaches-SPRINT” was approved. The aim of this Action is to unite a currently fragment critical mass to enhance both the basic understanding and translational potential of perinatal derivatives. This network has an interdisciplinary plan of action which will address open questions (e.g. consensual terms for classification, comparison, standardized operative procedures for harvesting, processing, cryopreservation), monitor and build upon ongoing studies (e.g. from comparison of preclinical studies and identification of mechanisms of action, up to the translation into European clinical practice by addressing regulatory issues and stakeholders’ view), and thus ultimately promote more efficient, safer, and faster advancement of their therapeutic applications and attract industrial investments.

ACKNOWLEDGEMENTS: This abstract is based upon work from COST Action SPRINT, supported by COST (European Cooperation in Science and Technology). Stem cell secretome as a modulator of CNS regeneration

A.J. Salgado\textsuperscript{1,2}

Presenting Author: António J. Salgado, asalgado@med.uminho.pt

\textsuperscript{1}Life and Health Sciences Research Institute (ICVS), School of Medicine, University of Minho, Braga, Portugal \textsuperscript{2}ICVS/3B’s, PT Government Associate Laboratory, Braga/Guimarães, Portugal

The low regeneration potential of the central nervous system (CNS) represents a challenge for the development of new therapeutic strategies. Mesenchymal stem cells (MSCs) have been proposed as a possible therapeutic tool for CNS disorders, namely due to the beneficial actions of their secretome. Indeed, the latter possesses a broad range of neuroregulatory factors that promote an increase in neurogenesis, inhibition of apoptosis/glial scar, immunomodulation, angiogenesis, neuronal and glial cell survival, as well as relevant neuroprotective actions into different pathophysiological contexts. Considering their protective action in lesioned sites, MSCs, and their secretome, might also improve the integration of local progenitor cells in neuroregeneration processes. In this sense their use could represent an important vehicle for the establishment of future CNS regenerative therapies. In the present talk the role of MSCs secretome, on phenomena such as in vitro and in vivo neuronal/glial survival, as well as its characterization will be addressed. Moreover its use as a therapeutic agent for injury and neuro-degeneration of the CNS, namely Spinal Cord Injury and Parkinson’s, Diseases and Spinal Cord Injury regenerative medicine will also be presented and discussed. Finally, new trends on how to modulate the secretome MSCs will also be presented.

In the field of tissue engineering and regenerative medicine, there is more demand for biomaterials that are able to provide optimal surface for cell culture and growth, environment for cell expansion and manufacturing, local delivery to enhance new tissue formation. However, for these biomaterials to be transferred from research laboratory toward practical applications where minimal chemical manipulation is required, new simple and efficient synthetic and fabrication tools are required. For examples, synthetic polymers are used as delivery systems need to contain biomimetic adhesion sites for the facile conjugation of bioactive agents. Currently, research towards the synthesis of these types of delivery systems has been met with the challenge of choosing between natural polymers abundant with biologically active interaction sites or mechanically superior synthetic polymers lacking in useful functional groups. Synthetic polymers have advantageous chemical properties, such as defined structure and composition, the versatility of functional groups and synthetic routes, ability to tailor and tune degradation rate and mechanical strength, however, they suffer from poor surface adhesion and an inability to easily conjugate biomolecules such as proteins or peptides that can interact with cellular components. For decades, polyester polymers such poly(lactic-co-glycolic acid) (PLGA), Poly(caprolactone) (PCL) and poly(lactic acid) (PLA) have been the preferred materials for delivery systems. However, these polymers are inherently difficult to work with. They lack functional groups needed to allow for easy conjugation to or control the adhesion of, bioactive agents. This, in turn, has limited their application. Post-functionalisation of these polymers, in which functional groups are substituted or modified using additional reagents, has been attempted to combat this problem. One of the most common techniques employed to functionalise these polymers is aminolysis. This requires physical adsorption on the surface and the use of carbodiimide coupling reagents. However, as these techniques often require multi-step reactions and laborious purification processes, these delivery systems have seen little success in clinical translation. To meet these challenges, herein, we introduce a new way to synthesize polyester polymers with tailored functionals. Choosing a heterobifunctional initiator allowed us to fabricate PCL polymer with clickable terminal groups for conjugation to biomolecules at physiological conditions, in the absence of coupling agents, using copper-free click chemistry. Thus, we simplified and eliminated the need for post-functionalisation process and multistep of conjugation and purification steps. We demonstrated this via the fabrication of microcarrier system, using membrane emulsion technique, and conjugated human serum albumin via a single step. We also showed the conjugation step is highly specific and rapid at physiological conditions. This new platform has the potential to develop a variety of polyester based biomaterials for application in tissue engineering and regenerative medicine.

Department of Prosthodontics, School of Dentistry, Faculty of Health Sciences, Aristotle University of Thessaloniki, Thessaloniki, GR-54124, Greece

Oral Mesenchymal Stem Cells (MSCs) have been extensively studied for their biological properties and ability to be applied for the regeneration of hard and soft oral tissues in a wide range of in vitro and in vivo pre-clinical models over the last ten years. These studies have acted as decisive milestones enabling translation towards their clinical application in Regenerative Dentistry, as surrogate therapeutic modules for conventional, biomaterial-based treatment modalities currently used to restore damaged tissues. To this end, implementation of well-designed clinical trials will pave the way for the exploitation of these research achievements in daily dental practice. In this presentation, we will describe the standard operative procedures (SOPs) for the safe and efficient clinical-grade expansion of oral stem cells for application in Dentistry, focusing on our Institutional experience on the development of tissue-engineered constructs tailored to be applied as Advanced Therapy Medicinal Products (ATMPs) for the regeneration of periodontal and peri-implant tissues. Regulatory hurdles in European Union, as opposed to increasing societal needs for applications of cellular therapies in Dentistry, as well as solutions for fostering wider patient access will be also discussed.
Nucleus pulposus progenitor cells positive for receptor angiopoetin-1 alias Tie2 – Multipotent cells of specific capabilities for tissue engineering?

B. Gantenbein¹,²,³

Stem cell therapy of the intervertebral disc (IVD) is one of the most warranted but also highly disputed procedures to be applied for treatment of degenerated discs that in many cases cause high low back pain. From previous studies it is known that for instance notochordal cells, a relatively large cell type containing a high number of vesicles, are highly regenerative [1] and may stimulate other differentiated cells, such as nucleus pulposus cells (NPC) to produce more matrix. Lately, a particular tissue-specific progenitor cell population has been identified in the center of the intervertebral disc (IVD), so-called nucleus pulposus progenitor cells (NPPC) [2]. The current hope is that these NPPC could play a particular role for IVD regeneration and/or delay of it. The current knowledge on these cells is obscured and their specific requirements for ex vivo culture are not very clear. Current evidence confirms the presence of these cells in murine, canine, bovine and in the human fetal/surgical samples [3]. Interestingly, Tie2 is a marker for endothelial cells and it is not very clear what their origin and their role might be. Current data using a combination of molecular assays could identify these with about 2-5% in bovine coccygeal IVD samples of one-year age. In human surgical specimens their presence is more obscured depending on the donor’s age and the particular condition of the IVD (e.g. based on Pfirrmann grade) [2, 3]. Here, I revisit the recent literature on regenerative cells identified for the IVD in the past decades. Current evidence how these NPPC can be isolated and detected in various species and tissues will be recapitulated. These NPPC are interesting to elaborate more closely from a developmental biology but also from an evolutionary point of you. Future directions will be provided how these progenitor cells could be used for regenerative medicine and tissue engineering.

Open up! Chances and limitations of using open innovation in science
B. Missbach
Presenting Author: Benjamin Missbach, benjamin.missbach@lbg.ac.at
1Ludwig Boltzmann Gesellschaft, Open Innovation in Science Center

INTRODUCTION: Open research in clinical settings not only refers to open data or open access research artifacts (e.g.: open access publications, open data, open peer-review), but it also includes openness during the entire research flow: From identifying research questions, co-creating study designs with relevant stakeholders, implementing research with patients reported outcomes sets, and utilizing research data for translating scientific knowledge into innovation. This is why the Austrian research organisation Ludwig Boltzmann Gesellschaft has now transformed into an institution that allows for the extensive application of Open Innovation in Science (OIS) methodology. What are the chances and what are the pitfalls of applying these concepts?

METHODS: Open Innovation is a concept formerly used in economic contexts. By making the organizational boundaries more permeable, internal R&D can be stimulated and spark innovation. While this concept is already applied in many businesses, the scientific system is now starting to use open innovation methods to fuel innovation in science.

RESULTS & DISCUSSION: With the OIS Center, the Ludwig Boltzmann Gesellschaft has created an experimental space for applying OIS and experimenting with different OIS methods. This ranges from opening up the research process at the stage of identifying new research questions (Crowdsourcing) and applying innovative team building methods (Ideas Lab) and finally working with methods and principles that allow to open up research processes. This approach has the potential to change how research organisations can structure their processes in order to create more impact for and with society. The first international crowdsourcing project “Tell us!” is an innovative approach to form research groups based on crowdsourcing research questions on mental health, identifying key issues and topics and finally establishing two strong research groups on the topic “Children of mentally ill parents”. The second crowdsourcing project aimed to identify new research questions in the diagnosis, treatment and rehabilitation of accidental injuries. With this approach, we aimed to identify research questions in a clinical setting by involving patients and experts (Caregivers, therapists, MDs) in order to spark innovative research projects.

CONCLUSIONS: Open Innovation in Science can lead to an increase in societal impact and the relevance to industrial and clinical applications. Open collaboration during one or several of those phases can involve citizen science, multidisciplinary research or strengthen the link between academia, industry and market needs. In order to follow this avenue of opening research, traditional scientific approaches need to be adapted and re-thought.

Using biophysical cues for engineering cell morphology and function
B. Rolauffs¹
Presenting Author: Bernd Rolauffs, bernd.rolauffs@uniklinik-freiburg.de
¹G.E.R.N. Tissue Replacement, Regeneration & Neogenesis, Department of Orthopedics and Trauma Surgery, Freiburg University Medical Center, Albert-Ludwigs-University of Freiburg, Freiburg, Germany

Biophysical cues can be as important as biochemical and genetic factors in controlling cell fate. However, compared to growth factors or other biochemical factors, biophysical stimuli are potentially easier to license for clinical use and, thus, harnessing biophysical stimuli for directing cell fate is a powerful and modern strategy for generating therapeutic or preventive interventions. The vision to control cell fate through controlling cell shape is an emerging “hot” topic in regenerative medicine that relies on better understanding, measuring, and controlling cell shape, in order to develop effective, biophysically acting cell-instructive materials. In this context, we have developed an automated, non-destructive, high-throughput quantification method, using images of calcine-stained cells, combined with binary thresholding, to calculate a specific panel of so-called quantitative shape descriptors for efficiently and accurately measuring cell morphological parameters of a large number of cells [1]. Recently, our group demonstrated that a given biomaterial type and its associated nanoscale stiffness are associated with a specific baseline cell morphology of human mesenchymal stromal cells (MSCs), and, thus, that one can intentionally generate desired baseline shapes by choosing biomaterial type and stiffness [1]. We then demonstrated in [2] that defined variations in externally applied biomechanical forces can also prompt a subsequent, defined change in MSC shape. By applying various cyclic tensional forces we engineered significantly different MSC shapes. Interestingly, the key to biomechanically engineering cellular shape was the repetition of a chosen stretch regimen, as cyclic tension had complex time- and amplitude-dependent effects on cell shape. Thus, biomechanically engineering cell shape (and the associated MSC differentiation) relied on complex non-linear processes that were dependent on both active stress input and inactive response time. This was in accordance with [1], which demonstrated that MSCs can be elongated during cyclic stretch, but, after cessation of stretch, the shape reverted back toward the initial baseline shape determined by the biomaterial type and stiffness. It is important to the field that, in the chosen experimental system, dynamic tensile forces were shown to be more significant in defining MSC shape than biomaterial stiffness-related cues – however, the ability of cyclic stretch to override the biomaterial-dictated shape was temporary, as MSC shape ultimately reverted back to the biomaterial-dictated baseline shapes. Together, these studies highlight that MSC shape can be statically engineered through using i. e. micro-engineered adhesion sites, but MSC shape can also be highly dynamic. Under biomechanically dynamic conditions, such as in a patient’s body, MSC shape can be intentionally engineered by utilizing the dynamic forces experienced in vivo.

Multi-modal imaging of soft and hard tissues in health and disease
B. Müller
Presenting Author: Bert Müller, bert.mueller@unibas.ch
Biomaterials Science Center, University of Basel, Allschwil, Switzerland

Caries is the most frequent disease worldwide. The currently available treatment options include isotropic fillings, which do not resemble the unique structure of enamel and dentin. X-ray imaging is not only a prerequisite to design bio-inspired dental fillings but also to verify, how far the recently introduced peptide-based remineralization of white spots allows for biomimetic regeneration. The same imaging techniques, i.e. micro computed tomography and spatially resolved small-angle X-ray scattering are used to characterize soft tissues down to the nanometre scale. Using the example of human brain tissue, the author’s team has launched nano-holotomography for the isotropic three-dimensional visualization of paraffin-embedded blocks of millimetre size. Nano-holotomography bridges the gap between the optical and electron-based microscopy techniques, while giving access to volumes of reasonable size with a spatial resolution well below 100 nm. This hierarchical imaging approach is going to mediate prospering nano-anatomy of human tissues in health and disease. Even simpler experimental setups enable us to three-dimensionally image entire peripheral nerves after repair and reconstruction. Using a laboratory-based micro computed tomography system, one can obtain three-dimensional data non-destructively, which allow for the characterization of nerves inside state-of-the-art conduits. These data also support the selection of cutting planes for the histological sectioning. The combination of the non-destructively obtained tomography data and the subsequently generated histology data gives rise to discoveries, which cannot be received by one technique alone. Furthermore, the information from the more-detailed two-dimensional histology data can be extended into the third dimension through conventional micro computed tomography.
Demineralized bone matrix as a promising carrier for local drug release
B. Wildemann
Presenting Author: Britt Wildemann, britt.wildemann@med.uni-jena.de
Experimental Trauma Surgery, University Hospital Jena, Germany, Julius Wolff Institute & Berlin Brandenburg Center for Regenerative Therapies, Charité-Universitätsmedizin Berlin, Germany

The research and development of materials for bone grafting and local drug release increased in the recent decades. The developed materials are often very complex, making translation into the clinic difficult. A clinically well-established grafting material is allogeneic bone, especially demineralized bone matrix (DBM). We aimed at investigating and optimizing the properties of various demineralized bone matrix products for simple clinical use by quantifying the amount of growth factors and evaluating the osteoinductive properties in vitro and in vivo in critical-size defect models. The quantity and composition of growth factors varied between the donors/lots and different commercial DBM-products. Alkaline phosphatase activity, as an indicator for osteoinductivity, was induced in C2C12 cells when cultured with DBM. In a critical-size rat defect model, bone healing was stimulated without complete bridging. The loading of DBM with bone morphogenetic protein-2 (BMP-2) revealed a burst release within the first 7 days, but also a depot storage of the active growth factor over 56 days. Using this enriched DBM for the filling of drill hole defects in a sheep model showed the regeneration of the defect after 63 days with a reconstitution of the native metaphyseal bone structure. With this in-depth analysis of the DBM properties, limited osteoinduction was observed in vivo, which can be overcome by enrichment with BMP-2. The advantage of this combination is the approval of both components, the ease perioperative loading, and the burst release of BMP-2 in combination with a long-term activity of the factor.
Dynamic biomedical systems based on elastin-like recombinamers
J.C. Rodríguez-Cabello
Presenting Author: J. Carlos Rodríguez-Cabello, roca@bioforge.uva.es
BIOFORGE Laboratory. University of Valladolid CIBEER-BBN. Valladolid, Spain

The use of recombinant technology in the production of macromolecule-based advanced biomaterials has caused a breakthrough increase in achievable degree of complexity and control on the molecular designs and compositions. Those recombinant macromolecules of polypeptide nature are called recombinamers. They are produced from a purely synthetic gene, in which the amino-acid sequence is not restricted to naturally occurring proteins and it is dictated only by engineering design parameters. The high degree of complexity and control of the recombinamer compositions permit to reach unmatched levels of functionality in the materials produced by this way and on the systems based on them. The development of functionality in such systems comes by to different ways. In one hand, these materials can display direct functionality. Such functionality is based on the presence in their composition of functional epitopes, typically inspired by functional epitopes found in natural proteins. The other source of functionality is the holistic functionality that emerges by the precise combination and interactions of direct functions in a precise and well designed macromolecular composition. This holistic function is particularly evident in system with a dynamic nature; systems that rearrange and respond to changes in their environment. Examples of such dynamic systems will be presented. The examples will expand from complex 3D structures for regenerative medicine and tissue engineering that are able to incorporate a designed program of degradation profile and time evolution to more fundamental questions such as the hierarchical spontaneous development of morphology and macroscopical shapes in natural and artificial systems.
Biomaterial scaffolds as 3D tumour models for cancer research
C.M. Curtin 1,2,3
Presenting author: Caroline M. Curtin, carolinecurtin@rcsi.ie
1Tissue Engineering Research Group, Dept. of Anatomy, Royal College of Surgeons in Ireland (RCSI), Dublin, Ireland 2Trinity Centre of BioEngineering, Trinity College Dublin (TCD), Ireland 3Advanced Materials and Bioengineering Research Centre (AMBER), RCSI and TCD, Dublin, Ireland

Culturing of cancer cells in 2D has traditionally been used to study complex tumorigenic mechanisms but lacks the structural microenvironment required for cell-cell and cell-extracellular matrix interactions. The alternative involves animal xenograft models but also has various limitations. Recently, 3D cancer cell culturing has been proposed to bridge the gap between conventional 2D culture and in vivo tumours by enabling cells to acquire phenotypes and respond to stimuli similar to in vivo biological systems. Furthermore, gene therapy, encompassing plasmid DNA, microRNA and siRNA delivery, has emerged as a potential therapeutic for cancer treatment as genes can be released locally for a defined timeframe. However, effective gene delivery to abrogate tumour growth remains a crucial barrier to its clinical application. This presentation will describe studies that aimed to develop and characterise 3D in vitro culture models of cancer to simulate the primary tumour and secondary cancer bone metastasis, and to then use the models to determine the efficacy of nanoparticle-mediated gene delivery as competent anti-cancer platforms. Collagen-based scaffolds capable of supporting cell culture have been widely used as gene delivery platforms for tissue engineering and regenerative medicine within our laboratory. Features include excellent biocompatibility and a 3D structure capable of recapitulating the native tumour geometry demonstrating their potential as extracellular matrix models due to their biomimicry. Preliminary work has already demonstrated successful nanoparticle-mediated siRNA delivery in 3D collagen-nanohydroxyapatite scaffolds simulating prostate cancer bone metastasis [1, 2]. Additionally, these scaffolds together with collagen-glycosaminoglycan scaffolds have been used as 3D neuroblastoma models that correlated more closely with in vivo xenograft tumours compared to 2D monolayer cell culture [3]. We hypothesise that collagen scaffolds may be used as 3D in vitro “tumours” that mimic characteristics of in vivo primary tumour progression while collagen-nanohydroxyapatite scaffolds may serve as bone templates for the study of metastasis as the bone component, hydroxyapatite, may be involved in metastasis pathogenesis. Furthermore, these gene delivery scaffold-based models may serve as excellent tools for the development of novel treatment targets.

Multifunctional glycosaminoglycan hydrogels for new therapies and human disease models
C. Werner
Presenting author: Carsten Werner, carsten.werner@tu-dresden.de
Max Bergmann Center of Biomaterials (MBC) and Center of Regenerative Therapies Dresden (CRTD), Leibniz Institute of Polymer Research Dresden (IPF) and TU Dresden, Dresden, Germany

Glycosaminoglycans (GAGs) govern important functional characteristics of the extracellular matrix (ECM) in living tissues and the incorporation of GAGs into biomaterials was shown to open up new routes for the effective modulation of various signaling molecules. For further expanding the related options, we have introduced a rational design strategy for creating biohybrid hydrogels based on GAGs of varied sulfation patterns (heparin and selectively desulfated heparin derivatives), multi-armed poly(ethylene glycol) and a range of functional peptides (to mediate MMP driven reorganization, for covalent in situ assembly of gels from polymeric precursors, and to serve as ligands of cell adhesion receptors). The theoretically predicted decoupling of biochemical and mechanical gel properties was confirmed experimentally and applied for implementing GAG-based biofunctionalization schemes using a broad range of combinations of cytokines. Micro-processing schemes (cyro-gelation, solvent-assisted micro-molding, microfluidic microgel fabrication, multicomponent inkjet bioprinting,) were recently established to allow for the fabrication of GAG-based hydrogels for multiphasic and multifunctional gel materials capable of providing spatiotemporally adjusted signaling characteristics. Applications of the materials platform include 3D culture models to study the role of exogenous cues in fate control of bone marrow derived human stem and progenitor cells, to explore breast and prostate tumor vascularization in vitro as well as scaffolds for exploring new therapeutic approaches to chronic wounds and to neurodegenerative diseases.
Open access publishing: Benefits and challenges
C. Da Re
Presenting Author: Caterina Da Re, caterina.dare@frontiersin.org
1Frontiers Media, Lausanne, Switzerland

One option for authors who wish to make their work openly accessible is to publish in a journal that makes your work immediately and permanently available online for everyone, worldwide. Open access (OA) is a step towards the democratization of scientific literature. By taking advantage of the digital revolution, OA exploits the interconnected world in order to provide free access and reuse of scientific literature for potentially everyone in the world. The “liberty of re-utilization” drastically promotes the spreading of scientific knowledge and its validation, making OA an efficient system for promoting scientific research. In particular, the Green OA assumes that scientists can publish their achievements in a “closed” journal - the lector should pay to read it - without paying any fees. However, at the same time, these contents are “open”, meaning available, in a sort of archive for everyone to read and share. The counterpart of the Green OA is the Gold OA, which implies paid journal publication from the authors but free of charge accessibility to the journal itself. Currently there are major issues about the publishing fees that need to be covered by the authors. The costs of producing an article are somewhat fixed and cover among others manuscript editing, formatting, standardizing, indexing, etc. The introduction of the electronic format has allowed to significantly reduce these expenses, but they still remain a cost that needs to be covered to allow quality publications. There is much room for imagination: some publishing houses only publish OA journals, and some publish a mix of OA and subscription journals, whereas other subscription journals open up or restrict the access after a certain period of time. From another perspective, some journals charge article processing fees (paid by authors or by their grant makers, referred to as the author-pay model) and some receive funding from foundations or institutions, while other journals are based on advertising revenues, priced add-ons, or auxiliary services. Lastly, it is important to point out that OA is compatible with peer review, and all the major OA initiatives for scientific and scholarly literature insist on its importance. Just like subscription-based journals, open access journals must maintain high quality standards of publications in order to be competitive.
Mesenchymal stem cell encapsulation in alginate micro-particles for intra-articular injection in osteoarthritis
C. Le Visage
Presenting Author: Catherine Le Visage, catherine.levisage@inserm.fr
Inserm Regenerative Medicine and Skeletton (RMeS U1229), Université de Nantes, Nantes, France

Osteoarthritis (OA) is a degenerative and inflammatory joint disease that affects the whole joint. Mesenchymal stem cells ability to secrete anti-inflammatory and immuno-modulatory factors represents an attractive tool in the treatment of OA. Considering the risk of cell leakage and the massive cell death upon intra-articular injection, we developed a micromolding method of encapsulation that allows to obtain particles that (i) could be injected with a 26G needle into a mouse joint and (ii) could provide a 3D microenvironment supporting cell biological activity and could. Polydimethylsiloxane (PDMS) chips containing circular micromolds were manufactured and a solution of 2% alginate containing human adipose stem cells (3 M/mL) was deposited on the molds. Cell loading into the micromolds was performed either by sedimentation or by centrifugation. After Ca²⁺ crosslinking, alginate particles (diameter 150±0.7μm) were obtained. The number of cells per particle was 5 times higher when the micromolds were loaded by centrifugation. Cell number and metabolic activity remained stable for 7 days after encapsulation and injection through a 26G needle had no impact on cell viability. When cells were stimulated with TNF-alpha and INF-gamma, prostaglandin E2 (PGE2) concentration in the supernatant was multiplied by 13 and 7 and indoleamine2,3-dioxygenase (IDO) activity was 2 and 4 times higher when cell loading was performed by sedimentation or centrifugation, respectively. To conclude, we have demonstrated that encapsulated cells were able to sense and respond to an inflammatory stimulus and their potential will now be evaluated in a murine model of osteoarthritis.
Patient-specific meniscus replacement: Roadmap from artificial over tissue-engineered to smart meniscus
C. Van Der Straeten
Presenting Author: Catherine Van Der Straeten; e-mail: Catherine.vanderstraeten@uzgent.be
1Health innovation and Research Institute, Ghent University Hospital, Ghent, Belgium

The fibrocartilaginous menisci between the femoral condyles and the tibial plateau of the knee are essential for the biomechanical and biological homeostasis of the joint and the articular cartilage. They are important for shock absorption, load distribution in weight bearing conditions by increasing the contact area of the opposing articular surfaces, joint stability and lubrication, and articular cartilage nutrition. However, they are often injured and difficult to repair. Meniscal tears are commonly seen in young adults as a result of sports injuries. In the older population, meniscal degeneration, with loss of meniscal tissue and function, plays an essential biological role in the development and progression of osteoarthritis (OA). In vitro pro-inflammatory stimulation of injured meniscal tissue causes production of cytokines, chemokines, matrix degrading enzymes and other catabolic factors by meniscal cells. This effect may be enhanced by obesity and/or age-related dysregulation of anabolic gene expression and changes in cytokine release. Radiographic signs of OA are noted at 8-16 years post-meniscectomy whilst cartilage loss on MRI has been shown at 7 years after meniscectomy. Surgical treatments aim either to repair the menisci in cases of tears or to decrease the loads on the articular cartilage by replacing meniscal tissue or altering joint alignment in severe injuries and/or degeneration. The treatment of meniscus lesions is still the most frequent procedure carried out by knee surgeons (over 1 million annually in the USA). However, clinical results of meniscal implants (allografts and artificial menisci) vary and are difficult to evaluate because surgical and fixation techniques, implant materials, clinical evaluation, scoring systems and criteria for failure differ significantly among publications. In a nutshell, they usually offer symptomatic relief but do not prevent or delay the progression of OA [1]. There is an urgent need to overcome traditional strategies and treatment options. New knowledge and innovative methods are required to develop a patient-specific medically implantable meniscus which will improve the immediate outcome of the surgery, whilst stimulating and expediting regeneration of the injured tissue focusing on innovative and interdisciplinary principles. We present a roadmap to develop a patient-specific 3D printed meniscal implant, using a novel polymer/polymer-composite (PBM patented toolbox) in a fully artificial meniscus and a tissue-engineered implant, being tested for biocompatibility, biodegradability, biotribology and biomechanical properties. We have demonstrated that high-throughput production of uniform micro-tissues is promising for the generation of larger scale tissue engineering constructs [2]. We now focus on micro-aggregates with different cell types and co-cultures of fibro-chondrocytes with mesenchymal stem cells. In parallel we will investigate the best in vivo imaging method for meniscus (CT-MRI), perform statistical shape modelling of menisci and develop an algorithm for fast segmentation and subsequent patient-specific 3D printing. A plan for preclinical testing in an animal model (sheep) and clinical trials will be laid out. Finally, the use of sensor/lab-on-chip technology for the development of a smart meniscus enabling close monitoring and early intervention to prevent failure, will be explored.

Subchondral bone remodeling concurrent with cartilage degeneration in osteoarthritic joints
C Liu1,2
Presenting Author: Chaozong Liu, Chaozong.Liu@ucl.ac.uk
1UCL Orthopaedic Bioengineering Research Group, Division of Surgery and Interventional Science, University College London, Stanmore HA7 4LP, UK 2Royal National Orthopaedic Hospital, Stanmore HA7 4LP, UK

Osteoarthritis (OA) is a degenerative joint disease that affects both cartilage and subchondral bone [1]. With progression of OA, as results of changes in the loading pattern, bone remodelling and resorption occur in the joint [2]. This weakens the physical environment that supports the overlying cartilage [3]. In this study, we examined the changes in local distribution of volumetric bone mineral density (vBMD) in the subchondral bone, and the biomechanical properties of the overlying cartilage with an aim to understand the effect of subchondral bone remodelling on the overlying cartilage degeneration. Human femoral heads were collected during total hip replacement operation due to OA. Cartilage was graded using ICRS classification, and the mechanical property of cartilage was measure by non-destructive cyclic indentation. To determine the remodelling of the subchondral bone, a peripheral quantitative CT (pQCT) was used to assess the vBMD distribution within the subchondral bone. Non-parametric Kruskal-Wallis method was used for statistical analysis (p= 0.05). The examination of retrieved tissues revealed cartilage in different stages of degeneration, from normal to severely abnormal. Subchondral vBMD decreased with cartilage ICRS grade from 576 to 253mg/cm³ confirming bone remodeling in all samples. Dynamic modulus of cartilage was mapped and showed a weak positive correlation to ICRS grades (3.34±0.93, 2.86±1.11, 4.64±4.37 and 5.56±1.83 N/mm for grade I,II,II and IV respectively), and a moderate positive correlation to subchondral vBMD (r=0.59), confirming the concurrence of cartilage biomechanics, degeneration and SCB remodelling. It is believed that that the degeneration of cartilage altered the loading regime in the subchondral bone, leading to bone remodeling, resorption and even cyst formation in the weight-bearing regions of subchondral bone. This changed the physical environment supporting the overlying cartilage, which may lead to further cartilage degeneration

Osteoporosis and 3D bone like scaffolds mimicking the features of human healthy bone
C. Vitale-Brovarone
Presenting author: Chiara Vitale-Brovarone, chiara.vitale@polito.it
Applied Science and Technology Department, Politecnico di Torino, Italy

Osteoporosis is a worldwide spread, bone disease which is continuously increasing due to population ageing; it leads to bone mass loss and increased porosity resulting in fragility fractures. In order to treat osteoporotic fractures and to better understand osteoblast and osteoclast cross-talking, 3D scaffolds mimicking the features of human healthy bone have been developed. Healthy and osteoporotic bones obtained from human bone tissues discarded during surgical interventions have been fully characterised through micro-CT scans, nanoindentations, XRD spectra, Raman spectroscopy and immunohistochemistry. STL files were obtained and used to 3D print a type I collagen solution containing mesoporous bioactive glass/nano-hydroxyapatite particles to mimic both the organic and the inorganic phases of human bone and to stimulate bone regeneration. The rheological properties of the Type I/inorganic particles suspensions were investigated at different collagen concentrations and temperatures as several cross-linking methods have been explored. The incorporation of bone growth factors (GF) in the scaffold struts was carried out using several approaches including ink-jet printing, GF loading into mesoporous glass with enlarged nanoporosity and encapsulation in polymeric nanospheres. Different co-culture of osteoblasts and osteoclasts set-ups were explored and used to assess the influence of the developed 3D scaffolds and their chemical and topographical stimuli on the osteoblast-osteoclast coupling.

ACKNOWLEDGEMENTS: This project has received funding from the European Research Council (ERC) under the European Union’s Horizon 2020 research and innovation programme (grant agreement No 681798-BOOST) and by the Italian Minister of Research, Progetto FARE Ricerca in Italia (GRACE).
Tailoring Laponite® crosslinked hydrogels to control cell function in vitro and in vivo
C. Sammon
Presenting Author: Chris Sammon, c.sammon@shu.ac.uk
Materials and Engineering Research Institute, Sheffield Hallam University, Sheffield, UK

Tissue engineering scaffolds which promote regeneration offer potential therapeutic solutions for musculoskeletal tissues and also afford routes to a range of 3D culture matrices. Hydrogels in particular, offer significant potential as a choice of biomaterial for tissue engineering, due to their hydrated nature, matched mechanical properties, biocompatibility and extensive structural framework which can be chemically tailored to mimic the in vivo extracellular matrix (ECM). In this presentation a family of Laponite® crosslinked pNIPAM hydrogels developed in our group will be discussed. These materials have thermal responsive properties close to body temperature, are fully reacted in a liquid state where cells and other factors can be incorporated and require no clean up prior to injection. The presentation will show how it is feasible to fully tailor their mechanical and morphological properties by careful selection of the hydrogel composition and drive the differentiation of human mesenchymal stem cells towards predetermined phenotypes for a range of clinical applications [1,2]. Data will also be presented demonstrating that these materials can be used to generate in vitro 3D culture models of human intestinal epithelium. By careful selection of the culture conditions a range of cell morphologies including villus-like structures can be produced [3].

ACKNOWLEDGEMENTS: Financial support was received from EPSRC (EP/H000275/1, EP/1016473/1), MRC (MR/P026796/1) and ARUK (Project no. 21497).

Injectable hydrogels for musculoskeletal system regeneration: Importance of the disease microenvironment
C.L. Le Maitre

Presenting Author: Christine Le Maitre, c.lemaitre@shu.ac.uk

1Biomolecular Sciences Research Centre, Sheffield Hallam University, Sheffield, UK

Injectable hydrogel systems have been proposed as an interesting mechanism of delivery of stem cells to promote musculoskeletal tissue regeneration. Our laboratory has developed a platform technology which can be tailored to induce stem cell differentiation to intervertebral disc cells (NPgel) or bone cells (Bgel). During the design of regenerative approaches for musculoskeletal tissues it is essential to consider the microenvironment and native cell behavior within the site of injection. During degenerative conditions such as intervertebral disc degeneration the intervertebral disc becomes a hostile environment for cells. With a poor nutrient supply, hypoxic environment and low pH the survival of injected cells may be under question. Furthermore the degenerate niche is characterized by high levels of catabolic cytokines which increase matrix degradation and decrease normal matrix synthesis. Thus the effects on any injected cells must be determined otherwise addition of further cells to this hostile environment could further degrade rather than regenerate the native tissue. Here we will discuss the behavior of stem cells within our NPgel system cultured under conditions which mimic the degenerate niche. For the regeneration of any musculoskeletal tissue, consideration of the age of the patient must be considered where acellular approaches which depend on the native cells to induce repair (e.g. in bone repair) or where autologous stem cells are applied. Aged individuals have a reduced ability to heal and regenerate and thus success and limitations of autologous cell sources must be considered. We have demonstrated that our Bgel system could improve bone healing in aged individuals without the need for additional cell sources.

Development of collagen/hyaluronic acid composites for the treatment of nucleus pulposus degeneration: A physico-chemical study

C. Hélary

Presenting Author: Christophe Hélary, christophe.helary@upmc.fr

Back pain is considered as the disease of the century because 90% of the world population will be affected during its lifespan. In 50% of cases, chronic back pain is associated with intervertebral disc (IVD) degeneration. The current treatment is based on physiotherapy and administration of drugs. When the pain is too great, a spinal fusion or a discectomy are required. Novel treatments relying on the injection of stem cells embedded in injectable biomaterials have emerged with the aim of regenerating the Nucleus Pulposus (NP) [1]. As the cell behavior depends on the biochemical, mechanical and topological environment, a biomimetic hydrogel would promote IVD regeneration by providing cues to cells to differentiate into a physiological phenotype. Nucleus Pulposus is a hyper hydrated tissue working as a hydraulic shock absorber. Glycosaminoglycans give a high degree of hydration to NP whereas collagen II gives resistance and allows for cell adhesion [2]. With the aim of developing novel biomimetic hydrogels, collagen/hyaluronic acid composites were synthesized to mimic the structure and the mechanical properties of Nucleus Pulposus. For this purpose, different methods to associate hyaluronic acid with collagen were tested and the impact of the formulation on physical properties of composite hydrogels was analyzed. As HA does not spontaneously form gels, it was functionalized with tyramine (Tyr) groups to allow HA-Tyr gelling. This gelling was based on an enzymatic crosslinking by Horse Radish Peroxidase (HRP) and H₂O₂. On the other side, collagen gelling was triggered by pH increase leading to the formation of collagen fibrils populating a physical hydrogel. With a constant collagen concentration (0.4%), HA-Tyr was increased up to 2% and different HRP and H₂O₂ concentration were used to modulate both kinetic and degree of crosslinking of hydrogels. This physico-chemical study revealed the impact of the different parameters on the physical and biological properties of hydrogels. Two regimes were observed. At low HA-Tyr content (less than 0.4%), the composite behavior was driven by collagen as HA-Tyr was not able to form a chemical gel at this concentration. Hydrogels exhibited a fibrillary network consisted of cross striated fibrils. The presence of HA-Tyr and a high gelling speed slightly decreased the mechanical properties of composites. From 0.8%, a regime driven by HA-Tyr appeared. The mechanical properties were improved when the HA-Tyr concentration, the gelling speed and the cross-linking density rose. The mechanical properties and the hydration degree were close to those of NP. Unfortunately, this was associated with an inhibition of collagen fibrillogenesis. To evaluate the ability of composites to promote cell adhesion and proliferation, fibroblasts were encapsulated within HA-Tyr/collagen hydrogels. A high HA-Tyr content and the gelling speed negatively impacted cell adhesion and proliferation. This study shows that synthesizing a biomimetic composite hydrogels requires compromises. When the HA-Tyr and gelling speed raise, mechanical properties and hydration are improved but collagen fibrillogenesis and cell adhesion are slightly inhibited. A low gelling speed and a 0.8% HA-Tyr content is the most appropriate formulation to mimic NP.

Advanced therapy medicinal products (ATMPs) are currently experiencing a boom with several products reaching the market and many others under various stages of nonclinical and clinical development for a broad range of conditions. Tissue-engineered products (TEPs) are a promising subclass of ATMPs for regenerative medicine that can potentially address unmet clinical needs. Here we highlight some of the regulatory considerations and complications of developing TEPs and bringing innovative products to market. To identify several of the most challenging areas of regulatory impact on TEP development we have reviewed guidelines pertinent to both European (EMA), US (FDA) and global (ICH) development of TEPs, the literature and our own experience. The following aspects were identified as important regulatory considerations for the development of TEPs.

Classification: most TEPs are borderline products and correct classification can define which regulatory path a product takes and which studies might be required to support clinical development. Free of charge regulatory procedures exist to formally classify ATMPs. Combination: many TEPs are a combination of cells plus a medical device, such as a scaffold or encapsulation material, for example. As medical devices are regulated differently to medicinal products, correct classification, performance and safety testing may be required whereas different documents may also be required at the time of regulatory submission. Manufacturing: there are many potential regulatory issues associated with manufacture of TEPs including scale-up capacity from laboratory to clinical/commercial scale, pharmaceutical acceptability of materials and excipients including traceability and viral safety. New approaches such as 3D printing are not always clearly covered by legislation or guidelines. Characterization: TEPs, especially those combined with a medical device, may be difficult to characterize once combined, for example, cells once encapsulated or integrated in a scaffold, which creates regulatory challenges for assuring safety and mechanism/performance. Relevant species: many TEPs may be considered as personalized medicines as they use autologous cells as an active substance that complicates the design of nonclinical studies, especially toxicity. Allogeneic cells are preferred from a manufacturing point of view, but are not always feasible. Furthermore, human cells are xenogeneic in mice whereas many scaffolds may also be derived from other animal materials such as pig meaning many studies require immunocompromised animals. Finally, recreating the clinical route of administration in animal models can also be challenge and require regulatory input to assure an adequate design. As the number of ATMPs and TEPs under development continues to grow and as new technologies are incorporated into their design, more exceptions and challenges to the current regulatory requirements occurs. TEP development can benefit from continuous regulatory input.

Carbohydrate polymers to modulate macrophage activities for tissue regeneration and immunotherapy
C. Wang

Presenting Author: Chunming Wang, cmwang@umac.mo

1Institute of Chinese Medical Sciences, University of Macau, Macau SAR, China

Macrophages are traditionally best known as chief defenders of our immunity. In fact, they play diverse and essential roles in many other physiological and pathological processes, notably including tissue repair and biomaterials integration. They can accumulate at the tissue-biomaterials interface and secrete abundant cytokines to create a microenvironment that benefits or inhibits regeneration. Because the phenotype of these cells is highly plastic in response to varying stimuli, it may be feasible to manipulate their activity at the interface and harness their power to mediate tissue regeneration. Targeting the toll-like receptors (TLRs) on macrophages, our team have devised a series of carbohydrate polymers that can stimulate macrophages to secrete different sets of cytokines [1-3]. We demonstrated that two chemically modified glucomannans could stimulate macrophages to release pro-osteogenic or anti-cancer cytokines, respectively, and devised the first one into the coating of mesenchymal stem cell-laden hydrogels scaffold for osteogenesis. Also, through screening TLR-activating polysaccharides, we modified zymosan/beta-glucan onto titanium implants and assessed their efficacy of integration and potential safety following immune stimulation. Our future research will focus on distinguishing the roles of macrophages of various sub-types and origins in specific regenerative processes.

The application of bioengineering principles to evaluate emerging therapeutics for respiratory disease
C. O’Leary1,2,3
Presenting Author: Cian O’Leary, cianoleary@rcsi.ie
1School of Pharmacy, Royal College of Surgeons in Ireland, Ireland 2Tissue Engineering Research Group, Royal College of Surgeons in Ireland, Ireland 3Advanced Materials & Bioengineering Research (AMBER) Centre, Royal College of Surgeons in Ireland & Trinity College Dublin (TCD), Ireland.

In tandem with an ageing population and a lack of curative treatments, chronic respiratory disease persists as a leading cause of global mortality, morbidity, and economic burden. The clinical management for conditions such as chronic obstructive pulmonary disease (COPD), cystic fibrosis, and idiopathic pulmonary fibrosis primarily focus on symptomatic therapies, prompting the requirement for further discovery of disease-modifying medicines. Unfortunately, current preclinical models limit the successful translation of new therapeutics in the drug development pipeline, with either in vitro models of single-cell, two-dimensional cultures providing an oversimplification of respiratory tissue, or in vivo animal models lacking key characteristics of the human disease in question. As a result of the disconnect between pre-clinical in vitro models, animal models, and subsequent human trials, most potential drug candidates under investigation fail to exhibit the necessary safety and efficacy to positively influence patient outcomes [1]. Alternatively, bioengineered in vitro respiratory models can enable the exploration of critical features of airway conditions to investigate new mechanisms of disease, drug targets, and overall, bridge the in vitro-in vivo disparity in drug discovery [2]. These models can accurately simulate the complex multicellular environment of the airways, recapitulating the correct three-dimensional anatomical and physiological tissue arrangement that instructs cell behaviour through extracellular matrix (ECM)-ligand interactions and biophysical forces. Moreover, in the case of a particular disease, specific properties of these systems can be modified to parse the important pathophysiological mediators in a manner that is not feasible with current in vitro platforms or animal models. Essentially, by application of the tissue engineering triad, emerging therapeutics can be examined with greater accuracy to provide crucial detail at an earlier stage in the drug development process, facilitating greater use of resources and improving successful translation. Accordingly, the application of bioengineering principles to evaluate novel therapeutics for chronic respiratory disease will be discussed, using examples of tissue-engineered tracheobronchial models and substrates to explore new drug candidates identified in our laboratory.

Development of synergistic therapeutic biomaterials to manipulate bone metabolism and promote repair
C.M. Murphy1,2
Presenting Author: Ciara Murphy, ciaramurphy@rcsi.ie

Healthy bone metabolism is a tightly coupled dynamic process that relies on a balance between osteoclast driven bone resorption (catabolism) and bone formation (anabolism) by osteoblasts. Traditionally, tissue-engineering approaches for non-union fracture repair employ local anabolic therapeutic delivery strategies that target mesenchymal stem cells (MSCs) and osteoblasts to induce bone formation; however, the challenge of healing non-union defects depends on the cause of defect e.g. trauma or disease, and targeting bone formation alone is often insufficient for healing. Our research focuses on targeting both anabolism and catabolism to manipulate bone metabolism and promote bone repair. We have approached this through the synergistic use of both anabolic therapeutics, including recombinant human bone morphogenic protein (rhBMP) -2 and parathyroid hormone (PTH)(1-34), and anti-catabolic bisphosphonates (BPs) in order to manipulate bone metabolism. A major challenge with harnessing a combined dosing regimen is controlling the release of the individual therapeutics to target cells. We have developed a number of polymer-ceramic based biomaterial delivery systems, including both implantable scaffolds and injectable scaffolds, for the controlled release of these therapeutics and demonstrated their efficacy in vivo [1]. A dual therapeutic load of BMP-2 and BPs provided a synergistic enhancement of bone regeneration, demonstrating significantly increased bone formation and remodelling compared to anabolic therapies alone [2]. Incorporating hydroxyapatite in our scaffolds further increased bone formation, demonstrating our polymer-ceramic scaffolds to be osteoconductive in the absence of therapeutics. We have also investigated the manipulation of bone metabolism through a specific dosing regimen of PTH(1-34) to induce bone remodelling and drive healing in BP loaded fractures [3]. Our research to date has shown that optimising both the delivery and regimen of anabolic and anti-catabolic therapeutics to control bone metabolism, augments the bone regenerative potential of these therapeutics in orthopaedic applications. More recently, we have begun to investigate the potential of a number of bioactive ceramics to elicit an anabolic and anti-catabolic bone cell response, and have incorporated them within thermoresponsive collagen-based matrices to develop a range of minimally invasive therapeutic scaffolds that can manipulate metabolism and promote bone repair without the addition of drugs.

Three-dimensional (3D) printing of acellular, non biological material, is already widely used in surgery. In the biomedical field, this technology is in fact increasingly used to create custom-made implants, precise cutting guides, anatomic or models, and can greatly help surgeons in i) identifying specific anatomic variations in complex cases, ii) assisting in the planning of the surgery, or iii) performing precise cuts for bone removal. In recent years, the possibility to print biological materials (Bioprinting), including cells, has gained increasing interest in surgery. Bioprinting has the potential to fabricate living tissues and organs, by delivering biologic elements (not only cells, but also growth factors, drugs, cytokines) within a biomaterial scaffold in a pre-determined way [1]. Bioprinting is typically performed using bench-based sophisticated 3D printers, often in a sterile environment, and allow for the creation of multi-layered scaffolds with cell-to-cell interactions and matrix production [2]. Furthermore, new studies have described the design and applicability of surgical bioprinters, which can deliver, at the time and point of need, a biomaterial that can be deployed during surgery to repair or regenerate human tissues. Ideally handheld directly by the surgeon, this approach can potentially solve some of the difficulties encountered with bench-based constructs [3]. 3D printing and bioprinting now carry huge expectations from the surgical community, because it promises the potential regeneration of entire living organs and tissues. In this talk I will discuss the current state of the art in bioprinting from a surgical prospective, focusing on its application in the musculoskeletal field. I will highlight the current roadblocks for the application of this technique in clinical practice, as well as the expectations and the promises for the future seen with the eyes of the final user.

Mesenchymal stem/stromal cells - A novel therapeutic tool against infection
C.L. Esteves
Presenting Author: Cristina Esteves, cristina.esteves@roslin.ed.ac.uk
1The Roslin Institute, University of Edinburgh, UK

Increased bacterial resistance to antibiotics is recognized as a major threat to human and animal health. It is a growing problem in the horse, as reflected by a sharp increase over the last 20 years in the number of clinical bacterial isolates that are resistant to a variety of antibiotics. Therefore, addressing antimicrobial resistance (AMR) through more rational antimicrobial use and finding alternative/complementary approaches to antibiotic therapy has become an urgent priority for the management of acute and chronic infection both in humans and companion animals. An added concern with the use of antibiotics is that although effective in combating the cause of disease they do not address tissue damage in infection, which often resolves as fibrosis and scaring, making the tissue prone to re-infection and chronic disease. In humans, new approaches are already being developed that involve not only direct action against bacteria but also stimulation of host immunity and natural tissue healing [1]. Novel strategies harnessing the antimicrobial properties of MSCs are now at the frontline, with early phase clinical trials already underway for multi-drug resistant tuberculosis, Acute Respiratory Distress Syndrome and Chronic Obstructive Pulmonary Disease. Indeed, enormous excitement has been generated recently with the demonstration that MSCs effectively enhance bacterial clearance in preclinical models of infection, both through direct production of antimicrobials and through modulation of host immune cells, namely macrophages and neutrophils. Limited clinical data in domestic animals (dogs) has shown significant benefits in the treatment of drug-resistant skin infections. In the horse, two groups including ours [2,3] have shown that MSCs effectively respond to bacteria by secreting antimicrobials (e.g. Lipocalin-2) and immunomodulatory cytokines (MCP-1, CCL5, IL-6 and -8), significantly reducing growth and biofilm formation by Escherichia coli and Staphylococcus aureus in vitro. We observed these effects with MSCs obtained from different tissue origins, not only from bone marrow and adipose tissue, but also from endometrium, which is naturally exposed to infection. Equine MSCs have been used for musculoskeletal repair for over 15 years and are now the subject of a multimillion dollar business incorporating veterinary clinics and stem cell companies worldwide. However, their clinical potential extends beyond the musculoskeletal system, and their use in the combat of infection could be of great relevance not only in humans but also for treatment of companion animals, namely the horse.

Disease and traumatic injury can lead to skeletal muscle loss associated with functional impairment. The restoration of lost muscle tissue represents a big clinical challenge and there is urgent clinical need for novel treatment modalities for muscle bioengineering. The use of stem cells constitutes a promising strategy for the generation of autologous, implantable cells to repair damaged skeletal muscle. However, the early quality of the regenerated tissue is of critical importance for its accurate function and thus many efforts have been made to improve the in vivo cell survival and maturation. The muscle tissue development by optimizing the cell population, the nurturing microenvironment and stimulating function are being explored. Current limitations are cellular dedifferentiation, low vascularisation and lack of innervation. Early stimulation using electrical, mechanical and pharmacological stimuli can be used to increase muscle function and performance. Our lab has shown that magnetic stimulation supports muscle and nerve regeneration by activating the neuronal cellular machinery, increasing nerve-muscle cross-talk and inducing the maturation of newly formed neuromuscular junction [2]. In addition, we could show that injected human muscle precursor cells over expressing peroxisome proliferator-activated receptor gamma coactivator 1-alpha (hPGC-1α) enhanced the functional muscle regeneration after trauma [2].

Bioprinting for bone and joint regeneration
D. J. Kelly
Presenting Author: Daniel J Kelly, kellyd9@tcd.ie
Trinity Centre for Bioengineering, School of Engineering, Trinity College Dublin, Ireland

Our musculoskeletal system has a limited capacity for repair. This has led to increased interest in the development of tissue engineering strategies for the regeneration of musculoskeletal tissues such as bone, ligament, tendon, meniscus and articular cartilage. This talk will review our attempts to use biomaterials and mesenchymal stem cells (MSCs) to bioprint functional articular cartilage and bone grafts for use in bone and joint regeneration. It will begin by describing how 3D bioprinting can be used to engineer biological implants mimicking the shape of specific bones, and how these bioprinted tissues mature into functional bone organs upon implantation into the body. Next, it will be demonstrated that different musculoskeletal injuries can be regenerated using 3D bioprinted implants, including large bone defects and osteochondral defects. The talk will conclude by describing how we can integrate biomaterials and MSCs into 3D bioprinting systems to engineer scaled-up tissues that could potentially be used to regenerate entire diseased joints.
Mussel-inspired adhesives, coatings and films for biological applications
D. Ruiz-Molina

Catalan Institute of Nanoscience and Nanotechnology (ICN2), CSIC and BIST, Campus UAB, Bellaterra, 08193 Barcelona, Spain

Inspired by the wet adhesion of mussels to almost any kind of surface, one of the most widespread methodologies used over the last years to control biocompatibility of surfaces has been the melanin-like oxidative polymerization of dopamine into a polydopamine (PDA), followed by its functionalization with appropriate functional groups. Though, despite its versatility and simplicity, PDA modification relies on the existence of a sufficient amount of reactive groups in the primer coating, which cannot be accurately controlled and, because of PDA insolubility, restricted to in situ polymerization methodologies. Recently, we have reported the development of an alternative, simpler approach to fabricate catechol-based materials with interesting adhesive properties. In this novel strategy, a single monomer bearing both a catechol ring and at least one desired functional side chain (i.e., designed to carry a maximum amount of functional groups) is first synthesized and then polymerized by means of a simple and inexpensive procedure consisting of treatment with ammonia in aerobic conditions. Compared to PDA, the main differences would be, first, the nitrogen source - which is endogenous in the case of catecholamines and external in our case (ammonia) - and, more importantly, the fact that this novel approach does not rely on uncontrolled residual reactivity in order to introduce a specific functionality in the coating because it is already built in the catecholic monomer. Following this approach we have fabricated different families of coatings and nanoparticless of applicability as biosurfaces, theransotics carriers and tissue engineering.

Figure 1: Schematic representation of the bioinspired approach followed for the development of mussel-inspired biomaterials.

Imaging cardiac regeneration
D. Stuckey
Presenting Author: Daniel Stuckey, d.stuckey@ucl.ac.uk
Centre for Advanced Biomedical Imaging, University College London, London, UK

Imaging has the potential to provide robust tools essential for the smooth translation of promising preclinical studies into effective treatments for heart disease. The possibility of visualising location and extent of therapeutic cell retention and correlating this with local and global measures of cardiac structure, function and viability is tantalising. Yet the majority of preclinical and clinical trials still use the simplest of non-invasive methods for monitoring response to treatment; and despite the development of numerous elegant methods for stem cell tracking, few have been applied clinically, and none in recent years for heart disease. This presentation will discuss the strengths and weakness of current imaging approaches adopted in trials of cardiac cell therapy, and will suggest potential future directions which may allow imaging to save cardiac regeneration before it becomes lost in translation.
Viable and cell-free tissue substitutes from human pluripotent stem cells for bone regeneration during aging

D. Marolt1,2

1Ludwig Boltzmann Institute for Experimental and Clinical Traumatology/AUVA Research Center, Vienna, Austria 2The Austrian Cluster for Tissue Regeneration, Vienna, Austria

Regeneration of bone defects in the elderly patients presents significant clinical and scientific challenges, due to the compromised tissue physiology, decreased function of cells driving tissue regeneration and changes in the systemic environment due to aging and diseases. We have previously reported on engineering of bone tissue substitutes from human induced pluripotent stem cells (hiPSCs) [1], which represent an autologous source of potentially rejuvenated tissue progenitors of any lineage and can be prepared for any patient in unlimited quantities [2]. hiPSC-engineered bone substitutes exhibited stability, continued maturation and vascularization in a subcutaneous transplantation model after 12 weeks, suggesting their potential for bone regeneration. Nevertheless, the development and clinical translation of viable hiPSC-based tissue substitutes present significant challenges, with numerous scientific, safety and regulatory questions to be addressed. On the other hand, hiPSCs and their rejuvenated progeny also represent an unlimited resource for the production of secreted factors, vesicles and extracellular matrix that could be employed in cell-free bone tissue engineering strategies. In our current projects, we prepared and characterized these microenvironment components secreted by the hiPSC-derived mesenchymal progenitors (hiPSC-MPs). We identified major cytokine and growth factor components of the hiPSC-MP conditioned media (CM) and separated the extracellular vesicle fractions. We also developed protocols for in vitro engineering of extracellular matrices (ECM) and evaluated their structure/composition before and after decellularization. Using a library of primary bone marrow stromal cells (BMSCs) from traumatology patients of different ages, exhibiting diverse proliferation and differentiation potentials, we found that hiPSC-MP-derived CM and ECM modulate the primary BMSC osteogenic responses in a patient-, dose- and time-specific manner. In particular, some aged BMSC lines only exhibited significant proliferation and osteogenic differentiation when cultured in the presence of hiPSC-MP secreted components. These results suggest that hiPSC-MP-derived microenvironment components can modulate, i.e. “rejuvenate”, the regenerative potential of adult/aged BMSCs. Further investigation into the mechanisms responsible for patient-specific responses and approaches for the engineering of bone tissue substitutes to enhance the regenerative responses in elderly patients will be discussed.

Melt electrospun written scaffolds with optimised fibrous and mineral architectures to enhance human MSC osteogenesis for bone regeneration
D.A Hoey1,2,3,4

Presenting Author: David Hoey, dahoey@tcd.ie
1Dept. Mechanical, Aeronautical and Biomedical Engineering, Materials and Surface Science Institute, University of Limerick, Limerick, Ireland 2Trinity Centre for Bioengineering, Trinity Biomedical Sciences Institute, Trinity College Dublin, Ireland 3Dept. of Mechanical and Manufacturing Engineering, School of Engineering, Trinity College Dublin, Ireland 4Advanced Materials and Bioengineering Research Centre, Trinity College Dublin & RCSI

Material micro-architecture and chemistry play pivotal roles in driving stem cell behaviour. Bone at a cellular level consists of arranged fibres with a cross-fibrillar mineral phase made up of curved nano-sized needle shaped crystals [1]. This nano-structured mineral architecture can bind and stabilise proteins within bone for centuries and thus holds promise as a strategy for therapeutic delivery in regenerative medicine [2]. Herein, we use melt electrowriting (MEW) technology to create fibrous 3D Polycaprolactone (PCL) micro-architectures [3]. These scaffolds were further modified with an extrafibrillar coating of plate shaped micron-sized calcium phosphate crystals (pHA), or with a novel extrafibrillar coating of needle shaped nano-sized crystals (nnHA). A third scaffold was developed whereby nano-sized crystals were placed intrafibrillarly during the MEW process (iHA). Along with vastly differing surface topographies, surface chemistry is altered, with calcium/phosphate ratios differing between groups with values between 1.66 – 1.97, within the range seen in native bone. X-ray diffraction revealed altered crystal structure and crystallinity between groups, with hydroxyapatite (HA) present in all modifications in addition to other minor phases in the extrafibrillar scaffold groups. Water contact angle was investigated revealing increased hydrophilicity with extrafibrillar coatings, while tensile testing revealed enhanced stiffness in scaffolds fabricated with intrafibrillar HA. Biological characterisation demonstrated significantly enhanced human mesenchymal stem cell mineralisation with extrafibrillar coatings, with a 5-fold increase in mineral deposition with plate like structures and a 14-fold increase with a needle topography, demonstrating the importance of bone mimetic architectures. Given the protein stabilising properties of mineral, these materials were further functionalised with BMP2. Extrafibrillar coatings of nano-needles facilitated a controlled release of BMP-2 from the scaffold which further enhanced mineral deposition by stem cells. This study thus outlines a method for fabricating scaffolds with precise fibrous micro-architectures and bone mimetic nano-needle HA extrafibrillar coatings which significantly enhance MSC osteogenesis and therapeutic delivery and thus hold great promise for bone tissue regeneration.

Fabrication of stimuli responsive hydrogel microenvironments for cell manipulation
D. Eglin
Presenting Author: D. Eglin, david.eglin@aofoundation.org
AO Research Institute Davos, Clavadelerstrasse 8, 7270 Davos Platz, Switzerland

Stimuli responsive hydrogels are being developed for use as two and three-dimensional extracellular microenvironments to mimic the features of the extracellular matrices (ECM), for basic and translational studies. The polymers developed for such application can be biopolymer-derivatives showing responsivity to environmental factors such as temperature, enzyme and light. These external stimuli control the polymeric network formation and in fine the ECM-like environment. However, there is often a lack of understanding on how the external stimuli and crosslinking mechanism of these derivatives can influence the cells behavior. In addition, anisotropy in ECM mimic matrices are seldom achieved in controlled manner and in a cell compatible way. Enhance, we investigated the role of hydrogel enzymatic and light crosslinking and of anisotropy fabrication on the behavior of embedded cells.
Materials and growth factors for rotator cuff repair
D. Musson¹
Presenting Author: David Musson, d.musson@auckland.ac.nz
¹Bone & Joint Research Group, Department of Medicine, University of Auckland, New Zealand

Surgical repair of rotator cuff tears have high failure rates (20-70%), often due to a lack of biological healing. Augmenting repairs with extracellular matrix-based scaffolds is a common option for surgeons, although to date, no commercially available product has proven to be effective. As such, there has been great interest in developing novel biomaterials and/or growth factor treatments to help solve this debilitating clinical problem. Over the past 7 years we have worked with orthopaedic surgeons, and chemical and material engineers, in an attempt to identify augments that would significantly enhance healing outcomes for patients undergoing rotator cuff surgery. In vitro studies include assessing primary human tenocyte cell growth, matrix production and the expression of genes important in tendon health and disease, as well as in vitro immune response based on pre-macrophage-like cell activation. If an augment appears promising in vitro, we then assess it in a pre-clinical rat rotator cuff defect model. In the search for the ideal augment, we have assessed synthetic and natural materials designed to be used as overlay augments, aimed at providing both mechanical and biological support. While many have fallen at the in vitro stage, the most promising of these have included a decellularised ovine forestomach matrix, and a pure bovine type I collagen matrix. Both these materials enhanced histological outcomes of the tendon itself, but did not enhance the mechanical integrity of the repair to a clinically significant degree. Based on these findings we hypothesised that in order to improve clinical outcomes, an augment needs to address the healing of the tendon, and the tendon-bone junction. Therefore, materials that are designed to be used as overlay augments may not be the best approach to achieve this. Here, we will discuss our assessment of novel rotator cuff augments, and the findings that have led to our recent hypothesis. Finally we will discuss the application of combination therapies which we feel will have minimal impact on the current surgical procedure of orthopaedic surgeons, but have maximum impact on rotator cuff healing outcomes.

Skeletal vascularized organoids from patient-derived cells
D. Gawlitta1,2
Presenting Author: Debby Gawlitta, d.gawlitta@umcutrecht.nl
1Dept. of Oral and Maxillofacial Surgery & Special Dental Care, University Medical Center Utrecht, Utrecht University, Utrecht, the Netherlands 2Regenerative Medicine Center Utrecht, Utrecht, the Netherlands

Despite the impressive regenerative capacity of bone tissue, large defects cannot heal without intervention. For example, patients suffering from large maxillofacial bone defects receive autologous vascularized bone flap transplants, harvested from a second surgical site, such as the fibula. Bone regenerative strategies could eliminate the need for autologous bone harvesting. Creation of clinically relevant size bone tissue necessitates the co-engineering of a perfused, intricate vascular network to support cell survival in the construct interior. Such skeletal vascularized organoids can be built with various stem cells and/or biomaterials [e.g. 1]. Typically, co-cultures consist of endothelial or endothelial progenitor cells with fibroblasts, osteoblasts, pericytes or multipotent mesenchymal stromal cells (MSCs). To move to patient-specific tissues, autologous stem/progenitor cell sources can be exploited. Both, for patient-specific disease modeling and for implantation in bone defects of patients, these engineered tissues can be relevant. This talk will highlight our approaches to engineer bone organoids containing capillary-like networks from clinically relevant cell sources. In this, the impact of donor variation on the quality of the in vitro formed networks is discussed. Several biomaterials can support the co-formation of these tissues. Furthermore, the establishment of interconnection of multi-scale vascular networks in engineered bone constructs will be demonstrated [2]. This will pave the way for bringing engineered pre-vascularized bone constructs to cm-scale, with in vitro perfusable endothelial networks.

Translation of basic tendon science into clinical practice
D. Docheva
Presenting Author: Denitsa Docheva, denitsa.docheva@ukr.de
Laboratory of Experimental Trauma Surgery, Department of Trauma Surgery, University Regensburg Medical Centre, Regensburg, Germany

Tendons and ligaments are fascinating in their simplistic appearance of tissue architecture coupled with outstanding biomechanical properties. They are also the biggest compartment of our musculoskeletal system and multicentre research in the last decade has led to improved understanding of how these tissues develop, become diseased and do repair. Resident tendon stem progenitor cells (TSPC) have become a central player in tendon science as they exert important functions in tendon formation, physiology and pathophysiology. Here, I will provide evidence from our basic research on: (i) genes regulating certain TSPC features; (ii) the link between TSPC abnormalities and age-related tendinopathy; and (iii) TSPC therapeutic potential. Lastly, in order to effectively translate the novel findings from basic science to clinical practice, I will discuss what further exploratory efforts are required and how to avoid “lost in translation”.

Product development in an GMP manufacturing environment
D.P. Link¹
Presenting Author: Dennis Link, dennis.link@bioconnection.eu
¹BioConnection, Oss, The Netherlands

Everybody has great product ideas, but yet only a small percentage of ideas ever get started. The idea of introducing a product into the market seems overwhelming, complicated and very expensive to most people. They don’t know where to start or what to do, so eventually nothing will be done. That is quite a shame, so this presentation should encourage scientists to build this bridge to industry and develop their ideas into successful products. Before you can actually use your product in a clinical setting you need to manufacture it in an controlled environment. This production method, called Good Manufacturing Practice, is therefore a requirement for the production of medicinal products for the human and veterinary pharmaceutical industry. The quality of medicinal products can never be completely determined by analyzing the composition. Not all possible impurities can be detected and not every product can be analyzed. The quality can therefore only be guaranteed if the entire production process is also carried out in a precise and controlled manner. Within GMP, it is important that it is accurately recorded how and under which circumstances a product is made. During production, all raw materials, intermediates and end products are checked and the process is precisely kept on the so-called preparation protocol. If afterwards something turns out to be wrong with a certain batch of medicines, one can always find out how it was made, who tested it, where and what raw materials were used. Examples of products being developed from the lab bench leading to eventual clinical productions will be shared and risks in product development in a GMP manufacturing environment will be discussed.
(Bio)engineered organs for blood detoxification
D. Stamatialis
Presenting Author: Dimitrios Stamatialis, e-mail: d.stamatialis@utwente.nl
(Bio)artificial Organs, University of Twente, TechMed Institute of Biomedical Technology and Technical Medicine, Faculty of Science and Technology, P.O Box 217, 7500 AE Enschede, The Netherlands

For patients with chronic kidney disease the best solution would be organ transplantation. However, due to shortage in donor organs and the fact that not all patients are eligible for transplantation, most patients are currently treated with therapies using artificial kidney devices. In hemodialysis therapy, a widely available and well-established treatment for the patients with End Stage Renal Disease, the blood of these patients is cleansed 3-4 times a week in dedicated dialysis centres. Major drawbacks of the therapy are the poor removal of middle-sized molecules and protein-bound uremic solutes and the non-continuous treatment, causing large fluctuations in water balance and uremic wastes of the patients. Besides, the need for continuous visits at the dialysis centres is a great social and psychological burden for these patients. In this talk we will discuss bioengineered concepts for achieving better and more continuous removal of a broad range of uremic solutes and for mimicking better the kidney function, including the concept of: Mixed matrix membranes (MMM) which combine the benefits of diffusion and/or convection, provided by the membrane structure, and of adsorption, achieved by sorbent particles dispersed in the membrane; Bioartificial kidney where “living membranes” of tight renal cells monolayer with preserved functional organic ion transporters attached on suitable artificial membranes, can actively remove the uremic solutes mimicking the function of the kidney proximal tubule.
A gel-based model of selective cell motility: Implications for cell sorting, diagnostics and screening
D. Seliktar
Presenting Author: Dror Seliktar, dror@bm.technion.ac.il
Faculty of Biomedical Engineering, Technion – Israel Institute of Technology, Israel

The ability to precisely control cell-loaded material systems is essential for in vitro testing of novel therapeutics poised to advance to clinic. In this report, unique patterns of cell migration by chemotaxis were devised into an in vitro gel-in-gel model for the purpose of obtaining cell response data to potentially therapeutic agonists. The model consisted of co-cultures in a cell-loaded microgel invading an acellular “sorting” gel. Material properties including biophysical and chemical composition of the sorting gel were carefully controlled to guide a desired cell-specific behavior, leading to massive tumor cell invasion by amoeboid migration mechanisms. Optical transparency enabled straightforward and high-throughput measurements of outgrowth response in the presence of either chemical and photo-radiation therapy. Important dosing and drug sensitivity information were obtained with the gel-in-gel model using no more than a light microscope, without further need for arduous genomic or proteomic screening of the tissue samples.
Bioprinting scaffold-free constructs with cell-only bioink
E. Alsberg¹²
Presenting Author: Eben Alsberg, ealsberg@uic.edu
¹Departments of Bioengineering and Orthopaedics, The University of Illinois, Chicago, IL, USA
²Departments of Biomedical Engineering and Orthopaedic Surgery, Case Western Reserve University, Cleveland, OH, USA

Three-dimensional (3D) bioprinting has been pursued to build scaffold-free tissue constructs presenting functionally and sophisticated geometry without the presence of an intervening scaffold that can interfere with critical cell-cell interactions. However, to date it has not been possible to print individual cells directly, as preculturing was required to first form cell aggregates or strands prior to printing.¹ Here, the first bioprinting platform using single cells alone, without a macromer solution, as an ink will be reported. A shear-thinning and self-healing support bath permits high-resolution printing of the ink into precise geometries, maintenance of cell viability, cellular condensation formation and long-term culture of constructs for development of engineered tissues. Collectively, the platform may advance cellular condensation-based regenerative medicine strategies, enhance drug-screening capabilities and provide a new tool for addressing questions in developmental biology.

Cellular brain repair for Parkinson’s disease: Is the answer in the (biomaterial) matrix?
E. Dowd¹,²
Presenting Author: Eilís Dowd eilis.dowd@nuigalway.ie
¹Pharmacology & Therapeutics and ²Galway Neuroscience Centre, National University of Ireland Galway (NUI Galway), Galway, Ireland

Cell-based brain repair is a promising option for Parkinson’s disease (PD) whereby the nigrostriatal dopaminergic neurons that have degenerated over the course of the disease are replaced by transplantation of healthy neurons into the brain. Given that cell-based brain repair is rapidly accelerating towards the clinic, with the ongoing TRANSEURO trial of fetal tissue and the recently announced Takahashi trial of iPSC-derived dopaminergic neurons in Japan, but that the margin for improvement of such approaches is great, it is critical to continue rigorous preclinical studies to identify potential methods of improving the outcome of cell-based brain repair for patients. In this context, we will be presenting our recent data demonstrating that dopaminergic cell replacement in the Parkinsonian rodent brain, using fetal-derived cells, is dramatically enhanced when the cells were transplanted in a neurotrophin-enriched, immune-shielding collagen hydrogel [1-3]. The hydrogel provided the transplanted neurons with 1) a physical scaffold for cell-matrix adhesion, 2) a neurotrophin reservoir for sustained neurotrophin exposure after transplantation, and 3) shielding from the deleterious effects of the host microglial and astroglial innate immune response (Fig. 1). We will also present data from studies encapsulating human iPSC-derived dopaminergic neurons. Overall, this work suggests that the clinical transplant field should move towards the incorporation of biomaterials, such as neurotrophin-enriched collagen hydrogels, into future clinical trials using primary and/or iPSC derived neurons. Improving the safety and efficacy of such approaches, using this minimally invasive and injectable hydrogel that offers a neuroprotective and immune shielding microenvironment to the transplanted cells, could dramatically improve the reparative capacity of cell therapy for PD, and ultimately lead to an improved therapy for patients.

Figure 1: Impact of the neurotrophin-enriched collagen hydrogel on dopaminergic transplants.

A novel integrated low cost tool for accelerating therapies for pancreatic cancer from bench to bed
E.G. Velliou
Presenting Author: Eirini G. Velliou, e.velliou@surrey.ac.uk
Bioprocess and Biochemical Engineering Group (BioProChem), Department of Chemical and Process Engineering, Faculty of Engineering and Physical Sciences, University of Surrey, Guildford, Surrey, UK

Pancreatic Ductal Adenocarcinoma is a deadly disease with 91% of patients dying within five years from diagnosis. This disheartening figure has barely been improved the last 50 years. The low survival rate of patients with pancreatic cancer is partly due to the tumour resistance to currently available treatment, which results from the complex and highly heterogeneous tumour microenvironment (TME). The TME is the biological, biochemical and biomechanical environment that surrounds the tumour and interacts with it in various complex ways, consequently affecting the tumour progression and response to treatment. A key challenge in cancer tissue engineering is ensuring accurate mimicry of the multiple key features of the TME. Our goal is to address this challenge via the development of a high-fidelity animal free pancreatic cancer model, which will enable patient specific treatment optimisation. We use as a basis our developed highly porous polymeric scaffolding system which we advance biochemically and biologically to mimic crucial TME features. More specifically, we create a tri-culture of pancreatic tumour cells, pancreatic stellate cells and endothelial cells. With surface modification of the scaffold we enable coating with various extracellular matrix protein (ECM) compositions and by immersing the scaffold in a 3D printed perfusion bioreactor we achieve mimicry of the blood flow. The versatility of the synthetic scaffold allows to recapitulate and test multiple critical aspects of the pancreatic TME including cell-cell and cell-ECM interactions, stiffness, tissue porosity, diffusion of oxygen, nutrients, metabolites and distribution of the vascularization. Herein, key advancements of our platform will be discussed.
Biomimetic scaffolds for soft tissue engineering via melt electrowriting
E.M. De-Juan-Pardo1,2
Presenting Author: Elena M. De-Juan-Pardo, elena.juanpardo@qut.edu.au
1Centre in Regenerative Medicine, Institute of Health and Biomedical Innovation (IHBI), Queensland University of Technology (QUT), Brisbane, Australia 2School of Chemistry, Physics and Mechanical Engineering (CPME), Science and Engineering Faculty (SEF), Queensland University of Technology (QUT), Brisbane, Australia

Melt electrowriting (MEW) is an emerging additive biomanufacturing technique capable of printing fibrous constructs in ultra-high resolution, bringing down the jet diameter to the micrometre-to-nanometre scale. Scaffolds manufactured by MEW are tailorable in terms of fibre architecture, porosity and thickness [1]. Moreover, MEW is a solvent-free process, compatible with the use of medical grade thermoplastic polymers. These exclusive advantages make MEW an ideal manufacturing technique for the production of scaffolds for a wide range of biomedical applications. However, despite the great benefits of MEW, this technique is still at its infancy in a few laboratory set-ups. This work explores the potential of MEW for soft tissue engineering. There is a great need to develop novel biomaterials capable of recapitulating the complex biomechanical features of soft tissues. Native soft tissues are characterised by a strain-stiffening behaviour that makes them very sensitive to load. Herein, the unique capabilities of MEW to produce biomimetic scaffolds with controlled non-linearity, strain-stiffening behaviour, anisotropy and viscoelasticity for soft tissue engineering is presented. This is achieved by applying a biomimetic design approach inspired in the wavy architecture of the collagen fibres present in soft tissues and their load-dependent recruitment. In summary, MEW is an exceptional additive biomanufacturing technique which enables the manufacture of complex biomimetic materials for soft tissue engineering.

Figure 1: MEW scaffolds present J-shaped stress-strain behavior under tensile load, similar to native soft tissues such as skin. Image reprinted with permission from [3]. ©2017 American Chemical Society.

Label free optical bioimaging for stem cells research
E.V. Zagaynova

Presenting Author: Elena Zagaynova, ezagaynova@gmail.com
1Institute of Biomedical Technologies Privolzhsky Research Medical University, Nizhny Novgorod, Russia

The promising task in the pre-clinical and clinical testing of the bioengineering constructs and the biomedical cellular products is using multimodal label free imaging. Such unique techniques allow to visualize the individual cells embedded in the constructs, their migration, proliferation, and also to study the cell differentiation processes. The study of the epigenetic mechanisms of stem cell (mesenchymal stromal cells (MSC), induced pluripotent stem cells (iPS)) differentiation is an actual problem. So, using fluorescence lifetime imaging microscopy (FLIM) the metabolic switch from glycolysis to oxidative phosphorylation was shown during MSC and iPS differentiations by the lifetimes changing of NAD(P)H [1]. Also, we studied the involvement of seeded allogeneic MSCs in bone formation using the model of transgenic mice expressing fluorescent protein GFP and genetically labeled cells [2]. Despite the significant progress in developing of skin equivalents (SEs) a problem of non-invasively assessing the quality of the cell components and the collagen structure of living SEs both before and after transplantation remains. Using the methods of optical coherence tomography (OCT), multiphoton tomography (MPT) and FLIM, the structure and quality of dermal SEs before transplantation, and remodeling of collagen matrix and microcirculation in the wound healing after dermal SEs transplantation were studied [3].

One major approach to regenerative medicine has focused on decellularized tissues and whole organs. Another approach that is getting interest are the cell-derived extracellular matrices (CDMs). These CDMs can be produced using extracellular matrix (ECM) substrates, cell pellets, scaffolds (like hydrogels, microcarriers or 3D printed structures) and scaffold-free living cell sheet culture systems. Alternatively to decellularized tissues, these CDMs can mimic some aspects of the native tissue microenvironment due to its complex composition and the existing possibility to tailor-made them by selecting different production parameters such as cell types and stirred 3D culture among others. This allows to produce patient specific models and disease to understand disease mechanism and test drugs. In this study we will show the production of these CDMs and how they can be used as scaffolds for regenerative therapies.
Laser surface engineering of biomaterials for neural tissue engineering applications
E. I. Stratakis
Presenting Author: Emmanuel I. Stratakis, stratak@iesl.forth.gr
Institute of Electronic Structure and Laser, Foundation for Research & Technology Hellas, Heraklion Greece

The surface topography of biomaterials can have an important impact on the cellular adhesion, growth and proliferation. Apart from the overall roughness, the detailed morphological features at all length scales, significantly affect the cell-biomaterial interactions in a plethora of applications including structural implants, tissue engineering scaffolds and biosensors. We present a simple, one-step direct laser patterning technique to fabricate various types of micro/nano structured biomaterials platforms. Variation of the laser fluence, alters the surface morphology, leading to a rippled-type, at lower laser fluences, or a conical spiked-type morphology, as the laser fluence increases. Hierarchically-structured cell culture platforms incorporating gold nanoparticles functionalized with specific bio-functional moieties have been additionally developed. Cells with nerve cell phenotype were cultured on the substrates. More specifically, PC12 cells cultured on the developed substrates and treated with nerve growth factor showed a differentiation response that was highly dependent on the surface topography. While, experiments with DRG/SCG nerve cells showed a differential orientation of the cells, depending of the underlying geometry of the laser engineered surface structures. Finally, depending on the laser processing conditions, distinct SW10 cell-philic or cell-repellent patterned areas can be attained with a desired motif, enabling spatial patterning of cells in a controllable manner. Our work provides a versatile method to tune neuron cell responses by proper selection of the surface free energy of the substrate and may be promising for the design of cell culture biomaterial platforms with controlled differentiation environment.
Optimising medical device tissue adhesion and integration through mechanical and surface topographical methods

E.D. O’Cearbhaill

The interface between host and implant is a key predictor of device performance. When seeking to attach or integrate medical devices with host soft tissue, current methods of fixation can lead to suboptimal results. There is a reliance on (1) chemical-based adhesives, which require tissue-specific reactive chemistry and subsequent risk of an inflammatory response, or (2) mechanical methods of fixation (sutures or staples) which can induce significant local tissue damage and associated increased risk of infection. Here, we present two examples of novel interfacing geometries optimised for tissue adhesion and integration respectively. Firstly, a novel two component angled-microneedle patch design is described, which achieves robust and reversible mechanical adhesion to skin (4-5 times the mechanical adhesive strength of cyanoacrylate). This creates a stable platform for ‘click-on’ drug delivery and biosignal sensing applications, where sensors can be subsequently removed with near-zero force through the reverse mechanical action or designed to bioresorb. Secondly, utilising a novel additive manufacturing approach, we produce soft flexible silicone-based implants with a unique surface topography designed to minimise fibrosis and control the wound-healing response. These geometrical conformations create platforms for optimal tissue fixation and integration for a broad range of medical devices.
Bio-engineering human skin: The long way from basic research to clinical trials

E. Reichmann1,2

1Tissue Biology Research Unit (TBRU), University-Children’s Hospital, Zurich, Switzerland
2University of Zurich, Switzerland

New, substantial and clinically applicable achievements in skin replacement and regeneration are rare. The most significant steps forward within the past 45 years have been the development of Cultured Epidermal Autographs (CEA) by the method of Rheinwald and Green (1975) and the invention of the Integra™ Dermal Regeneration Template, by Joannis V. Yannas and John F. Burke in 1981. The Tissue Biology Research Unit (TBRU) in Zurich, Switzerland has more recently come up with several novel bio-engineered skin equivalents, one of which is named DenovoSkin™. DenovoSkin™ is a collagen-hydrogel based, dermo-epidermal skin graft, containing (autologous) fibroblasts in its dermal compartment and (autologous) keratinocytes in its epidermal compartment. To date DenovoSkin™ is presumably the most complex autologous bio-engineered product applied in the clinic. DenovoSkin™ was successfully tested in a Phase I study [1] and is presently used in a prospective, intrapersonally-randomised, interventional, multicentrical Phase II study. In addition DenovoSkin™ is presently applied in compassionate use on a severely injured pediatric burn patient. DenovoSkin™ received the Orphan Drug Designation (ODD) for the treatment of burns from Swissmedic, the EMA and the FDA respectively. On the basic research level the TBRU has developed dermo-epidermal skin equivalents [2-3] exhibiting properties of full thickness human skin, which is a) pre-vascularized by a capillary plexus, and b) pre-pigmented by a functional melanocyte compartment. The TBRU is presently translating this new generation of bio-engineered skin equivalent into GMP-production and clinical application.

Aging of the skeletal muscle extracellular matrix and its effect on stem cell functionality
F. Ambrosio 1,2
Presenting Author: Fabrisia Ambrosio, ambrosiof@upmc.edu
1Rehabilitation for UPMC International 2Department of Physical Medicine & Rehabilitation, University of Pittsburgh School of Medicine, U.S.A.

Skeletal muscle trauma resulting from an injury or surgery often results in significant functional declines in older adults. These declines are at least partially attributed to failed muscle healing. Muscle regeneration is predominantly dictated by the action of muscle stem, or “satellite”, cells (MuSCs), a reserve cell population that typically demonstrates considerable dysfunction with increasing age. According to the stem cell “niche” concept, stem cell responses are largely determined by biophysical and biochemical cues that emanate from the surrounding microenvironment. Indeed, expanding recognition of the influence of the microenvironment on stem cell behavior has led to a recent surge in the development of bioinspired and engineered extracellular matrix (ECM) approaches for the treatment of skeletal muscle injuries. Still lacking, however, is an in-depth knowledge of whether and how pathogenic instructional characteristics of the native ECM disrupt MuSC function and skeletal muscle regeneration. While it is evident that MuSC activation, self-renewal, proliferation and differentiation are influenced by physical and dynamic niche interactions, a mechanistic understanding of the direct impact of age-related ECM alterations on skeletal muscle regenerative capacity is unknown. In her presentation, Dr. Fabrisia Ambrosio will share recent in vitro, ex vivo and in vivo data from her laboratory demonstrating that that age-related biophysical alterations in the skeletal muscle ECM promotes a fibrogenic conversion in MuSCs, ultimately driving impaired skeletal muscle regeneration.
Towards an artificial meniscus: Biomechanical properties as a driver for orthopaedic innovation
F. Barberis1,2
Presenting Author: Fabrizio Barberis, fabrizio.barberis@unige.it
1Department of Civil, Chemical and Environmental Engineering - (DICCA), University of Genoa, Italy 2Genova Additive Manufacturing – (GeAM), Genova, Italy

Meniscal tear is still an unsolved problem in regenerative medicine. The almost total inability in self-healing damaged tissue shown by the menisci is due to the extremely reduced amount of vessels for blood supply that does not allow the normal inflammatory response promoter of tissue healing. The use of cadaveric meniscal allografts is subject to several inconveniences as penury of donor tissue, risk of infections and size matching. The challenge is therefore oriented towards the artificial meniscus prostheses. The use of composites based polymeric materials could partially replicate the complex internal structure determined by differently oriented layers operating in a fluid environment. In order to obtain a mechanically efficient prostheses it is indeed fundamental to deeply study the mechanical characteristics of the natural meniscus tissue preserving the features and behaviour of the original structure. A different, non destructive, method able to measure the effective mechanical response of a natural meniscus in its different regions without affecting the results by the sampling inconvenience was set up and described in this work. This technique let to combine a sequent set of classical destructive tests on the same menisci samples, providing an innovative database of mechanical data able to support the projecting phase of a new artificial meniscus.

Osteoarthritis (OA) is the most common form of inflammatory, degenerative and painful joint disorder affecting the whole joint tissues including the articular cartilage and bone. Despite the increase of OA incidence, there is still no effective therapy able to restore the structure and function of injured articular cartilage. In this context, mesenchymal stem cell (MSC)-based therapies for OA have become thriving areas of research. MSC have been tested in preclinical studies with results highly predictive of clinical success. Thereby, for a decade, MSC have been the subject of many clinical trials in OA demonstrating their safety and efficacy in phase I and II trials and promising results in phase III trials [1, 2]. Tissue repair potential of MSC relies mainly on their paracrine activity mediated through the release of various trophic factors able to enhance tissue repair by regulating the inflammatory response, stimulating endogenous cells and protect tissues from further degradation. More recently, extracellular vesicles (EV), pivotal mediators of cell-to-cell communications, have been shown to be secreted by MSC and to recapitulate their functions. Our laboratory has studied, in vitro, the anti-inflammatory, anti-apoptotic and chondro-protective properties of MSC-derived EV [3]. The data obtained will be discussed as well as the current knowledge on the effects of EV derived from MSC in experimental models of inflammatory or degenerative joint disorders.

Scaffold-based delivery of nanomedicines for bone and cartilage repair
F.J. O’Brien1,2,3
Presenting Author: Fergal J. O’Brien, fjobrien@rcsi.ie
1Tissue Engineering Research Group, Dept. of Anatomy, Royal College of Surgeons in Ireland (RCSI), Dublin, Ireland 2Trinity Centre of BioEngineering, Trinity College Dublin (TCD), Ireland 3Advanced Materials and Bioengineering Research Centre (AMBER), RCSI and TCD, Dublin, Ireland

Developing a biomaterials-based solution for the repair of large scale damage to the articular joint presents a particularly complex challenge due to the complex zonal structure of osteochondral tissue, the issues combining weightbearing with any treatment, and the challenges in directing regenerative stem cells to promote the formation of non-hypertrophic stable hyaline cartilage. Ongoing research in our lab is focussed on the application of multi-layered biomimetic natural polymer-based 3D porous scaffolds for the repair of bone and cartilage in articular joints [1]. Increasingly we are utilising 3D printing to produce such materials with enhanced mechanical properties to facilitate weight bearing. Furthermore, we have been focussing on functionalising these scaffolds for use as delivery systems for biomolecules such as therapeutic nanomedicines enhance their therapeutic potential. These gene activated scaffold platforms thus act as both a template for cell infiltration and tissue formation while also directing autologous host cells to engineer therapeutic proteins in a sustained but eventually transient fashion [2]. Similarly, we have been utilising scaffold-mediated delivery of siRNAs and miRNAs [3] to silence specific genes associated with aberrant effects in bone and cartilage repair. This presentation will highlight some of the particular problems with developing viable clinical treatments to prevent or delay the need for joint replacement and will provide an overview of ongoing research in our lab on gene-activated biomaterials for bone and cartilage repair.

ACKNOWLEDGEMENTS: Financial support from Science Foundation Ireland, Health Research Board and the European Research Council.

REFERENCES
Extracellular vesicles (EVs) are recognized as the nature's own carriers to transport macromolecules throughout the body. Hijacking this endogenous communication system represents an attractive strategy for advanced drug delivery. However, efficient and reproducible loading of EVs with therapeutic or imaging agents as well as high yield cost-effective manufacturing of EVs still represents bottlenecks on the road towards the use of EVs as the next-generation drug delivery system (DDS).[1] To enable clinical translation of EV-based therapy, our group is developing disruptive technologies for large scale, high yield production and engineering of EVs. We will present technological breakthroughs which enable – i) to produce EVs at high yield and high throughput in scalable and GMP-compliant bioreactors based on turbulence stimulation on any producer cells, -(ii) to load EVs with internal or membrane cargoes (inorganic nanoparticles, hydrophilic and hydrophobic drugs…) to endow them with new properties, -(iii) to achieve image-guided photodynamic therapy (PDT) using EVs in a peritoneal carcinomatosis model. 

**EV production:** Pursuing the analogy with shear-stress induced EV release in blood, we are developing mechanical stress triggering approaches to induce fast EV generation. First proof of concept was done in a microfluidic device allowing fast generation of EVs.[2] In order to upscale shear-stress induced EV production in a controllable manner, we then propose turbulence as a tunable and effective trigger to generate EV into GMP-compliant bioreactors, with a ten-fold gain both in production time and yield.

**EV engineering.** We propose versatile technologies to engineer EVs with internal or membrane cargoes, relying either on engineering precursor cells (e.g. nanoparticle cellular uptake [3]), or on post-production EV modification. For example, PEG-facilitated fusion of EVs with functionalized liposomes was used to create smart biosynthetic hybrid vector with improved cellular delivery efficiency of a chemotherapeutic compound as compared to the free drug or the drug-loaded liposomes.[4] **Spatio-temporal control of EV therapeutic activity.** Stem cell or endothelial cell-derived EVs loaded with a photosensitizer show favorable biodistribution, safety and enhanced light-induced therapeutic efficiency in 3D tumoroids [5], subcutaneous tumor xenograft and in a mouse model of peritoneal carcinomatosis. Our unique technologies for EV production and engineering combines decisive assets for clinical translation of EV-based DDS.

Osteoconductive microarchitectures for high performance bone substitutes
F.E. Weber
Presenting Author: Franz E. Weber, franz.weber@zzm.uzh.ch
Oral Biotechnology & Bioengineering, University of Zurich, Center of Dental Medicine, Plattenstrasse 11, 8032 Zurich, Switzerland

In the 90ties of the last century, the holy grail of pore size for scaffolds in bone tissue engineering was set between 0.3 and 0.5 mm. These values appeared reasonable since they fall in line with the diameter of osteons and influenced the microarchitectural design of bone substitute thereafter. More recently, two papers indicated that pores even bigger than 0.5 mm perform equally well [1-2]. Therefore, the optimal microarchitecture for bone tissue engineering scaffolds in terms of pore size, constrictions, rod thickness, or rod distance is still elusive. Additive manufacturing appears as an ideal tool to study those diverse microarchitecture options since it can generate scaffolds where size and location of pores and connections between pores can be tested. For the production of scaffolds, we applied for titanium-based scaffolds laser sintering and for ceramics lithography-based additive manufacturing. As in vivo test model, we used a calvarial defect model in rabbits. Histomorphometry revealed that all generatively produced structures were well osseointegrated into the surrounding bone. The histomorphometric analysis, based solely on the middle section, showed that bone formation was significantly increased with pores between 0.7-1.2 mm in diameter. Scaffolds with pores of 1.5 and 1.7 mm perform significantly worse. Therefore, pore diameters in osteoconductive bone substitutes should be 1.0-1.2 mm and thus much bigger than previously suggested [3-5]. For lattice microarchitectures we found rods of 0.3 mm in diameter and 0.8 mm distant to each other highly osteoconductive. In essence, additive manufacturing enabled us to generate libraries of microarchitectures to search for the most osteoconductive microarchitecture. Moreover, additive manufacturing appears as a promising tool for the production of personalized bone tissue engineering scaffolds to be used in cranio-maxillofacial surgery, dentistry, and orthopedics.

BIOCAPAN: an innovative microcapsule-based advanced therapy medicinal product for the treatment of diabetes mellitus type I
F. Bottausci 1
Presenting Author: Frederic Bottausci, frederic.bottausci@cea.fr
1Univ. Grenoble Alpes, CEA, LETI, DTBS, Grenoble, France

Type 1 diabetes (T1D) results from the destruction of insulin-producing Beta-cells by the patient’s overactive immune system [1]. The replacement of these lost insulin-producing cells using islet transplantation has proved to be effective for some T1D patients [2]. The main limitation is the need for life-long immunosuppression to prevent rejection of the transplanted cells. Encapsulating the islets appears to be a promising approach [3] since it offers a physical barrier between the cells and the receiver immune system [1] while being porous enough to allow exchange with blood. The technology used in the frame of the BIOCAPAN project relies on microencapsulation. This process has the advantages of producing monodispersed capsules with a controlled diameter that can be adapted to the islets size. The spherical shape and the reduce thickness of the biomaterials between islets and the environment outside the capsule maximizes the exchanges, limiting the necrosis and promoting oxygen, nutrient supply and insulin secretion. We present a method and apparatus for well-controlled microencapsulation of insulin secreting human islets (Langerhans islets) in a high viscous (up to 10 Pa.s) innovative mix of biopolymers and biological elements. The mix aimed at improving the islets viability without altering the insulin secretion as well making the capsule stealthy to the host immune system. The microencapsulation is performed by an advanced equipment we developed that uses disposable encapsulation-oriented microfluidic cartridges. The system, complying with microfluidic standards, is a GMP (Good Manufacturing Practices)-like equipment allowing a fully automated encapsulation process providing ready-to-implant microcapsules. We will finally show encapsulated islets in the mix of biopolymers and biological elements. Encapsulating islets are then ready to be characterized in vivo and in vitro to validate biocompatibility, viability and functionality. This project has received funding from the European Union’s Horizon 2020 research and innovation program under grant agreement No 646272 (BIOCAPAN).

INTRODUCTION: Islet cell transplantation is a promising treatment for type 1 diabetes mellitus (T1D), but current strategies require immunosuppression and have been plagued by poor islet cell retention and reduced implant viability (1). Technologies to assist the delivery and engraftment of islets in extrahepatic sites are necessary for widespread clinical adoption of islet transplantation. Here we provide an update from Diabetes-Reversing Implants for enhanced Viability and long-term Efficacy (DRIVE), a European Consortium supported by EU Horizon 2020 funding. The objective of DRIVE is to develop a platform for islet cell transplantation that improves cell retention and viability, is delivered in a minimally invasive fashion, and negates the need for systemic immunosuppression.

METHODS: DRIVE partners have developed a multicomponent platform to improve islet cell delivery. Technologies under development include β-Gel, a support matrix for islet cell growth, β-Shell, an immunoprotective macroencapsulation device, and TheraPocket, a procedure for delivering islet cells to a target implant site in the anterior abdominal wall.

RESULTS & DISCUSSION: The β-Gel is a pancreo-mimetic hydrogel with pancreatic extracellular matrix proteins and oxygen producing compounds that provides a support matrix for islets. β-Gel has been tested extensively in vitro and supports human islet cell survival and insulin release. A candidate technology and delivery device suite has been developed for a macroencapsulating β-Shell. β-Shell has been tested to deliver a proangiogenic growth factor and β-Gel in a subcutaneous implant model in rats and pigs. Early results demonstrate robust neovascularization around implants and survival of islets and restoration of glycemic control over 4 weeks in a STZ induced rodent model. Exploratory studies in pigs and cadavers have been used to evaluate possible implant sites in the anterior abdominal wall for development of the TheraPocket procedure. Significant progress has been made in developing DRIVE technologies for improved islet cell transplantation. Preclinical studies to evaluate the therapeutic effectiveness of a clinically scaled and translatable DRIVE platform are ongoing.

Almost anyone who embarks upon a career in science shares similar passions, hopes and beliefs culminating in the desire to solve current problems, discover the unknown and develop beneficial innovative products. It was my passion for research coupled with the desire to continuously extend the frontiers of knowledge whilst enthusing the next generation with a love for what current scientific breakthroughs might hold in the future that drove me to become an academic. The world of academia has now however become more challenging as the once sought-after sector of learning now aligns less with the former ideals of independent blue sky thinking where academics could just get on and undertake research. It now has to concede to a more ‘real world’ outside of the ivory tower where academics constantly have to juggle budget management, grant writing, teaching, marking, publishing and research, all whilst living with the constant fear of non-permanent contracts in a relatively slow-moving environment with regards to innovation and rapid new product deployment. The aim of this presentation is to openly discuss alternative career choices for PhDs, to take an objective and honest look at the odds of achieving a fulfilling academic or industrial career in science and the required professional and personal attributes to do so. Most importantly, based on personal experience, this presentation will also cover an often overlooked third career option- starting your own company as an entrepreneur. The third option is particularly interesting if personal motivators include an entrepreneurial streak, a strong desire to apply scientific discoveries in product development and practical problem solving. This presentation will help provide an insight into how it might be possible to balance a demanding academic career whilst also striving to set up a biotech start-up company on a shoestring budget. The talk will furthermore cover trials and tribulations of academic careers, the different avenues available should you want to venture into the exciting world of entrepreneurism and demonstrate that it is possible to synergise both entrepreneurial and academic ambitions across the perceived division of “academia versus industry”.

Bio-inspired bone adhesive proven to be safe in vivo
G. Insley
Presenting Author: Gerard Insley, gerard@gpbio.net
GPBio Ltd. Rathkeale, Ireland

INTRODUCTION: A new combination of \(\alpha\)-tricalcium phosphate (\(\alpha\)TCP) and calcium silicate cements, modified with phosphoserine, have a proven ability to glue tissues together [1]. The aim of this study was to assess the in vivo safety of this new biomaterial by implantation into subcutaneous pockets, in rats.

METHODS: Precured implants (n=9) with high (45%/28%) and low (25%/2%) concentrations of phosphoserine and calcium silicate, respectively, were implanted subcutaneously in male rats (≈450g) for 6 and 12 weeks. \(\alpha\)TCP discs, without silicate and phosphoserine, were used as controls. The implants were analysed via histology (hematoxylin and eosin) and through gene expression, exploring three immune markers and three bone markers (IL1, IL6, TNF1, COL1A, SOX9, RUNX2) to assess any adverse effects or stimulation on the surrounding soft tissue.

RESULTS & DISCUSSION: The histology assessment revealed no signs of adverse effects at the interface between the cured adhesive formulations and the connective tissue. There were no signs of multinucleated cells, nor fibrotic tissue with unaffected connective tissue layers, shown in figure 1. Gene expression analysis confirmed the histology findings, without any measurable regulation of the selected gene markers. The adhesives did not elicit expression of any of the gene markers, and no differences were observed between the test groups and the control.

CONCLUSIONS: This bio-inspired bone adhesive has been proven to be safe with an absence of any side effects on the surrounding soft tissue. These findings encourage further investigation of the full potential of the adhesive biomaterial in tissue repair models.

Figure 1: Representative images of the adhesive with 45% phosphoserine and 28% silicate, and control TCP, after 6 and 12 weeks. The explants reveal normal tissue without any adverse reactions. The histology sections depicted thin layers of unaffected connective tissue surrounding the implants.

ACKNOWLEDGEMENTS: This work were partly funded by the Swedish Science Foundation (#RMA15-0110) and EIT Health HeadStart grant (2018 HS PoC 2018-HS-0046).

Heterogeneity in adult human mesenchymal stem cells due to origin and culture expansion

G.J.V.M. van Osch
Presenting Author: Gerjo J.V.M. van Osch, g.vanosch@erasmusmc.nl
Erasmus MC, University Medical Center Rotterdam, The Netherlands

Mesenchymal Stem Cells (MSC) are a population of cells that can be obtained from adult tissues and expanded in culture to obtain a large number of cells with multi-lineage differentiation capacity. Thus MSC offer great promise for tissue engineering of many connective tissues. One of the limiting factors of the use of MSC is their heterogeneity. This leads to variable outcomes between patients, labs and experiments. Part of the heterogeneity can be explained by the origin of the MSC. Besides differences caused by harvesting site, different types of MSC are present within one harvest. We have demonstrated differences in chondrogenic capacity between perivascular and lining cells from bone marrow as well as from synovium and have found specific markers to select different populations from the harvested samples. Further heterogeneity is caused by in vitro expansion. Cell expansion is known to cause cellular senescence and loss of differentiation potential. The method of expansion is of large influence and we have found that addition of Wnt3a to the culture medium improves the quality of the MSC. Future research to better understand the heterogeneity of this population of cells and the potential of its subpopulations, will improve the application of MSC in disease model systems and regenerative medicine application and might help us to find methods to stimulate endogenous tissue repair.
Biological polymers as enabling materials for brain tissue model and engineering

G. Ciardelli 1,2,3

Presenting Author: Gianluca Ciardelli, gianluca.ciardelli@polito.it

1Department of Mechanical and Aerospace Engineering, Politecnico di Torino, Turin, Italy 2POLITO BIOMedLAB, Politecnico di Torino, Turin, Italy 3Department for Materials and Devices of the National Research Council, Institute for the Chemical and Physical Processes (CNR-IPCF UOS), Pisa, Italy

Pathologies affecting brain tissue are mainly ascribed to neurodegenerative diseases and central nervous tissue injuries. Neurodegenerative diseases affect more than 100 million individuals worldwide (WHO) causing loss of nerve structure and function and consequently memory loss, change in personality, and dementia. On the other hand, central nervous system injuries, which are mainly related to spinal cord injuries, affect a lower number of patients (approximately 2.5 million people worldwide) but cause enormous functional deficits to patients which lead to disastrous social consequences and huge economic costs. Although intensively studied for over 100 years, no treatment or intervention options are currently available to stop the neurodegenerative pathology progression and to functionally reconnect injured spinal cord. The design of tissue constructs able to recapitulate the complex multicellular environment of brain tissue is a key strategy to model the pathological environment and to progress in treatment efficacy. In this work, biological polymers were applied to engineered an extracellular matrix (ECM)-like environment able to host brain cells of different phenotypes. ECM-like environment can be combined with cells to design advanced therapy medicinal products (ATMPs) to cure pathologies affecting the central nervous system as well as in vitro brain tissue models to study pathologies progression and therapeutic efficacy. Chitosan (CS) was selected as former biomaterial thanks to its well-documented biocompatibility, easy processability, low immunogenicity and anti-inflammatory properties. Several protocols were developed to process CS in form of nanofibers and 3D printable bioinks [1]. Furthermore, gelatin and collagen were combined with CS to achieve a biomimetic ECM-like environment. Additional cues such as antioxidant agents [2], growth factors [3] and cells can be easily loaded within nanofibres and bioinks to better tailor the cell/biological polymer interactions. Physico-chemical properties of the developed nanofibers and bioinks were analysed as well as their ability to allow cell survival of multiple cell populations. By exploiting the biomimetic composition of biological polymers and their tunable properties, the developed 3D ECM-like environment could be applied in the study and treatment of several challenging diseases affecting the central nervous system.

Piezoelectricity applied to tissue engineering: A new approach based on remote cell stimulation
G. Ciofani¹²
Presenting Author: Gianni Ciofani, gianni.ciofani@iit.it
¹Smart Bio-Interfaces, Istituto Italiano di Tecnologia, Pontedera, Italy ²Department of Mechanical and Aerospace Engineering, Politecnico di Torino, Torino, Italy

The manipulation of biological activities by non-invasive remote activation is focus of extensive research efforts that, recently, led to the development of different stimulation methodologies based on smart nanomaterials. For instance, magnetic fields, ultrasounds, heating, electric fields, light irradiation can be used in combination with physically-responsive nanomaterials, exploited as real “nanotransducers” [1]. Here, piezoelectric nanostructured materials and their applications in the nanomedicine field will be introduced, with particular attention to tissue engineering and regenerative medicine. Despite their impressive potentials, in fact, this kind of nanomaterials has not yet received significant attention for bio-applications. Our results strongly support the use of piezoelectric nanoparticles in nanomedicine, demonstrating as their exploitation is possible and realistic, and their impressive physical properties can be most useful for several applications, that range from sensors and transducers for the detection of biomolecules, to “reactive” substrates for tissue engineering and cell stimulation [2-3]. After a short introduction to the major classes of innovative piezoelectric nanoparticles that have attracted interest in the latest years, attention will be focused on the research carried out in our laboratories, introducing barium titanate nanoparticles, boron nitride nanotubes, and polymeric composites based on these nanomaterials. In particular, the first example will concern composite poly(vinylidene fluoride-trifluoroethylene), P(VDF-TrFE) / barium titanate nanoparticle (BTNs) films, prepared and tested as substrates for neuronal stimulation through direct piezoelectric effect. Films were characterized in terms of surface, mechanical, and piezoelectric features before in vitro testing on SH-SY5Y cells. BTNPs significantly improve piezoelectric properties of the films, and support good SH-SY5Y viability and differentiation. Mechanical stimulation elicited by the application of ultrasounds has been proven to promote Ca²⁺ transients and to enhance cell differentiation [4]. Piezoelectric films composed by P(VDF-TrFE) and doped with boron nitride nanotubes (BNNTs) were instead prepared as scaffolds for SaOS-2 osteoblast-like cell culture. After mechanical, surface, and piezoelectric characterization, osteogenic differentiation was evaluated in terms of calcium deposition, collagen I secretion, and transcriptional levels of marker genes (Alpl, Col1a1, Ibsp, and Sparc) in cells either exposed or not to ultrasounds as a source of mechanical stimulation [5].

ACKNOWLEDGEMENTS: This research is partially supported by the Compagnia di San Paolo Starting Grant Number 55_AI16GC01.

A biological tissue is a composite material with “bottom-up” hierarchical structure that is closely related to its heterogeneous function. The extracellular matrix modulates biochemical and biophysical signalling, and its rigidity is an important micro-environmental parameter that regulates the spatiotemporal dynamics of intercellular signalling. For this reason, many studies are focused on fabricating scaffolds processed at multiple scales with structural and mechanical properties that are optimal for eliciting specific response or mimic those found naturally. These scaffolds have to present large surface areas that have appropriate topology and biochemical cues (e.g., ligands) at the nanoscale for tissue adhesion, while also exhibiting integral porosity to allow for the exchange of molecules that maintain cellular function. In this talk, the use of a multiscale and multimaterial process will be presented to develop 3D in vitro model that can mimic the 3D complexity of natural tissue. These novel 3D in vitro models can be used for the study of physio-pathological condition and for the analysis of effects on cell activities of different biomolecule and/or drugs. For these reasons it is important combine different biomaterials natural and synthetic also in the form of hydrogels that can be processed with several printheads in order to mimic the physiological tissue environment in terms of topology, from nano to milli scale, in terms of biochemical cues and of mechanical properties as it happens in natural tissue. We designed, realized and characterized a multimaterial and multiscale scaffold fabrication approach that combine several micro and nano fabrication techniques such as: a) electrospinning, that is able to process several materials in form of nanofibers [1-3], b) Fused deposition modeling , that allows to realize 3D structure with a millimeters scale made of synthetic polymers [4]; c) piston based extrusion head that is able to process hydrogel materials from micro to milli scale [5]; and finally d) ink-jet head [6], that will allow to decorate the 3D structure with biochemical factors in well defined position in order to better mimic the natural tissue.

SmartBone®: The case of an innovative bio-hybrid bone graft, from lab-scale design to clinical translation and commercialization

G. Perale

Presenting Author: Giuseppe Perale, giuseppe@ibi-sa.com

1Industrie Biomediche Insubri SA, Via Cantonale 67, 6805 Mezzovico-Vira, Switzerland

INTRODUCTION: Bone is the second most transplanted tissue, just after blood, and early evidences of bone grafts date back even to ancient Egyptians. The last decades saw a constant decline of the use of autografts, the gold standard, and a parallel growth of alternative solutions, being however few and showing their limits [1]. To overcome such limitations, being inspired by nature bone architecture, we have developed a composite bone graft: a mineral matrix obtained by bovine-derived is reinforced with resorbable PLA-CL block copolymer embedding RGD-exposing collagen fragments onto its surface [2], commercially traded as SmartBone® (SB).

METHODS: SB has been widely investigated, also for regulatory purposes: composition has been assessed by inductively coupled plasma mass spectrometry, microstructure by microCT scan (1172 microCT Skyscan), mechanical performances have been assessed in compression, bending and torsion tests, biocompatibility was proven according to all ISO10993 prescriptions, both in vitro and in vivo animal [3]. Clinical performances were evaluated during investigative clinical trials in bone regeneration applications and mechanism of action was confirmed both during histologic studies [4] and in vitro assessments using human adipose-derived Stromal Vascular Fraction (SVF) [5]. After CE marking, SB has been introduced into the market and monitored via post-marketing surveillance in its clinical applications related to bone regeneration in all skeletal districts.

RESULTS & DISCUSSION: P/Ca ratio resulted 1.9, being the components of >98% of the mineral matrix; open and interconnected porosity was proven, with av. pore size in the 250-600 microns range; compression and torsional breakage stress resulted av. 26MPa, with an av. Young modulus of 1.3GPa. Altogether, clinical investigations in various skeletal districts and indications [3, 6, 7], histological studies and in vitro SVF-based investigations, confirmed the mechanism of action: SB is quickly colonized by host-cells and it is progressively substituted by healthy living bone, thanks to its high performances and its capability to spark the natural remodeling process.

CONCLUSIONS: Overall, with 60’000+ grafts performed in the last years, SB proved to be a safe and performing bone graft, sustaining bone regeneration in a wide spectrum of applications from traumatology to dentistry, from oncology to custom-made cases, and one of the few new biomaterials brought from lab design to market use in the last decade [1].

Presenting Author: Gowsihan Poologasundarampillai, g.poologasundarampillai@bham.ac.uk
School of Dentistry, Institute of Clinical Sciences, University of Birmingham, Birmingham, UK

Combination of bottom-up ‘soft-chemistry’ sol-gel processing and top-down manufacturing processes have allowed the synthesis of porous hierarchical structures for biomedical applications. Bioprinting, a layer-by-layer top-down manufacturing process, has the potential to produce biomaterials on demand, customised for individual patient’s needs. One of the potential barriers to future developments in this field is the limited choice of suitable materials. At present, hydrogels from natural biopolymers are used for 3D bioprinting. These have several limitations, such as batch-to-batch variation, low shape fidelity and limited post-printing strength. An alternative are advanced organic-inorganic hybrid materials developed using the sol-gel process. Conventional sol-gel hybrids cannot be used as bioinks due to the release of large amounts of ethanol during the synthesis. In this talk, we will present the development of novel sol-gel derived bioinks for the 3D printing of tissue constructs using novel biocompatible silica precursors. Such precursors can be reacted together at physiological benign condition to result in hybrid hydrogels that show comparable physical and cell-response to hydrogels of biopolymers origin. The hybrid approach presented in this talk offers a number of key advantages for bioprinting over natural polymers: compositional flexibility, improved mechanical properties and controlled degradation.
Cartilage extracellular matrix derived scaffolds for articular cartilage and bone regeneration
G. Cunniffe¹,²,³,⁴

¹3D Printing Centre of Excellence, Global Supply Chain, Johnson & Johnson, 152-160 Pearse Street, Trinity College Dublin ²Trinity Centre for Bioengineering, Trinity Biomedical Sciences Institute, Trinity College Dublin, Dublin, Ireland ³Department of Mechanical and Manufacturing Engineering, School of Engineering, Trinity College Dublin, Dublin, Ireland ⁴Advanced Materials and Bioengineering Research Centre, Trinity College Dublin and Royal College of Surgeons in Ireland, Dublin, Ireland

Extracellular matrix (ECM) derived biomaterials have been used clinically over 1 million times in the surgical repair of different tissues and organs [1,2]. Scaffolds used clinically are typically derived from small intestine submucosa (SIS) or pericardium, and while the ECM of these tissues clearly contain structural and regulatory biomolecules generally supportive of regeneration, it is unlikely that a single tissue source of ECM will be optimal for all clinical targets. This concept is strengthened by recent studies reporting that ECM derived biomaterials can direct the differentiation of mesenchymal stem cells (MSCs) towards the phenotype of the source tissue from which they were derived [3,4]. This motivates the development of tissue-specific ECM derived scaffolds, potentially consisting of different layers or lineage-specific regions, especially when attempting to regenerate complex multiphasic tissues such as the osteochondral unit of synovial joints. This talk will describe our experience with developing highly porous, cell instructive scaffolds from the decellularized ECM of different musculoskeletal tissues. It will demonstrate how scaffolds derived from growth plate ECM can support large bone defect healing, and that articular cartilage ECM derived scaffolds can support chondrogenesis of adult stem cells and the repair of critically sized cartilage defects. Furthermore, the talk will demonstrate how layered, tissue-specific ECM derived scaffolds can be used for regenerating spatially complex musculoskeletal tissues such as the osteochondral unit.

Epithelial stem cells: A real tool for effective regenerative medicine treatments
G. Pellegrini
Presenting Author: Graziella Pellegrini, graziella.pellegrini@unimore.it
University of Modena and Reggio Emilia Modena, Center for Regenerative Medicine “Stefano Ferrari”, Modena, Italy

Regenerative medicine has generated many efforts to explore new therapeutic potentials of both somatic and pluripotent stem cells with many possibilities envisaged for therapeutic applications. Hematopoietic and epithelial cells are extensively adopted for tissue regeneration, due to their high proliferative capacity and their accessibility. 30 years ago, the method for producing epidermis was discovered by cultivation from a small skin biopsy, allowing life-saving treatment of thousands severely burned patients in the following years. The importance of stem cell content was proven for tissues or organs in different pathologies. For instance, recent developments in cell-based therapy for ocular burns provided support for improvement and standardization of the cure for this disabling disease causing depletion of limbal stem cells. Indeed, biopsies taken from the healthy eye, or other autologous source as oral mucosa in bilateral blindness, can be used for their content of stem cells. Few of these therapies overcame the hurdles related to medicinal product regulation and became available to patients. The combined use of cell and gene therapy represents a further scientific approach for the treatment of congenital diseases. This approach was proven on hematopoietic cells and has recently been established using genetically modified epidermal cells for life-saving treatment on severe genetic diseases, as epidermolysis bullosa.
Discrimination of influence of cell adhesion and spreading area on hMSCs differentiation using micropatterns
G. Chen¹²
Presenting Author: Guoping Chen, Guoping.CHEN@nims.go.jp
¹Tissue Regeneration Materials Group, Research Center of Functional Materials, National Institute for Materials Science, Tsukuba, Japan ²Department of Materials Science and Engineering, Graduate School of Pure and Applied Sciences, University of Tsukuba, Tsukuba, Japan

Cell adhesion and spreading are manipulated by the cell/ECM interactions that play crucial roles in regulating cell functions. Many studies have reported that the physical properties of ECM including geometry, anisotropy, topography and rigidity can influence the mechanosensing of the microenvironment through regulating cell adhesion and spreading. However, it is unclear whether cell adhesion or spreading is the predominant factor to influence cell functions because it has been difficult to separate the two effects by conventional cell culture using uniform surfaces. In this study, the independent influence of adhesion and spreading area on differentiation of human mesenchymal stem cells (MSCs) was investigated by using micropatterning method to precisely control cell adhesion and spreading areas. A series of micropatterns having the same size and different cell adhesion area or having different size and the same cell adhesion area were prepared by UV photolithography for cell culture. The formation of FAs and the cytoskeletal organization in the cells cultured on the micropatterns were investigated to evaluate cell adhesion and spreading state. The mechanical properties of micropatterned cells and the transduction of cytoskeletal force into nucleus were characterized to reveal the mechanism of the influence. The osteogenic and adipogenic differentiation of MSCs were investigated to show how the adhesion and spreading areas independently influenced cell fate determination. The adhesion and spreading of human mesenchymal stem cells (MSCs) were manipulated by the micropatterns due to the regulation of focal adhesion formation. According to the available adhesive and spreading areas, cells assembled their cytoskeletal structure in different manners. However, the binding of myosin to actin fibers was mainly influenced by cell adhesive area. Meanwhile, cell mechanical state and the mechanotransduction were mainly determined by the adhesive area rather than spreading area. Furthermore, large adhesive area facilitated the osteogenic differentiation, while small adhesive area promoted the adipogenic differentiation. Cells with the same adhesive area but different spreading areas had similar potential of differentiation. The results indicated that the adhesive area rather than spreading area played more important roles in regulating cell functions in an isotropically micropatterned cells. The results should inspire the design of biomaterials to process in an effective manner for manipulation of stem cell differentiation.

Do we need to better mimic bone microstructure to observe bone cell behavior in vitro?

G.C. Reilly¹,²

Presenting Author: Gwendolen Reilly, g.reilly@sheffield.ac.uk

¹Insigneo Institute for in silico medicine and ²Department of Materials Science and Engineering, University of Sheffield, Sheffield, UK

In vitro 3D bone models and ‘bone-on-a-chip’ style approaches have been advocated as an alternative to in vivo experiments, providing a more physiological environment than monolayer culture, with the opportunity to use patient specific cells for human disease relevance. However, bone is a particularly challenging tissue to create ‘on a chip’ due to its dense composite structure perfused by blood vessels in osteonal canals, in which ellipsoid cells with multiple processes reside, the osteocytes. The bone extracellular matrix (ECM) is a highly organized structure with arrays of collagen fibres in parallel within one lamella (layer) but changing in orientation between lamellae. Monolayer culture, often described as effectively ‘2D’, does not retain cells’ natural morphology, as cells are constrained to flatten onto a highly brittle and stiff substrate, different from the native bone microenvironment. For example, much previous work in our laboratory used fluid flow over this monolayer to mimic the fluid environment of bone but the cells responses were likely strongly influenced by the non-osteocyte like shape that they are forced to take in monolayer culture. Bone tissue engineering has made huge advances in enabling 3D culture of osteoprogenitor cells in a range of scaffolds and devices. There is much evidence that cells can be easily encouraged to create a ‘bone-like’ 3D matrix in these environments. In the sense that the matrix is evidenced to contain collagen, other ECM proteins and calcium phosphate/ hydroxyapatite mineral. However in most of these 3D cultures cells reside in clusters or line scaffold surfaces and collagen and mineral are observed in non-organised patches. Recently, our group and others have made advances in better re-creating the bone-like environment and several studies have reported osteocyte-like morphologies in tissue engineered bone. Here, I will mainly focus on two approaches in our laboratory to improve mimicking of bone matrix in vitro. The first involves using emulsion templating (PolyHIPE) techniques to create hierarchical structures with pores of the order of magnitude of osteocyte lacunae and of the order or magnitude of osteonal canals. Such scaffolds are highly tunable in terms of stiffness and in our group we can have cast, printed and created microfluidic devices from such materials. In another approach we use electrospun scaffolds with controlled fibre alignment to guide ECM production by bone cells and re-create lamellar-like structures. It is still not clear from these studies how closely the microstructural morphology of bone needs to be replicated before we can say such models can avoid the need for in vivo studies. However it is clear we are getting much closer to humanized, physiological bone mimics which could be used for better understanding of bone in health and disease.

Bioprinting of gene-activated scaffolds for musculoskeletal regeneration: Cell-based growth factor delivery

H Lin1,2
Presenting Author: Hang Lin, hal46@pitt.edu
1Center for Cellular and Molecular Engineering (CCME), Department of Orthopaedic Surgery
2McGowan Institute for Regenerative Medicine, University of Pittsburgh School of Medicine, Pittsburgh, PA, U.S.A.

Bone morphogenetic protein 2 (BMP-2) is a commonly used inductive factor for osteogenesis of bone marrow mesenchymal stem cells (BMSCs), but sustained delivery of active BMP-2 protein remains challenging. In this study, we first used lentiviral constructs to ex vivo transduce human bone marrow-derived stem cells with human bone morphogenetic protein-2 (BMP-2) gene (BMP-hBMSCs). We then introduced these cells into a hydrogel scaffold using an advanced visible light-based projection stereolithography (VL-PSL) technology, one type of 3D printing technologies that is compatible with concomitant cell encapsulation and amenable to computer-aided architectural design, to fabricate scaffolds fitting local physical and structural variations in different bones and defects. The results showed that the BMP-hBMSCs encapsulated within the scaffolds had high viability with sustained BMP-2 gene expression and differentiated toward an osteogenic lineage without the supplement of additional BMP-2 protein. In vivo bone formation was also observed as early as 14 days post-implantation [1]. We also tested another strategy through gene-activated matrix. We incorporated viral vector encoding BMP-2 gene (Lv-BMP, BMP group) or Green fluorescent protein (GFP) gene (Lv-GFP, GFP group) and human BMSCs into gelatin solution, which were then subjected to VL-PSL. We hypothesized that the Lv-BMP would in situ transduce encapsulated BMSCs, resulting in robust osteogenesis and bony tissue formation without the supplement of extra BMP-2 protein. To test the in vivo bone formation capacity, constructs from GFP or BMP group were implanted intramuscularly in SCID/J mice. Micro–computed tomography (µCT) imaging showed detectable mineralized areas in BMP group, which is restricted within the scaffolds, suggesting a localized bone formation in muscle. Similar areas were not present in the GFP control. Alizarin red staining and immunohistochemistry (IHC) of GFP and osteocalcin indicated that grafted hBMSCs, not host cells, contributed majorly to the bone formation. This novel one-step, gene-activated and live cell encapsulated scaffold fabrication procedure is thus potentially applicable for point-of-care treatment of bone defect.

ACKNOWLEDGEMENTS: Financial support was received from the National Institutes of Health (1UG3TR0021360 and 5R01EB019430).

Official data say that the global tissue engineering market size was valued at around 5 billion US$ in 2016. Growing potential of tissue engineering procedures in the treatment of tissue damages is supporting the market growth. European data show that 1500 procedures using tissue engineered products have been performed and reported annually between 2016 and 2018. (Martin I, et al. The Survey on Cellular and Engineered Tissue Therapies in Europe in 2013. Tissue Eng. 2016;22(1-2):5-16). According to Medicare more than 900,000 surgeries are performed in the US for bone reconstruction or replacement. The segments - Orthopaedics, musculo-skeletal and spine held majority of the market chair in the year 2014 owing to the rising musculo-skeletal disorders. In Europe, most of the start-up companies have failed to participate in this growth. The lack of venture capital and increase in the regulatory requirements have created a hostile climate for start-up companies in Europe for the last 10 years. Companies are now entering into collaboration to gain advantages on research and technology competencies offered by other competitors. Gaining clinical evidence for the use of tissue engineered products is a long lasting process, particularly in the field of musculo-skeletal disorder/research. The increase of minimal invasive procedures due to technical innovation in the field of medical devices are increasing the requirements for tissue engineered products in many medical specialties. The medical unmet need and challenges, in addition, has to be evaluated continuously. The fragmentation of research and development of tissue engineered products and clinical application is requiring an urgent harmonization for the needed translational process.
Innovative approach for bone and cartilage tissue engineering
H. Havitioglu1,2,3
Presenting Author: Hasan Havitioglu, hasan.havitioglu@deu.edu.tr
1Dokuz Eylul University, Faculty of Medicine, Department Of Orthopedics and Traumatology, İzmir, Turkey
2Dokuz Eylul University, Department of Health Sciences, Biomechanics Department, İzmir, Turkey
3Dokuz Eylul University, Bone - Cartilage Tissue Biotechnology Application and Research Center (KEKDOB), İzmir, Turkey

Cartilage and bone tissue engineering is highly studied topic for about 20 years. However, it could not be transferred to clinical studies. Therefore, this abstract aims to combine in vitro and in vivo studies for cartilage and bone tissue engineering based on scaffolds with various fabrication techniques. Scaffolds should mechanically and physiologically mimic the cartilage and bone tissue. Porosity, mechanical strength, cell adhesion, biocompatibility, cell proliferation, mineralization and toxicity are important characteristics. In order to improve scaffolds poor mechanical properties, while preserving the porous structure, it is possible to coat the scaffold with synthetic or natural polymers. It is better if you produce scaffolds from natural biomaterials. We produce various bone and cartilage tissue scaffolds with different techniques such as lyophilization, 3D printing and electrospinning. By using Polylactic Acid (PLA), loofah (Luffa Cylindrica), chitosan, collagen, Poly-3-hydroxybutyrate-co-3-hydroxyvalerate (PHBV), fish scale, cellulose acetate, etc. we produced various composite scaffolds. Their chemical, morphological and mechanical properties should be determined by using several tests. Scaffold morphologies were tested by Scanning Electron Microscope (SEM). Also, by using Fourier Transformed Infrared Spectroscopy (FT-IR) chemical compositions were tested. Their mechanical properties were tested by compression or tension tests. Moreover, swelling ratios, thermal gravimetric analysis (TGA) and porosity ratios were completed. Biocompatibility tests could be performed by using mesenchymal stem cells or cell lines. Stem cells are frequently used in regenerative medicine. They can be obtained from many sources such as bone marrow, adipose tissue, periosteum, etc. Viability, cytotoxicity, mineralization, Glucose-Amino-Glycan (GAG) activities were determined by using spectrophotometer. Moreover, some of them were used in Wistar Albino rats and New Zealand rabbits. Analysis indicated, scaffolds are successfully mimicked bone and cartilage tissue. They are suitable for in vivo regeneration. Also, they could be used to increase regeneration. Histological studies showed promising results. Pre-clinical studies were completed. They should be used in clinical studies.

Induction of angiogenesis by placenta derived stem cells and matrix for tissue engineering and regenerative medicine

H. Niknejad

Presenting Author: Hassan Niknejad, niknejad@sbmu.ac.ir
Department of Pharmacology, School of Medicine, Shahid Beheshti University of Medical Sciences, Tehran, Iran

Despite huge progress in the fields of tissue engineering and regenerative medicine, angiogenesis is still a major challenge. Human placenta including amnion and chorion, cord blood and its matrix have some properties which make them an appropriate source of stem cells and scaffold for tissue engineering. The placenta derived epithelial and mesenchymal cells possess the characteristics of pluripotent/multipotent stem cells which have the capability to differentiate into all three germ layers and can be obtained without ethical problem. Moreover, placenta derived matrix demonstrates properties of an appropriate scaffold tissue substitute via different types of extracellular proteins such as collagens, laminins and fibronectins which serve as an anchor for endothelial cell attachment and proliferation, a substrate for cell delivery and a reservoir of drugs and growth factors involved in angiogenesis. The recent data demonstrate that amniotic epithelial and mesenchymal exosomes have their specific effects on angiogenesis. Moreover, based on in vitro aorta ring assay and microinvital microscopy, both sides of amniochorion membrane can serve as a scaffold for prevascularization of three dimensional tissue engineered constructs. Recently, new insights into developing new methods for surface modification and cross-linking, construction of placenta based hydrogels and micronizing approaches emerged new fields in vascular tissue engineering [1,2].

Organoids are defined as ‘structures resembling an organ’ and are a 3D adult stem cell culture system. Originally developed from mouse intestinal stem cells, organoid cultures have since then been established from a wide range of tissues and species, including human. Organoid development was a breakthrough in many research areas, as it allowed for highly proliferative robust primary cultures from patient samples from various organs (e.g. stomach, intestine, pancreas and liver). Organoids have already proved to be a valuable tool for disease modeling research (e.g. in human cystic fibrosis) and are also considered for transplantation purposes. Our lab studies canine and feline liver disease and regeneration and established organoid cultures from dog and cat liver [1]. Interestingly, dogs and cats develop spontaneous liver diseases that have clinical counterparts in human hepatology. For example, dogs can suffer from genetic copper toxicosis resulting in chronic hepatitis and cirrhosis similar to human Wilson’s disease. Organoids were used to model and genetically correct this disease in vitro [2] and subsequently transplanted in vivo in dogs with copper storage disease. In cats a specific syndrome of liver steatosis is observed upon prolonged periods of anorexia. Feline hepatic steatosis resembles human fatty liver disease, an increasingly prevalent syndrome associated with Western diet and lifestyle. Feline liver organoids were cultured and fed excess fatty acids, which resulted in cellular steatosis [3]. Feline organoids turned out to be more prone to lipid accumulation than human organoids, exemplifying them as an interesting translational research model. Current studies focus on lipid-lowering drug interventions in feline fatty organoid cultures.

Hybrid bioprinting with vascularized spheroids
H.A. Declercq1,2
Presenting Author: Heidi Declercq, heidi.declercq@ugent.be
1Tissue Engineering Group-Bioprint Facility, Department Human Structure and Repair, Faculty of Medicine and Health Sciences, Ghent University, Gent, Belgium 2GATE (Ghent Alliance for Tissue Engineering), Gent, Belgium

The main challenge in tissue engineering is the creation of a functional engineered vascular system with multiscale vessel networks from capillaries to large vessels within complex 3D structures such as heart, muscle, bone, adipose tissue,… Strategies to engineer these tissues can be categorized in top-down, scaffold-based approaches and bottom-up, developmental biology inspired approaches (scaffold-free). In the bottom-up approach, a 3D tissue is build by assembling modular tissues (spheroids). Although progress was made in both strategies, the inability in fabrication of 3D vascular networks has limited applications in tissue engineering. Now it has become clear that individual approaches will not succeed to the end-goal. In this lecture, we will focus on combining the advantages of both approaches that will have a synergistic effect for future fabrication of 3D tissue analogs. In our approach, cellular building blocks with self-assembling properties and mimicking the tissue of interest will be combined with cell instructive biomaterials. The cellular building blocks are either tissue-specific or vascular. Using a high-throughput non-adhesive agarose microwell system (2865 pores, diameter 200 µm) uniform spheroids with an ideal geometry and diameter (< 200 µm) for bioprinting are formed. High quality homocellular building blocks were already generated that form tissue-specific cellular building blocks ((fibro)cartilage [1], adipose tissue, bone tissue,…

starting from adult cell types or human mesenchymal stem cells derived from adipose tissue or pulp tissue. Dependent on the tissue type, stable spheroid formation was influenced by cell culture medium, cell culture environment and cell types. These tissue-specific spheroids can be combined with vascular spheroids providing the capillary like network. By coculturing endothelial cells with fibroblasts and/or adipose tissue derived mesenchymal stem cells as supporting cells, and applying the favourable coculture ratio, viable vascular spheroids were obtained [2]. Endothelial cells spontaneously organized into a capillary like network and lumina were formed, as shown by immunohistochemistry and transmission electron microscopy. Moreover, the spheroids were able to assemble at random in suspension, creating a macrotissue. The tunable mechanical characteristics of hydrogels (crosslinking efficiency) can influence outgrowth and fusion of the spheroids. 3D bioprinting of vascular spheroids in photocrosslinkable gelatin-methacrylamide was performed with the 3D Discovery (RegenHu) and resulted in high viability and fusion of the vascular spheroids into a vascular network. Reorganization of cells, throughout the entire fused construct and by inoculating with capillaries of adjacent spheroids, creates a branched capillary like network. Combining the advantage of the natural capacity of microtissues to self-assemble and the controlled organization by bioprinting technologies, these vascularized spheroids can be useful as building blocks for the engineering of large vascularized 3D tissues.

Did we run out of ideas? The importance to spark innovation in tissue engineering research and traumatology
H.R. Redl¹,²
Presenting Author: Heinz Redl, Office@TRAUMA.LBG.AC.AT
¹Ludwig Boltzmann Institute for Experimental and Clinical Traumatology, AUVA Research Centre, Austria ²Austrian Cluster for Tissue Regeneration

INTRODUCTION: What if patients and clinical experts could spark and define the direction of multidisciplinary science projects without knowing the scientific literature? The LBG Open Innovation in Science Center and the LBI for Experimental and Clinical Traumatology set up a project in order to fill the gap between clinical knowledge and scientific research. This novel approach in the field of Traumatology aims to bridge the gap between the conventional bench-to-bedside approach within this discipline.

METHODS: ‘Tell us!’ — about accidental injuries leverages crowdsourcing methodology to spark new lines of research [1]. Over a period of 4 months, a broad community of international stakeholders and participants was established and motivated to submit research questions in the area of the diagnosis, treatment and rehabilitation of patients with major traumatic accidents.

RESULTS & DISCUSSION: 227 participants registered to the tell-us.online platform. In total, 118 users contributed a total of 190 research questions within 4 months of crowdsourcing (Mai — August 2018). Overall, 60% of all contributions came from experts coming from physiotherapy (n = 13), MDs (n = 13) and occupational therapy (n = 11). Most contributions came from the field of nursery with research questions of great detail (e.g.; „What is the effect of irradiated amnion on Chondrogenesis in osteochondral defects in talus or knee?“) and more general questions (e.g. „How can a multidisciplinary rehabilitative approach improve the functional outcomes in geriatric clients with cognitive disorders?“).

CONCLUSIONS: Applying Open Innovation in Science is a major quest in order to open up scientific workflows. In particular, using crowdsourcing to identify research questions from bedside-to-bench can be a method of great potential to spark innovation in the field of Traumatology.

ACKNOWLEDGEMENTS: No financial interests to disclose.

Towards a better knowledge of cell and tissue responses to strontium-containing bioactive glasses
H. Autefage

INTRODUCTION: The development of synthetic bone substitutes that are able to repair critical-sized bone defects requires the combination of an optimized composition and architecture, which remains challenging to achieve, partly because of a lack of clear understanding of the mechanisms by which biomaterials drive bone regeneration. Strontium ions have proven anti-osteoporotic properties and can easily be substituted to calcium in inorganic materials. While, strontium incorporation within BG has been shown to increase osteoblastic activity and decrease of osteoclastic activity in vitro, and strontium-containing inorganic bone substitutes increased osteointegration in vivo in small animal models, the mechanisms by which strontium-loaded materials favor bone formation remain unclear. Here, we applied discovery-driven approaches to better identify how strontium incorporation within BG affects osteoprogenitor cell global responses, bone formation and bone/material interaction.

METHODS: A porous SrBG (pSrBG) was created by in situ hybridization, implanted in critical-sized defects in an ovine model, and bone formation was assessed with regards to quantity and quality. To better understand how strontium incorporation into BGs affected human mesenchymal stromal cells (hMSCs) through changes in the ionic microenvironment, a series of SrBGs based on 45S5 composition was produced, and hMSCs were treated with SrBG dissolution extracts before a whole-genome analysis was performed.

RESULTS & DISCUSSION: When implanted in a critical-sized defect in sheep, pSrBG released strontium and outperformed 45S5 control particles with regards to bone-to-material contact and bone architecture. Interestingly, the multiscale analysis of the newly-formed bone quality identified differences between pSrBG and 45S5. In vitro, our objective analysis of hMSC global responses to SrBG dissolution products revealed that Sr2+ loading within 45S5 BG composition resulted in strong unexpected changes in the cell metabolism at the gene and cellular levels. Those changes translated to modifications in the cholesterol and lipid raft membranous contents as well as an increased actomyosin activity.

CONCLUSIONS: This work showed that the simple incorporation of Sr2+ in BG can have a strong influence on cell global response. It also illustrated how non-discriminative discovery-driven approaches and in-depth tissue analysis can uncover unexpected cell and tissue responses to specific material properties. By providing a better knowledge of the materials’ effects on cells and tissues, such strategies would likely facilitate the development of future biomaterials.

Challenges of manufacturing MSCs for clinical development
H. Roelofs¹
Presenting Author: Helene Roelofs, H.Roelofs@lumc.nl
Center for Stem Cell Therapy, Department of Immunohematology and Blood Transfusion, Leiden University Medical Center, Leiden, The Netherlands

Ample experience is available for drug manufacturing involving the culture of cells. Manufacturing processes for drugs where the cells themselves are the active ingredient are relatively new and come with new manufacturing challenges, especially when the cells of interest are adherent cells. MSC products for early phase clinical trials, generated with mainly manual processes - including cell expansion in flasks and multiple open process steps in heavily controlled production environments - have indicated to be safe and efficacious in a number of patient populations. However, the scale-up to increased production volumes has proven to be cumbersome. Simply multiplying the manual process leads to extremely high production costs, driving the price for the cellular drugs to levels that are limiting patient access. Changing the production process itself has its effects on main manufacturing attributes such as identity, purity, safety and potency, hampering clinical development. Here, our experience with MSC production scale-up and automation is discussed as well as alternative options that allow manufacturing scale-up to stay in tune with clinical development.

Modeling of limbal stem cell differentiation using human pluripotent stem cells and tissue engineering
H. Skottman¹

Presenting Author: Heli Skottman, heli.skottman@uta.fi
¹Faculty of Medicine and Health Technology, BioMediTech Institute, Tampere University

Corneal blindness affects millions of people worldwide, and there is a constant shortage of high quality donor tissue. Engineering a corneal transplant that could effectively restore functional limbal epithelial stem cells (LESC) and regenerate the corneal epithelium and stroma is an important goal. To achieve this, differentiation of LESCs from human pluripotent stem cells (hPSC-LESC) provides new tools for studying corneal epithelial renewal and providing exhaustless source of cells for regenerative therapy. In addition, human adipose stem cells (hASCs) provide an appealing cell source for corneal stromal regeneration due to their capacity to differentiate towards corneal keratocytes, immunomodulatory properties and good availability from healthy adult donors. We have previously established an efficient and clinically relevant method to produce LESC-like cells from hPSCs [1]. With this method, we are able to produce a cell population highly expressing clinically relevant corneal progenitor markers p63α/p40 in defined and serum-free culture conditions. With detailed analyses of the cell differentiation in several time points, we have gained further knowledge of the differentiation pathway involved. Interestingly, ABCG2, a universally proposed marker of limbal stemness, is only transiently expressed in culture conditions supporting corneal epithelial differentiation. Thus, this cell population at early state of differentiation represented a noticeably different LESC-like phenotype (being ABCG2-positive) as compared to later arising cell population with high level of progenitor marker expression (ABCG2-negative/p63a-positive). Based on our current research hypothesis, these two cell populations may represent functionally different stem/progenitor populations with implications in their regenerative efficacy. For further study and possible utilization of these therapeutic cells, we use novel biomaterials and tissue engineering techniques. In our efforts to develop new constructs for corneal regeneration, we combine the hPSC-LESCs with hASCs into functional biomaterial scaffolds for regeneration of both the corneal epithelium and stroma. To this end, we have recently shown the application of a novel laser-assisted bioprinting (LaBP) method for creating corneal-mimicking structures composed of clinically relevant bioinks, hASC-containing stromal layers and overlying multilayered epithelium bioprinted from hPSC-LESCs [2]. In addition, our new approach for creating layered corneal epithelial and stromal implants with increased transparency takes advantage of our earlier work with hyaluronic acid (HA) based hydrogels for hASCs delivery to the cornea [3]. With incorporation of dopamine moieties to HA hydrogels, we have been able to construct tissue-adhesive implants containing hASCs in the bulk hydrogel and hPSC-LESCs on the surface, and we have demonstrated their proof-of-concept implantation in porcine corneal organ culture model.

Medical evaluation of mussel protein bioadhesives
H. J. Cha

Presenting Author: Hyung Joon Cha, hjcha@postech.ac.kr

Department of Chemical Engineering, POSTECH, Pohang 37673, Korea

Marine mussel adhesion is known to be mediated by adhesive proteins, which are secreted through the mussel byssus and have great potential as biologically and environmentally friendly adhesive biomaterials due to their biocompatibility and biodegradability. In addition, mussel adhesive proteins (MAPs) have strong adhesion ability even on wet surfaces due to unique amino acid arrangements and composition. However, researches using the natural amino acid composition have been limited due to extreme difficulties in obtaining sufficient quantities of MAPs for practical applications and commercialization. We successfully produced redesigned MAP using a bacterial expression system and this bioengineered MAP showed significant adhesion ability and biological safety. We successfully developed a photo-activated MAP-based hydrogel bioadhesive (LAMBA) inspired by insect dityrosine crosslinking chemistry [1]. The developed LAMBA exhibited substantially stronger bulk wet tissue adhesion than commercially available fibrin glue and good biocompatibility in both in vitro and in vivo studies. Besides, the easily tunable, blue light-activated crosslinking enabled an effective on-demand wound closure and facilitated wound regeneration. Based on these outstanding properties, LAMBA holds great potential as an ideal medical glue for diverse medical applications, including sutureless wound closures of skin and internal organs and effective regeneration of wounded tissues. In addition, we developed a unique water-immiscible MAP-based bioadhesive (WIMBA) exhibiting strong underwater adhesion which was employed by two adhesion strategies of mussels; Dopa-mediated strong adhesion and water-immiscible coacervation [2]. The developed biocompatible WIMBA successfully sealed ex vivo urinary fistulas and provided good durability and high compliance. Thus, the developed WIMBA could be used as a promising sealant for fistula management with further expansion to diverse internal body applications. We developed and evaluated MAP as innovative bioadhesive materials for diverse medical area including scarless wound closure and fistular sealing with proper fabrications and formulations.

Figure 1: Schematic representation of WIMBA employed by the chemistries of DOPA and complex coacervation for urinary fistula sealing [2].

Simplifying corneal regeneration via the use of pliable tissue delivery microfabricated membranes
I. Ortega Asencio

Presenting Author: Ilida Ortega Asencio, i.ortega@sheffield.ac.uk

1Bioengineering and Health Technologies Group, The School of Clinical Dentistry, The University of Sheffield, Sheffield, UK

Corneal disease affects millions of people worldwide with higher prevalence in developing countries. Corneal transplantation to replace damaged corneas has been used for decades to treat patients with corneal impairment but replacing corneas alone cannot solve corneal scarring if the patient lacks corneal stem cells (1-2). The use of membranes as cell carriers for aiding in corneal disease has been relatively successful, for example, the amniotic membrane (AM) is being used worldwide as a corneal cell carrier (3). Unfortunately, AM carries a risk of viral transmission which can only be reduced by using careful tissue banking protocols. The Sheffield cornea team have been working together with LV Prasad Institute (LVPEI, India) with the aim of delivering new alternatives for simplifying corneal treatments and therefore increasing their accessibility, focusing on (i) the use of tissue explants instead of laboratory expanded cells (Simple Limbal Epithelial Transplantation, SLET which is used now successfully in more than 100 centres worldwide) and (ii) the development of a synthetic AM substitute made of PLGA 50:50 (4). The development of this synthetic PLGA membrane has achieved many of its milestones but frustratingly the membrane that has been developed is stiffer than expected; this occurred as a result of exhaustive solvent removal to reduce solvent concentrations to levels permitted for clinical use (the solvent acts as a plasticizer and when removed the material becomes brittle). Our current challenge is to reduce the stiffness of our previously developed corneal electrospun scaffolds via the utilisation of different solvent-systems and plasticizers while avoiding excessive levels of residual solvent. In parallel to the development of a plain polylactic glycolic acid (PLGA) membrane for corneal disease, Sheffield has been working on the development of a next generation membrane which includes micro features to mimic the limbal niches of the cornea. These niches provide physical support to the stem cells which need to last a lifetime, generating daughter cells to renew the cornea. Specifically, we have developed a corneal PLGA ring in which we have included microfeatures which mimic to a degree the shape and the size of the corneal stem cell niches in the eye. These features are regarded by our clinical collaborators at LVPEI in India as potentially very useful to assist them in stem cell survival as well as providing convenient pockets in which to place tissue explants at the time of surgery. In summary, clinical collaborators in India have been very positive regarding our AM substitutes and they have provided us with very useful feedback which we are now implementing. In essence, we are working towards the improvement of the mechanical performance of current PLGA membranes and we are developing new microfeatured ring scaffolds in which surgeons will able to hold tissue explants in place without the need of using expensive and not easy to access glues (e.g. fibrin).

International standardization and electronic coding of the terminology for regenerated tissue products
I. Slaper-Cortenbach

Presenting Author: Ineke Slaper-Cortenbach, inekeslaper@gmail.com
1Regenerative Medicine Technical Advisory Group (RMTAG), ICCBBA, P.O. Box 11309, San Bernardino, CA 92423-1309, USA

INTRODUCTION: International standardization and electronic coding of terminology for medical products of human origin (MPHO) began in 1994 with the introduction of the ISBT 128 Standard for blood products. In the following decades, the development of the Standard continued and its use expanded steadily to diverse categories of MPHO such as cellular therapy, tissues, organs, and others. The RMTAG was formed to develop a global ISBT 128 terminology for regenerative medicine products. It is composed of technical experts and representatives from professional societies, such as ISCT and TERMIS EU.

METHODS: The ISBT 128 classification ranks: (1) Categories, (2) Classes, and (3) Attributes. Discussions within the RMTAG were primarily accomplished via conference calls and email exchange. Mechanisms for conflict resolution, such as group vote, were used to resolve terminology issues. Comments on proposed terminology were also collected via open public consultation.

RESULTS & DISCUSSION: The product category Regenerated Tissue has been proposed for regenerative medicine products. These products have been categorized into 12 main product groups called Classes (e.g., regenerated tissue, regenerated skin). Attributes that define the specific features of a product have been organized by affinity to eight Attribute Groups (e.g., type of cells, delivery method). Classes and Attributes are combined in the Product Description (CLASS │ Attribute │ Attribute) to uniquely define a product. To accomplish electronic coding, each Product Description is assigned an internationally unique five-character Product Description Code (PDC) which can be electronically coded into a linear or two-dimensional bar code, or other symbologies.

CONCLUSIONS: The ISBT 128 Standard provides a comprehensive and highly flexible system for describing regenerative medicine products and assigning product codes in an electronically readable format. The international partnership and consensus fostered by RMTAG are crucial to driving advancement of ISBT 128 and keeping pace in the fast emerging field of regenerative medicine.
Cytoprotective single-cell nanoencapsulation
I. S. Choi
Presenting Author: Insung S. Choi, ischoi@kaist.ac.kr
Center for Cell-Encapsulation Research, Department of Chemistry, KAIST, Korea

Nature has developed a fascinating strategy of cryptobiosis for counteracting the stressful, and often lethal, environmental conditions. For example, certain bacteria sporulate to transform from a metabolically active, vegetative state to an ametabolic endospore state. The bacterial endospores, encased within tough biomolecular shells, withstand the extremes of harmful stressors, such as radiation, desiccation, and malnutrition, for extended periods of time and return to a vegetative state by breaking their protective shells apart when their environment becomes hospitable for living. Inspired by cryptobiosis found in nature, researchers have sought to chemically control and tailor the metabolic behaviors of non-spore-forming cells as well as enhancing their viability against adverse environmental conditions, by forming thin (< 100 nm), tough artificial shells [1-3]. These living “cell-in-shell” structures, called artificial spores, enable chemical control of cell division, protection against physical and chemical stresses, and cell-surface functionalizability, armed with exogenous properties that are not innate to the cells but are introduced chemically. The field has further advanced to the stage of chemical sporulation and germination, where cytoprotective shells are formed on living cells and broken apart on demand. The (degradable) cell-in-shell hybrids are anticipated to find their applications in various biomedical and bionanotechnological areas, such as tissue engineering, cytotherapeutics, high-throughput screening, sensors, and biocatalysis, as well as providing a versatile research platform for single-cell biology.

ACKNOWLEDGEMENTS: Financial support was received from the Basic Science Research Program through the National Research Foundation of Korea (NRF) funded by the Ministry of Science, ICT and Future Planning (MSIP) (2012R1A3A2026403).

Natural polymers of bacterial origin and their biomedical applications
I. Roy
Presenting Author: Ipsita Roy, royi@wmin.ac.uk
School of Life Sciences, College of Liberal Arts and Sciences, University of Westminster, London, UK

Bacteria produce a large variety of natural polymers including Polyhydroxyalkanoates (PHAs), Bacterial Cellulose, Poly-g-glutamic acid, Alginate and Pullulan. As opposed to other natural polymers that are extracted from natural sources these polymers are produced using bacterial fermentation. Hence, their production is as controlled and regulated as synthetic polymers, a great asset for translational products. PHAs are natural polymers produced by bacteria under nutrient limiting conditions. These polymers are biodegradable and biocompatible in nature and hence can be used in a variety of medical applications such as tissue engineering, wound healing, medical device production and drug delivery. Due to their varied mechanical properties and degradation rates, PHAs can be used to replace a range of tissue types including bone, nerve, cartilage, pancreas, cardiac and skin. In addition, they can be used for short term and long term controlled drug delivery. We have explored various modes of PHA production and their application in hard and soft tissue engineering, biodegradable stent production, nerve conduit production, cardiac patch development, wound healing and controlled drug delivery applications. Bacterial cellulose is another natural polymer produced using static bacterial fermentation. This too is highly biocompatible, has extraordinary mechanical properties and in its natural form is a nanostructured hydrogel highly suitable for the development of wound healing patches. We have initiated the development of antibacterial wound healing patches based on bacterial cellulose. Overall natural polymers have huge potential in biomedical applications and are the next generation sustainable, biocompatible materials, ready to revolutionise the medical world.
Research integrity and publication ethics
I. Bayindir-Buchhalter¹
Presenting Author: Irem Bayindir-Buchhalter, ibayindirb@wiley.com
¹Wiley-VCH; Weinheim, Germany

While growing research output is a must to advance a scientific career, reporting research findings should be tied to respecting publication ethics and maintaining integrity. In her talk, Dr. Irem Bayindir-Buchhalter, Associate Editor for the Advanced family of journals, will address several publishing integrity concerns, from plagiarism to authorship rights and conflicts of interest. Come by for a discussion on how integrity will improve the impact of your research.
Horses as large animal models of experimentally induced and naturally occurring musculoskeletal disease

I. Ribitsch

Presenting Author: Iris Ribitsch, iris.ribitsch@vetmeduni.ac.at
Department for Companion Animals and Horses, Vetricm, University Equine Hospital, Vetmeduni Vienna, Vienna, Austria.

This presentation is following the idea of “One Health” for expanding interdisciplinary collaborations and joining efforts in the development and evaluation of new methods for the prevention and control of disease across species (in this case horses and humans). As one of the few species suffering from naturally occurring musculoskeletal injuries and dysfunction similar to humans, the horse lends itself for this role as it would not only serve as an animal model, but also as a beneficiary of improvements in treatment. As athletic individuals, horses incur idiopathic primary or sports related injuries. An important aspect of clinical research is the precise demonstration of the initial injury, the disease progress, outcome and follow up. The validated applicability of advanced diagnostic methodologies in horses such as arthroscopy and MRI (together with scoring approaches), ultrasound, radiographs, CT and scintigraphy, has made the horse a popular model for which non-terminal studies with thorough evaluation and monitoring are possible. Also second-look arthroscopy and serial sampling are feasible. Moreover, the large size of horses allows for the creation of critical size defects or multiple defects and offers a high amount of material that can be sampled for analysis. Controlled postoperative exercise programs and rehabilitation protocols using e.g. treadmills and horse walkers further support standardization of the results. More recently a broad offer of modern methods to further objectify outcome measures became available including gait kinematics (e.g. lameness locators) and/or kinetics using force plate/ground reaction force analysis. In addition, the horse fulfils the requirements of the European Medicines Agency (EMA), the USA Federal Food and Drug Administration and the International Society for Stem Cell Research (ISSCR) who recommend the use of large animal models to evaluate efficacy, durability, dose response, degradation and safety prior to obtaining market approval of advanced therapeutic medicinal products (ATMPs). Despite obvious anatomic differences between the horse and the human (quadruped versus biped) there are striking similarities when comparing the corresponding anatomical structures. Thus, horses constitute an ideal animal model and studies performed in the horse could serve as preclinical data for human medicine.
How can I contribute to a better scientific community within TERM?
I. Martin
Presenting Author: Ivan Martin, Ivan.Martin@usb.ch
Department of Biomedicine, University Hospital Basel, Switzerland

The field of tissue engineering and regenerative medicine (TERM) has reached a maturity stage, with recognition as a scientific domain of its own and some evidences of promising clinical/commercial fruition. As for any individual coming of age, such progression requires increased awareness of the associated responsibilities. Starting from analysis of the own mistakes and weaknesses, this lecture will offer a personal view on principles of ethics and overall practice of good science that may need to be consolidated in the working routine of TERM affiliates, especially of students and young investigators. Some of the discussed topics will be related to general personal behaviour within a scientific community. Others will have a more specific link to the TERM field, around the challenge of crossing boundaries of several disciplines while addressing fundamental questions of deep scientific relevance. The intent of the lecture, far from the pretension of a moral preach, is to reflect on how TERM can further impact science and society, while receiving growing respect and consideration by other research domains.
Therapeutic opportunities of dental pulp stem cells
I. Lambrichts
Presenting Author: Ivo Lambrichts, ivo.lambrichts@uhasselt.be
Department of Morphology, Biomedical Research Institute, Hasselt University, Diepenbeek, Belgium

Over the past decade, dental tissues have become an attractive source of mesenchymal stem cells (MSCs). Dental stem cells (DSCs) are not only able to differentiate into adipogenic, chondrogenic and osteogenic lineages, but an increasing amount of research also pointed out their potential applicability in numerous clinical disorders, such as myocardial infarction, neurodegenerative diseases and diabetes. Cell-based therapies are emerging as an alternative treatment option to promote functional recovery in patients suffering from neurological disorders, which are the major cause of death and permanent disability. Together with their multilineage differentiation capacity, their easy availability from extracted third molars makes these stem cells a suitable alternative for bone marrow-derived MSCs. More importantly, DSCs appear to retain their stem cell properties following cryopreservation, a key aspect in their long-term preservation and upscale production. The lecture will address human dental pulp stem cells and their potency to contribute to central and peripheral neuro-regeneration combined with angiogenesis. Human dental pulp stem cells can differentiate into highly differentiated cells including neurons and glial cells. In the peripheral nervous system these glial cells play a crucial role in reinnervation and tissue repair. Application of dental stem cells in stroke models and in arthritis models will be discussed. New data on the effects of L-PRF (Leucocyte Platelet Enriched Plasma) on tissue regeneration, on dental and neural stem cells and on endothelial cells will be presented.

Tenogenic properties of MSC in inflammatory environment

J. Burk1,2

Tenogenic differentiation of multipotent mesenchymal stromal cells (MSC) occurs in response to physical and biochemical stimulation by tendon extracellular matrix and mechanical loading. However, there is no evidence that tenogenic differentiation contributes to the beneficial effects of MSC observed in tendon healing. The aim of this study was to investigate whether tenogenic properties of MSC are affected by conditions mimicking a pathophysiological tendon lesion environment. A three-dimensional dynamic co-culture model was established, using decellularized tendon matrices seeded with equine adipose-derived MSC, which were subjected to cyclic mechanical stretching and co-culture with peripheral blood leukocytes. In addition, standardized inflammatory conditions were investigated using the pro-inflammatory cytokines IL-1β and TNF-α as cell culture supplements. The attachment and integration of MSC into the tendon matrix was less effective in inflammatory conditions. The expression of the extracellular matrix components collagen I, collagen III, decorin and tenascin-C remained widely unaffected, but inflammatory conditions still impacted on musculoskeletal gene expression. The pro-inflammatory cytokines induced a downregulation of scleraxis, smad8 and osteopontin. These changes were observed in a similar manner in co-culture with leukocytes, possibly due to enhanced IL-1 synthesis by monocytes in the co-cultures. This study demonstrates that inflammation interferes with the tenogenic differentiation potential of MSC. On that basis, it is questionable whether MSC would differentiate into tenocytes when implanted in tendon lesions. Modulatory mechanisms may therefore be more important in this context.

Cardiosphere-derived cells for allogeneic stem cell therapy in canine dilated cardiomyopathy
J. Dudhia
Presenting Author: Jay Dudhia, jdudhia@rvc.ac.uk
1Department of Clinical Sciences and Services, Royal Veterinary College, University of London, United Kingdom

Non-ischemic dilated cardiomyopathy (DCM) is the second most common cardiac disease of dogs, resulting in congestive heart failure or malignant arrhythmia causing sudden cardiac death. An underlying genetic basis has been proposed in a number of breeds, including the Doberman and Boxer with a cumulative prevalence in European Dobermans >8 years of age of 44% [1]. As treatment options are limited, there is interest in using cardiac stem cells. Cardiosphere-derived cells (CDCs) are an adult cardiac progenitor cell population that can be derived in large numbers from myocardial biopsies. However, for therapeutic use allogeneic CDCs would be a practical solution which also avoid obtaining cells from unhealthy donors. Although mesenchymal stem cells (MSCs) have been shown to induce an immune-tolerant phenotype in recipients from unrelated donors, they are inferior to CDCs in their cardiac regenerative capability and it is currently unknown if canine CDCs possess a similar immune-privileged status. Our aim therefore was to characterise the phenotype of canine CDCs and to assess their immune-regulatory status in in vitro assays. CDCs, MSCs and lymph node cells (LNCs) were obtained from five dogs immediately post-mortem with owners’ consent and University ethical approval. These cells were isolated as previously published [2] and characterised for colony formation, self-renewal and multipotency. All dogs in the study were heterozygous for both DLA-88 and DRB-1 and varied in haplotype and cells derived from them were assessed for MHC antigens by flow cytometry. Mixed lymphocyte reactions (MLR) incorporating responder LNCs and allogeneic stimulator CDCs or MSCs were performed to assess proliferation [3]. Canine CDCs demonstrated the ability to self renew, form clonal colonies and commit to multiple lineages (myocardial, endothelial and smooth muscle). In MLR assays, CDCs did not induce significant proliferation in responder LNCs when compared to non-stimulated LNCs. This lack of response was confirmed across multiple donor and responder cells with mismatched MHC I and II haplotypes. Interestingly, allogeneic MSCs stimulated a response in LNCs when compared to non-stimulated cell LNCs. These results demonstrate that CDCs do not produce an immunological response in an in vitro model of transplant immune-reactivity suggesting that CDCs possess immune-privileged status and have the potential for their safe use in allogeneic treatment for canine DCM. Further, exploiting naturally occurring non-ischaemic myocardial diseases in dogs, which exhibit close analogy to an equivalent human condition, can act as an essential bridge between discoveries identified in rodent models and achievable clinical therapies.

The immune system is the first responder to trauma and foreign bodies such as biomaterials, yet this response and its capacity to orchestrate tissue repair has not be leveraged in tissue engineering. Biomaterials can be engineered with exquisite control over physical properties and can present an array of spatially controlled biological cues. Until now, these scaffolds have directly targeted stem cells, vascular development, and differentiated cells to stimulate tissue formation or wound healing. Translating tissue engineering technologies to the clinic for multiple clinical applications, we discovered unexpected responses from the adaptive immune system. We profiled in depth the immunological response to the wound environment in combination with biological and synthetic scaffolds. The adaptive immune system, specifically T_H2 T cells, were required for scaffold stimulation of wound repair [1]. We also characterized the tissue immune environment in non-healing wounds and materials that develop a fibrotic capsule and discovered the role of senescent cells [2] and interleukin (IL)-17. Single cell analysis of specific immune populations in the biomaterial response is providing even more resolution of the immune environment around implants and introduces new therapeutic targets. The implications of a pro-regenerative environment on tumor development and the efficacy of immunotherapies will be discussed [3]. Finally, results from clinical trials validating the immune responses associated with tissue repair will be presented. Ultimately, targeting the immune system represents a paradigm shift for the field and will help to realize the promise of regenerative medicine and smart materials.

1PreComb Therapeutics AG, Wädenswil, Switzerland 2Competence Center Tissue Engineering for Drug Discovery (TEDD), ZHAW, Wädenswil

3D tissue models for efficacy and safety testing have an inherent potential to not only improve in vitro biology but more importantly drug development. However, harmonized validation of these advanced in vitro models throughout the discovery and developmental process is required to unlock the full potential of these high potential technologies and design knowledge-driven novel drug development concepts. Already decades ago 3D cell culture technologies have been postulated to become biology’s new dimension changing the way how in vitro research is being accomplished. However, the integration of advanced in vitro models took much longer than anticipated despite the fact that it is agreed within the research community that 3D models reflect more closely the biology of an in vivo tissue or organ. Only over the past 10 years, physiological more relevant models have gained significant momentum in research, especially in drug discovery and development. The expectations are high that by creating more physiological conditions to screening models as well as for safety testing the development of drugs could be performed more efficient than in the past, which basically means an accelerated process with reduced failure rates. However, how realistic is this considering more than 50 years of drug discovery and development incorporating major technological advances on genetic, proteomic and phenotypic level without significant advances on the average success rates of new drug entities with some outstanding years over the past decades? One should think that if the biology of the models are closer to the in vivo biology they should be more translational reducing the gap between in vitro human response and in vivo patient response. However, it has been shown many times that the individual models are much better than current state of the art, but the difficult part is to demonstrate that a process which takes more than ten years can benefit from 3D technologies [1].

Combining bio-fabrication and guided self-organization of vascular cells to engineer complex vascular networks in engineered tissues

J. Rouwkema¹

Presenting Author: Jeroen Rouwkema, j.rouwkema@utwente.nl

¹Department of Biomechanical Engineering, Technical Medical Centre, University of Twente, Enschede, The Netherlands

Optimally engineered tissues will often need to contain a vascular network; either to supply the cells in the tissue with nutrients after implantation, or to ensure a physiological tissue response when the tissue is used as a screening platform [1]. Especially when the tissue is engineered for implantation purposes, this network needs to be properly organized, including macro-vascular structures but also micro-vascular capillaries, to accommodate a functional connection with the vasculature of the patient. Over the past years, multiple approaches have been developed to include vascular networks in engineered tissues. Under the right conditions, the addition of vascular cells within tissue constructs leads to the formation of vascular networks. However, these networks are generally randomly organized and mainly consist of microvascular structures. On the other hand, bio-fabrication approaches can be used to fabricate vascular networks with a tightly controlled and designable organization. However, resolution is often insufficient to include capillary structures and the organization can be lost over time due to tissue remodeling. In order to achieve multiscale organized vascular networks, we are developing a 3D embedded bio-printing approach to spatially control the presence of vascular cells within tissue analogues. This can be seen as a starting situation which will remodel and mature over time. To further guide the organization of the vascular network over multiple scales, both chemical and mechanical cues are included. With this approach, our aim is to control tissue remodeling and maturation, resulting in a vascular network that resembles a vascular tree.

Whereas autologous bone grafts contain all elements for effective bone regeneration (i.e. the appropriate extracellular matrix, cells, and signals), their limited clinical availability and cumbersome harvest urge for (synthetic/allogenic/xenogenic) alternatives with reliable efficacy. Major efforts in the field of biomaterials have resulted in the clinical availability of multiple biomaterials for bone regenerative therapy. Although several of these biomaterials allow direct bone bonding (i.e. bioactive properties) and bone growth over their surface (i.e. osteoconductive properties), the capacity of these biomaterials to induce de novo bone formation is largely lacking. Only few biomaterials have shown such osteoinductive properties [1], but the mechanistic fundamentals of this phenomenon remain elusive. The classic osteoinduction has been described decades ago by Urist, which was caused by bone morphogenetic protein 2 (BMP2). This protein is capable of binding specific receptors on the surface of mesenchymal stromal cells (MSCs), which induces an intracellular signaling cascade resulting in osteogenic differentiation of the uncommitted adult stem cell. Consequently, recombinant DNA technologies has propelled the clinical availability and use of this protein to boost bone formation. However, the cost and supraphysiological amounts of BMP2 required for effective bone formation have tempered its application. Alternatively, de novo bone formation has been shown upon ectopic implantation of calcium phosphate ceramics, for which surface structure appears crucial and related to the formation osteoclastic cells [2]. Strikingly, the application of MSCs for the preparation of cell-based constructs has shown that influx of inflammatory cells and osteoclastogenesis precedes bone formation [3]. Based on these findings and the general knowledge on the interactions between osteoclasts and osteoblasts during bone remodeling, we reasoned that osteoclasts are of pivotal importance in new bone formation. As such, our efforts focused on both the role of biomaterial surface properties on osteoclastogenesis by macrophage precursors, the morphological characteristics of formed osteoclasts, and the functional coupling of these osteoclasts with osteogenic differentiation by MSCs [4]. Further, we challenged the concept of cell-based construct formation by using osteoclasts rather than osteoblasts as the cells of choice in an ectopic implantation model. The data obtained from these studies will revolutionize the traditional concept of osteoinduction and shed light on the elucidation of the mechanism responsible for de novo bone formation.

INSERM UMRS 1229, Regenerative Medicine and Sketeton (RMeS), Université de Nantes & Nantes University Hospital, PHU 4-OTONN, Nantes, France

Intervertebral disc (IVD) is a fibrocartilaginous tissue that grossly consists of a peripheral network of type 1 collagen fibers (namely Annulus fibrosus, AF), which surrounds a highly hydrated gel (namely Nucleus pulposus, NP) rich in type 2 collagen and proteoglycans. IVD degeneration is one of the major causes of low back pain (LBP). Currently, LBP is primarily managed by pharmacological treatments and if unsuccessful by surgical procedures (spine fusion or arthroplasty) that are reserved for severe debilitating LBP. To clinically address LBP earlier in the degenerative cascade of IVD, biology-inspired regenerative strategies could offer less invasive and etiological alternatives to spinal reconstructive surgery. We will first share our view of the mesenchymal stromal cells (MSC)-based therapeutic approaches that have been preclinically developed and, for some of them, clinically transferred in patients with discogenic LBP. Then, we will comment on the recent biomaterial-assisted MSC therapies that recently enter the preclinical and clinical scene of IVD regeneration. Finally, we will share with you our REMEDIV project that aims at developing an injectable NP substitute containing bioactive stem cells-derived IVD cells within a hydrated biomaterial that could be percutaneously transplanted into degenerated IVDs. Finally, we will consider our ability to transplant stem cells-derived IVD cells using a self-setting hydrogel in various animal models. Whether this concept could open new therapeutic windows in the management of discogenic low back pain will finally be discussed.
Injectable thermogels for medical applications
J.D. Ding¹
Presenting Author: Jiandong Ding, jdding1@fudan.edu.cn

Injectable hydrogels are very useful in drug delivery, tissue engineering and regenerative medicine. Compared to chemically crosslinked hydrogels, physical hydrogels formed at body temperature after injection is in particular appropriate for various medical applications. Herein, we report a physical hydrogellable system based on block copolymers composed of hydrophilic poly(ethylene glycol) (PEG) and hydrophobic yet biodegradable polyester such as poly(lactide-co-glycolide) (PLGA).[1-3] We synthesized the block copolymer via ring-opening polymerization of lactide and glycolide initiated by the hydroxyl end groups of PEG. Under appropriate composition, the triblock copolymer PLGA-PEG-PLGA can well be dissolved in water at relatively low temperatures (room temperature or below). The solution is injectable at room temperature, and spontaneously gelled at body temperature. We investigated the underlying mechanism of the physical gelation and revealed that the hydrophobic channel between the semi-bald micelles served as the physical crosslinking points upon heating. We introduced arginine-glycine-aspartate (RGD) peptides into either the PEG block or the PLGA block. While modification of both blocks can enhance cell adhesion of the hydrogel, the immobilizing site in the PEG block was found to be more efficient. Besides potential application of tissue engineering, we have also tried other medical applications of the hydrogels without RGD modification. The hydrogels were confirmed to prevent post-operative adhesion. The mixing with free RGD peptides was found to even further enhance the antiadhesion effect. Such a system with sol-gel transition affords also an excellent platform to encapsulate various drugs.

Design of biomaterials with micro/nano-structure for regulating cell behavior and tissue engineering
J. Chang1
Presenting Author: Jiang Chang, jchang@mail.sic.ac.cn
1Shanghai Institute of Ceramics, Chinese Academy of Sciences, Shanghai 200050 China

The micro/nano-surface structure/topography has been found to affect cellular behavior. However, it is still not fully understood the mechanisms of the structural effect on stem cell differentiation and tissue engineering. In particular, the difference of micro and nano structures and the combination of micro and nano structure on tissue regeneration need to be explored. Therefore, we have developed techniques to fabricate biomaterials with micro/nano structure and investigated activity of the surface structure on stimulating stem cell behavior in vitro, and the activity to enhance tissue regeneration in vivo. Our study demonstrates that both micro and nano structure have activity to stimulate cell behavior by activating signaling pathways related to tissue regeneration. The activation mechanisms of micro and nano structures may be different, and the combination of micro and nano structure revealed further enhanced activity as compared to the single structure type. Our results suggest that both micro and nano structure need to be considered in designing biomaterials for tissue regeneration applications.

From idea to first-in-human trials: Collagen scaffolds for spinal cord repair
J. Dai

Presenting Author: Jianwu Dai, jwdai@genetics.ac.cn
1Center for Regenerative Medicine, Institute of Genetics and Developmental Biology, Chinese Academy of Sciences, Beijing, China.

Spinal cord injury (SCI) is a devastating injury resulting in changes in the spinal cord's motor, sensory, or autonomic functions. Following SCI, an inhibitory environment develops at the injury site to inhibit neural regeneration. We have developed a functional biomaterial consisting of collagen scaffolds (NeuroRegen scaffolds) and biologically active molecules (neurotrophic factor or the antagonists to myelin-associated inhibitor), and stem cells to build a nerve regeneration microenvironment. Specifically, (1) the linear ordered collagen based NeuroRegen scaffold was developed to guide the neural regeneration along its fibers and decrease the formation of glial scars, (2) collagen binding neurotrophic factors were incorporated into the scaffolds to promote neuronal survival and neural fiber regeneration, (3) antagonists to myelin-associated inhibitors were added to the scaffold to direct the neuronal differentiation of neural stem cells at the injury site, (4) Mesenchymal stem cells (MSCs) were also added to the scaffold to reduce the acute inflammatory response due to SCI (figure 1)[1]. These strategies were found to promote neural regeneration and functional recovery in SCI animals. NeuroRegen scaffolds with stem cells are in the clinical study of spinal cord injury repair for over 3 years with over 80 patients enrolled [2][3].

Figure 1: Neuro regenerative microenvironment constructed with functional biomaterials. (a) Collagen-binding biologically active molecules or antagonists were produced, which could be retained at the lesion site in a predetermined spatial arrangement. (b) Collagen-binding cell recognition molecules can be incorporated in biomaterials to capture target cells. Bottom-up layer-by-layer assembly technology to process nanostructured multifunctional biomaterials across multiple length scales for tissue engineering and regenerative medicine strategies
J. Borges

Presenting Author: João Borges, joaoborges@ua.pt
Department of Chemistry, CICECO – Aveiro Institute of Materials, University of Aveiro, Portugal

Over the past decades, scientists have been inspired by fascinating biological systems to develop biomaterial scaffolds aimed at recreating the structural features and functional behavior of native extracellular matrix (ECM) [1]. Natural-origin polymeric materials, including polysaccharides and proteins have shown to be highly promising in emulating ECM features and addressing tissue engineering and regenerative medicine (TERM) strategies owing to their similarities with the ECM, typically good biological performance and high chemical versatility. Despite very promising, natural origin polymers per se often show limited bioactivity, stimuli-responsiveness, and poor mechanical properties, thus extensively limiting their applications, including their capability to support and guide cell fate. Toward this goal, synthetic and biological building blocks have been extensively explored and combined as structural building blocks for the assembly of a wide variety of bioinspired functional architectures with emerging applications in the TERM field. However, most of the developed systems still lack control in thickness and composition, and the functional dynamic nature and structural complexity found in the natural systems. Hence, there is the need for advancing current TERM strategies by resorting to bottom-up assembly methodologies that could finely tune the physicochemical, mechanical, and biological properties of the assembled materials at the molecular level. Among them, the Layer-by-Layer (LbL) assembly technology has emerged as a powerful strategy to achieve surface modification and functionalization, as well as to investigate and regulate the cell functions in physiologically relevant conditions owing to its key enabling features. In particular, it has proved to be a simple, inexpensive, yet robust and highly versatile methodology to fabricate highly organized, robust and functional nanostructured films on virtually any kind of surface, from simple 2D flat platforms to more convoluted 3D surfaces. Such structures are engineered with precisely tailored properties and functions at the nanoscale by resorting to an unprecedented choice of materials, including biological materials assembled through a multitude of complementary intermolecular interactions [2]. In this talk, emphasis will be given to the design of ECM-like biomaterials and advanced biomimetic nanostructured multilayered devices for TERM. In particular, the talk will feature recent work of the group on the use of polysaccharides and peptides, and LbL assembly technology to formulate innovative multifunctional and tunable biomaterials with different shapes and internal structure across multiple length scales, from the nano- to the millimetre-scale. The potential of such devices to act as reservoirs of bioactive molecules and stimulate cell-signaling pathways that are critical in regenerative medicine will be discussed.

Compartmentalization of cells and therapeutic molecules into soft polymeric structures for bottom-up tissue engineering strategies

J.F. Mano
Presenting Author: Joao F. Mano, jmano@ua.pt
Department of Chemistry, CICECO — Aveiro Institute of Materials, University of Aveiro, 3810-193 Aveiro, Portugal

Sophisticated strategies have been employed to encapsulate cells and bioactive molecules in micro-sized matrices using distinct biomaterials, to be explored in cell and tissue engineering. Distinct enabling technologies are overviewed that could be used to encapsulate both molecules and cells in geometrically controlled micro-compartments. Using bioinspired strategies, superhydrophobic surfaces can serve as platforms to process basic units of hydrogels in mild conditions, permitting the encapsulation of living cells and other biological cargo with high efficiency. By using spherical templates containing cells followed by adequate coating procedures it is possible to produce liquefied capsules that may entrap viable cells. The presence of solid microparticles with controlled mechanical properties inside such capsules offers adequate surface area for adherent cell attachment increasing the biological performance of these hierarchical systems, while maintain both permeability and injectability. The liquid environment allows for a free-organization in the space of the cells towards the formation of new microtissues. The basic hybrid elements may be assembled towards larger constructs permitting to engineering tissues in a bottom-up approach with a complete control of the biological cargo.
Novel gram-positive bacteria killing cubosomes with high eukaryotic cytocompatibility – Insights into an interesting lesson from nature

Jochen Salber
Presenting Author: Jochen Salber, jochen.salber@hotmail.com
UMC Knappschaftskrankenhaus Bochum GmbH, Hospital of the Ruhr-University Bochum, Clinic of Surgery, Germany

Since the 1970s, an increasing resistance to antimicrobial agents has become a dangerous threat to the global public health. This requires measures and efforts across all sectors of our society. Effective antibiotics and alternative, complementary antimicrobial strategies also called “drug-free” are necessary for the success of major surgery and interventional therapies or implanted mid- and long-term medical devices. In this context, an international and interdisciplinary team of around 10 scientists and clinicians developed core-shell switchable thermoresponsive colloidal particles based on polyurethane grafted poly(N-isopropylacrylamide)-b-poly(ionic liquid) [NHP407-g-p(NIPAM-b-HPIL)] copolymers. With comprehensive analytics e.g. NMR, dynamic light scattering (DLS), Cryo-TEM etc. the chemical and three-dimensional structure of these new amphiphilic copolymers could be revealed. Cryo-TEM images manifested a cubosome structure. Antimicrobial susceptibility was determined by the broth microdilution method and cytocompatibility evaluation was done on the fibroblast L929 cell line by the Multiplex assay. NHP407-g-p(NIPAM-b-HPIL) cubosomes induced a strong bactericidal effect against non- and antibiotic resistant strains of S. aureus and S. epidermidis. The necessary concentrations were very low. Moreover, the antibacterial effect was induced immediately after the addition of the colloidal dispersion and approximately 99% of S. aureus were killed just within 90 minutes by half of the concentration correspondent to the MBC value. Interestingly, high-resolution SEM-focused ion beam (FIB) experiments showed, that the particles interacted with the bacterial surface only without being incorporated. Biological testing on L929 murine fibroblasts and other eukaryotic cells showed that the system is cytocompatible with concentrations around the MBC values.
Monocyte subsets and macrophage polarization in cell migration and tissue remodeling

J. Wojta$^{1,2,3}$

Presenting Author: Johann Wojta, johann.wojta@meduniwien.ac.at

$^1$Department of Internal Medicine II, Medical University of Vienna, Vienna, Austria $^2$Core Facilities, Medical University of Vienna, Vienna, Austria $^3$Ludwig Boltzmann Cluster for Cardiovascular Research, Vienna, Austria

Human monocytes can be divided into functionally distinct subsets, based on expression of CD14 and CD16, into classical monocytes (CD14++CD16-), intermediate monocytes (CD14++CD16+) and non-classical monocytes (CD14+CD16++) [1]. The CD16+ subsets are associated with pathologies characterized by a chronic inflammatory state including coronary artery disease [2]. We demonstrated recently that in humans with mild inflammation, the CD16+ subsets express the highest levels of inflammatory cytokines [3]. Macrophages also exhibit distinct functional heterogeneity and plasticity [4]. Exposure to interferon-γ and lipopolysaccharide primes macrophages towards a proinflammatory phenotype, whereas macrophages exposed to interleukin-4 (IL-4) and IL-13 are linked to tissue repair processes [4]. Recently, we showed that proinflammatory human macrophages exhibit significantly higher matrix degradation activity compared to reparative macrophages and that this reduced ability to degrade matrix by reparative macrophages is due to increased expression of plasminogen activator inhibitor-1 [5]. Implications and pathophysiological roles of these subsets of monocytes and macrophages in processes such as cell migration and tissue remodeling will be discussed.

Systemic environment, extracellular vesicles and miRNAs in aging: Impact on cell based therapies?
J. Grillari¹,²

Presenting Author: Johannes Grillari, Johannes.grillari@boku.ac.at
¹Department of Biotechnology, BOKU – University of Natural Resources and Life Sciences Vienna, Austria ²LBI for Experimental and Clinical Traumatology, Vienna, Austria

Cellular senescence has evolved from an in vitro model system to study aging to a multifaceted phenomenon of in vivo importance since senescent cells in vivo have been identified and their removal delays the onset of age-associated diseases in a mouse model system [1]. In order to understand how senescent cells that accumulate within organisms with age negatively impact on organ and tissue function, we have started to characterize miRNAs and RNA modifying proteins that are differentially expressed in early passage versus senescent cells and their functional role in the context of cellular and organismal aging. Thereby, we identified circulating miRNAs as bona fide members of the senescence associated secretory phenotype (SASP) that are transferred from senescent cells to their microenvironment or even the systemic environment. These miRNAs are transported via extracellular vesicles and recipient cells taking them up are altered in their cell fate, including altered osteogenic differentiation of mesenchymal stem cells [2,3]. In summary, we present evidence of the importance of specific miRNAs and extracellular vesicles as their carriers, and highlight their potential use as biomarkers of aging and age-associated diseases like especially osteoporosis, or even as therapeutic tools and targets [4].

Peripheral and central nerve damage has severe consequences for mobility and function and general quality of life long-term. The long-term cost of support for patients with these injuries can be extremely high. The current most successful strategy for peripheral nerve repair is the utilisation of autograft to improve function in for example the hand and/or arm. This has obvious limitations and problems due to the need to harvest tissue. Alternatives such as tubing, to maintain space coupled with gels and growth factors are much less successful. Central nervous system repair options are much more limited and the usual procedure is to wait as a small (but unpredictable) percentage of patients will show some functional recovery. More recently some success has been shown with the injection of stem cells, but these procedures were carried out on highly specific injury types. Thus there is a really need for an implant that may give at least some functional recovery. For a paralysed patient, the recovery of even a small amount of function, to allow independent mobility can be transformative. Over the last few years, we have been working on a number of acellular systems for peripheral and central nerve repair. Initial work(1, 2) centred on the utilization of phosphate glass fibres as scaffolds to directionally drive the growth of neurites and this work showed promising results, particularly in the central nerve repair model. More recently it became apparent that maintenance of space was a critical requirement for an implant and so we have developed a new generation of porous implants to drive the repair process. We will present the strategies utilized and the recent in vivo data obtained our work.

Extracellular matrix derived components as building blocks for tough hydrogels
J. Hilborn1,2
Presenting Author: Jons Hilborn, hilborn@kemi.uu.se
1Polymer Chemistry, Department of Chemistry - Ångström Laboratory, Box 538, 751 21 Uppsala, Sweden 2Department of Bioengineering, School of Engineering, The University of Tokyo, 2-11-16, Yayoi, Bunkyo-ku, Tokyo, 113-8656, Japan

In nature, through evolution tissues have uniquely adapted to the demanding mechanical requirements for diverse biological functions. All tissues, with the exception of blood, have to sustain mechanical load. This strength has allowed various medical treatments to be possible where an open wound in the body after trauma can be closed during surgery, to transplant tissues from one site of the body to another and organ transplantation. Repaired tissues can be held together by sutures, staples or screws (mainly for bones) until body’s own repair processes provide healing orchestrated by the controlled release of signalling molecules. To provide suitable scaffolds for tissue growth hydrogels have successfully been used for repair and regeneration in vivo by delivering cells, drugs or signaling biomolecules.[1] The high water content in hydrogels is, however, accompanied by a poor mechanical strength. To address this, extensive efforts have been devoted to synthesizing tough, ductile hydrogels to meet flexibility and load bearing requirements. While they have enhanced mechanical properties, these synthetic polymer-based hydrogels do not have the biodegradability or favorable cell and tissue interactions as given by our body-own extracellular matrix (ECM) components such as proteins and glycosaminoglycans (GAGs). To evaluate if at all it is possible to fabricate a tough transparent biodegradable hydrogel containing collagen, we have recently successfully chemically functionalised collagen molecules to act as reinforcing filler in a hydrogel matrix to make a toughened gel. We have demonstrated in an earlier study that this chemically modified collagen retains its structural and biochemical properties when compared with unmodified collagen.[2] These collagen-based hydrogels have a modulus of 60MPa, can be extended >300% with full recovery upon unloading. This demonstration serves as a proof of concept that designing for toughness is possible using components that individually has gained regulatory acceptance for specific application.

Potential anticancer therapeutic and antibacterial properties of green synthesized Ag, Au and Ag/Au alloy nanoparticles

J. L. Cholula-Díaz

Presenting Author: Jorge Cholula, jorgeluis.cholula@itesm.mx

1School of Engineering and Sciences, Tecnologico de Monterrey, Av. Eugenio Garza Sada 2501 Sur, 64849 Monterrey, N.L., Mexico

Monometallic silver and gold, and bimetallic silver/gold nanoparticles (Ag-, Au-, and Ag/Au-NPs, respectively) have been object of intense research during the last years, mainly due to their excellent antimicrobial effects, as well as their potential applications in anticancer treatments. The use of bimetallic silver/gold nanosystems are expected to present improved therapeutic efficacy by maintaining the general biocompatibility of gold nanoparticles while decreasing the relatively high toxicity of silver nanoparticles towards healthy cells. Moreover, it is possible to vary systematically their physicochemical properties as a function of the NP composition, especially their optical properties [1]. Nevertheless, with respect to their antibacterial and cytotoxic activity, these do not necessary follow a monotonic NP composition-dependent behavior, but rather, their toxicity depends strongly on the particle size, surface area and surface chemistry of the NP [2,3]. The most common synthesis method is the chemical reduction of silver salt by a reducing agent in the presence of a stabilizing agent. Many reducing agents (hydrazine, N,N-dimethyl-formamide and sodium borohydride) may be associated with potential environmental toxicity as well as biological risks, and they are often difficult to dispose. An alternative to these toxic reagents is the usage of plant extracts and biodegradable natural biopolymers for an eco-friendly synthesis of noble metal NPs. In our research group, we have used starch as reducing and capping agent in the highly reproducible and environmental-friendly synthesis of colloidal mono- and bimetallic Ag/Au alloy NPs. Herein, our experience with the green synthesis and characterization and anticancer, as well as antimicrobial properties of colloidal noble metal nanoparticles will be discussed. Specifically, the determination of the therapeutic potential of colloidal Ag, Au and Ag/Au alloy nanoparticles by evaluating their cytotoxicity on a human breast cancer cell panel and on human melanoma cells will be described. Furthermore, the biocompatibility of the noble metal nanosystems towards human normal cells will be presented. Finally, the antibacterial properties of the Au-containing nanoparticles against antibiotic-resistant bacterial strains will be discussed.

The influence of endotoxin on cellular activities
J. Olijve
Presenting Author: Jos Olijve, jos.oolije@rousselot.com
Rousselot-Gelatin, Ghent, Belgium

Endotoxins are found in the outer membrane of gram-negative bacteria and have profound in vivo responses. They can trigger strong immune responses. They are therefore unwanted contaminants in (bio)materials and their activity must be as low as possible. Hence, FDA defined 2.15-20 EU/medical device or 0.06-0.5 EU/ml as application limits depending on the type of application. Endotoxin received significant less attention during in vitro testing. Effects of endotoxin on various cellular activities have been reported. Levels as low as 0.005 ng/ml selectively silences mesoderm induction during directed differentiation of human embryonic cells [1]. Traces as low as 0.002 ng/ml, significantly alter proliferative response of hematopoietic stem cells [2]. Toll-like receptor 4 (TLR4) is the lipid A inflammatory signal transducer responsible for the TLR4 signal pathway induction [3]. Endotoxin levels in solutions and in use biomaterials must be taken into account when performing in vitro experiments with TLR4 cells. This presentation will give examples of the influence of endotoxin on cellular activities and the critical levels.

Environmentally-friendly coatings with antibacterial properties

J.M. Garcia-Martin

Presenting Author: Jose Miguel Garcia-Martin, josemiguel.garcia.martin@csic.es

1Instituto de Micro y Nanotecnología, IMN-CNM, CSIC (CEI UAM+CSIC), Isaac Newton 8, 28760 Tres Cantos, Madrid, Spain

Orthopedic metal implants improve the quality of life of millions of patients each year. The main problem they present is infection, which depending on the type of device and the patient's health affects 0.5-5% of cases. Our approach to this problem is to use nanostructured coatings to reduce the risk of infection. In short, by magnetron sputtering at oblique incidence [1] we fabricate a coating formed by titanium nanocolumns that develop as the result of atomic shadowing processes in the ballistic deposition regime, see Figure. It is an energy efficient method that can be scaled-up to industry, since it takes place at room temperature in one single step and no chemicals are involved (thus without recycling problems). In a first work, we carried out experiments in vitro with the main pathogen agent in implants, the Gram-positive bacteria Staphylococcus aureus (S.a.): it was demonstrated that the nanocolumns have an antibacterial behavior against S.a. (decreases bacterial adhesion and prevents the formation of the biofilm) without affecting the biocompatibility (cells that promote bone growth, osteoblasts, do proliferate and retain their mitochondrial activity) [2]. Recently, a stay funded by the Fulbright Commission at the Nanomedicine Laboratory of Northeastern University (Boston, USA) has made possible to broaden the scope and impact of this research line. On the one hand, we have verified that the antibacterial activity is maintained in a wide range of manufacturing parameters that control the morphological dimensions of the coating, which allows for validating the robustness of this strategy. In fact, it will be shown that some coatings have been fabricated in a semi-industrial equipment, a first approach proving that with feasible modifications, this strategy can be scaled up to large surfaces. On the other hand, we have verified the effectiveness of these nanostructured coatings also against Gram-negative bacteria such as Escherichia coli, which gives them an added value that extends its potential use: this type of bacteria presents a second lipid membrane external to the cell wall that gives them a special resistance to standard treatments with antibiotics. Finally, we have improved the antibacterial activity of these coatings by combining them with other nanostructures. In particular, the decoration of the nanocolumnar coating of titanium with tellurium nanorods by means of a hydrothermal reaction has exhibited enhanced antibacterial properties. This work will be published shortly.

Mimicking the tissue specific extracellular matrix composition by medical electrospinning
J.C. Heikoop¹
Presenting Author: Judith Heikoop, j.heikoop@ime-electrospinning.com
¹IME Medical Electrospinning, Van Dijklaaan 6, 5581 WG Waalre, The Netherlands

Fibre-based scaffolds can be designed to form the basis to engineer living tissue replacement by providing mechanical and structural support and to guide the development of well-organized and functional extracellular matrix. In the regenerative medicine field, electrospinning is often the preferred production technique due to its capability to produce 3-dimensional fibrous ECM lookalike scaffolds with similar nanometer to micrometer length scales using an extensive range of natural and synthetic polymers. The process is highly versatile and tunable, allowing to tailor scaffold properties to fit the demands of the various tissue to be engineered and regenerated. Controlling all the parameters, which create the base of this method’s versatility, has proven to be a challenge, leading to a lot of inconsistencies and batch to batch variability. It's of utmost importance to tightly control and log all relevant parameters. For example, the humidity affects the structural properties of the scaffold on the macro and micro level. Depending on the extend, these structural changes will have a large effect on the mechanical and biological properties of the scaffolds. Furthermore, during the production of fiber-based scaffolds, it is often assumed that a x-amount of polymer feed will result in a defined y-thickness. The really achieved thickness of fibrous scaffolds is normally measured afterwards at the end of the production line, often even in a destructive manner. In electrospinning especially for 3D shapes this assumption can lead to large batch to batch variation. Contactless thickness measurement technology offers the ability to accurately measure the thickness during production also at high fiber collection speeds and allows producing each batch to the desired scaffold thickness to micrometer level. Using multiple measurement locations, each scaffold obtains critical thickness quality checkpoints. This also makes backwards process alterations after final measurement obsolete. Keeping a tight control of the entire production process, also including electric charges combined with real time thickness monitoring, is the approach to drastically reduce variability of fiber-based scaffolds between and within a batch. Furthermore, this is also minimizing waste during the production process and is therefore a prerequisite for scaling a research process to an economically viable manufacturing process. Tightly controlled Medical Electrospinning will allow for the translation of promising research outcomes into the design and development of scaffolds with well-defined features such as porosity and fiber diameter to promote regeneration of the natural structures of the extracellular matrix in a variety of tissues.

3D printable hydrogel-bioinks: Rheological implications and the importance of controlled network formation
J. Groll
Presenting Author: Jürgen Groll, juergen.groll@fmz.uni-wuerzburg.de
Bavarian Polymer Institute, Julius-Maximilians University of Würzburg, Würzburg, Germany

Biofabrication is a young and dynamically evolving field of research [1]. It aims at the automated generation of hierarchical tissue-like structures from cells and materials through Bioprinting or Bioassembly. This approach has the potential to overcome a number of classical challenges relating to organization, personalized shape and mechanical integrity of generated constructs. Although this has allowed achieving some remarkable successes, it has recently become evident that the lack of variety in printable hydrogel systems is one major drawback for the complete field [2]. In order to be suitable for Biofabrication, hydrogels have to comply with a number of prerequisites with regards to rheological behavior and especially stabilization of the printed structure instantly after printing, while at the same time allowing the cells to proliferate. This contribution will present some of our recent work in this field, starting with a method to assess bioink printability [3]. It will then introduce thiol-ene cross-linking as alternative to the often used free radical polymerization to stabilize printed hydrogel structures with better control over network characteristics [4]. This enables the control over nanoparticle migration in and release from printed hydrogel constructs [5] and can be transferred to gelatin as one of the most widely applied bioink systems [6].

Programming of macrophages as the immunomodulatory approach in implantation

J. Kzhyshkowska¹²,
Presenting Author: Julia Kzhyshkowska, julia.kzhyshkowska@medma.uni-heidelberg.de
¹Institute of Transfusion Medicine and Immunology, Medical Faculty Mannheim, Heidelberg University; German Red Cross Blood Service Baden-Württemberg–Hessen, Germany

Implants, transplants, and implantable biomedical devices are mainstream solutions for a wide variety of human pathologies. One of the persistent problems around nondegradable metallic and polymeric implants is failure of macrophages to resolve the inflammation and their tendency to stay in a state, named "frustrated phagocytosis". During the initial phase, proinflammatory macrophages induce acute reactions to trauma and foreign materials, whereas tolerogenic anti-inflammatory macrophages control resolution of inflammation and induce the subsequent healing stage. However, implanted materials can induce a mixed pro/anti-inflammatory phenotype, supporting chronic inflammatory reactions accompanied by microbial contamination and resulting in implant failure. Titanium and titanium alloys have been successfully used in orthopedics, dentistry, cardiology and otorhinolaryngology. However, up to 20% of implants fail due to the development of various complications. We have established the ex vivo model system for the analysis of human primary macrophage responses to the porous and polished titanium surface. Using systems immunology approach we have identified the detrimental responses of human macrophages that included extensive expression of tissue-destroying matrix metalloproteinases, pro-inflammatory cytokines and chitinase-like proteins. The creation of a long-term anti-inflammatory microenvironment around implants and artificial tissues can facilitate their integration. Macrophages are highly plastic cells that define the tissue reactions on the implanted material. Local control of macrophage phenotype by long-term fixation of their healing activities and suppression of inflammatory reactions are required to improve implant acceptance. In order to develop the therapeutic strategy to overcome the chronic inflammatory reactions to titanium we have developed the cytokine cocktail consisting of IL4/IL10/TGFβ1 (M2Ct) that induced long-term anti-inflammatory and pro-healing phenotype in human primary monocyte-derived macrophages. We used the self-standing, transferable gelatin/tyraminated hyaluronic acid based thin films for the controlled release of anti-inflammatory cytokine combinations and demonstrated to maintain the favorable M2-like macrophage phenotype with low responsiveness to pro-inflammatory stimuli. Such self-standing release systems can be used for prolonged local control of macrophage phenotype upon implantation factors.

3D printed bouncy hybrids for cartilage regeneration
J.R. Jones
Presenting Author: Julian RJones, julian.r.jones@imperial.ac.uk
1Department of Materials, Imperial College London, South Kensington Campus, London, UK

Clinicians need bioactive materials that can share load with host tissue (bone and cartilage) and provide a suitable temporary template (scaffold) for tissue regeneration before they biodegrade at a controlled rate. Orthopedic surgeons also need devices that can replace the articular surface of cartilage, then regenerate the cartilage to replace the device, all while recruiting cells from the underlying bone marrow. Such devices do not yet available, but they could be, using our new hybrid biomaterials. Hybrids have nanoscale co-networks of inorganic glass and organic components, e.g. sol-gel silica and biodegradable polymers. We now have hybrids that can “bounce” and self-heal1. The hybrids are ideal for 3-D printing inks, which can yield bespoke scaffold architectures. Osteochondral devices can now be 3D printed that stimulate articular cartilage production and also provide the bearing surface with tribology similar to native cartilage, e.g. coefficient of friction tested against living collagen. Mechanical properties and degradation rate are determined by the amount of polymer and degree of cross-linking. Self-healing is due to polymer chain mobility and hydrogen bonds allowing crack bridging1. When our hybrids are printed to have 200 μm pore channels, they provoke chondrocytes to produce type II collagen matrix, Sox9 and Aggrecan. Importantly, they do not produce type or type X collagen1. Bone marrow stem cells showed similar results. Use of star polymers enables development of hybrids that degrade under action of enzymes2. Therapeutic on release from the scaffolds can be achieved by incorporating strontium for enhanced osteogenesis3,4.

Figure 1: Schematic of a hybrid made with a star polymer with a biodegradable core; a 3D printed hybrid scaffold; stress strain curves comparing star polymer hybrids with polymers of different architectures (random v linear branched v star); Col II and Sox9 production from chondrocytes on 3D printed hybrids of specific architectures.

The ability of perivascular-derived mesenchymal stromal cells (MSCs) to sense and respond to variations in nanoscale extracellular matrix (ECM) composition and changes in mechanics of their local microenvironment is crucial to their survival and function as reparative cells within all tissues. Our investigations have confirmed that by mimicking these biophysical and biochemical cues in vitro, variations in matrix mechanics, ligand type and nano-spatial organization of adhesive ligands can not only invoke, but be deterministic of changes in MSC proliferation, migration and differentiation. Most recently, using a range of real-time fluorescent location and FRET-based biosensors, we have probed the dynamics of MSC adhesion to these types of substrates and quantified the subsequent development of tension and regulation of mechano-sensitive signaling pathways, providing new mechanistic insights into the dynamics of MSC mechanosensing and how lateral spacing of adhesive nanodomains drives hMSC fate through biased RhoGTPase signaling. Furthermore, by identifying differentially expressed microRNAs produced by MSCs in response to varying hydrogel stiffness and RhoA activity, or post activation in an injury site, we have most recently shown that modulating these mechanosensitive miRNAs (through targeted delivery) can overcome local ‘soft’ mechanical cues to drive commitment to stiffer tissues (e.g. bone), even when encapsulated in a soft 3D hydrogel, or suppress the creation of ‘stiff’ fibrotic tissue within an injured ‘soft’ tissue. These recent studies provide novel strategies with which to manipulate MSC fate and significantly impact tissue engineering and regenerative medicine applications that focus on their exogenous use or endogenous manipulation.
Natural biomaterials for bone and osteochondral defect repair
K. Alpantaki 1,2

As people grow older musculoskeletal disorders are leading causes of morbidity and disability. Degenerative joint disease, mainly osteoarthritis, and intervertebral disc degeneration are considered the most common reason of chronic pain and disability within adult population. A considerable number of sufferers facing severe pain and activity limitation and seek surgical intervention. Apart from degenerative disorders, osteochondral defects following traumatic events, bone defects caused by complex fractures or tumours removal, delayed union or nonunion, and spinal fusion further conduce to the patients’ reservoir requiring surgical treatment. The subsequent burden in terms of both quality of life and financial cost is enormous and expected to be further increased. Existing treatment options are vastly invasive; they address acute symptoms while they are inadequate in arresting the process of degeneration. The insufficiency of the current methods to address the problem and the increasing prevalence due to the aging population exacerbates the need of novel treatment modalities. Currently, tissue engineering technology based on the fabrication of natural polymers seeded with cells and enriched with growth factors is aiming to provide effective alternative substitutes for bone and cartilage repair. During this presentation, the main findings gained from our in vitro and in vivo studies will be discussed. We have evaluated the potential of crosslinked chitosan/gelatin (CS:Gel) scaffolds cultured with pre-osteoblastic cells and human bone marrow mesenchymal stem cells (BM-MSCs) to promote osteogenic differentiation. The scaffolds supported the formation of extracellular matrix, while fibroblasts surrounding the porous scaffold produce collagen with minimal inflammatory reaction in vivo. Additionally, we have evaluated the potential of crosslinked chitosan/alginate (Ch/Alg) porous scaffolds to promote the proliferation and fibro/chondrogenic differentiation of human nucleus pulposus cells indicating a potential use in intervertebral disc regeneration. Our findings provide evidence that natural biomaterials represent a promising strategy for tissue engineering for bone and osteochondral defects.
Harnessing the inflammatory response for tissue regeneration
K.L. Spiller

Presenting Author: Kara L. Spiller, PhD, spiller@drexel.edu

1Biomaterials and Regenerative Medicine Laboratory, School of Biomedical Engineering, Science, and Health Systems, Drexel University, Philadelphia, PA, USA

The inflammatory response plays a major role in the body’s response to injury, disease, or implantation of a biomaterial. When the inflammatory response functions normally, it can be a powerful force that promotes tissue repair and regeneration, but when it goes awry, disease takes hold and healing is impaired. Our is to understand the mechanisms by which the inflammatory response orchestrates successful tissue regeneration and to develop novel biomaterial strategies that apply these principles to situations in which tissue regeneration is impaired. In particular, we focus on the behavior of the macrophage, which can rapidly change behavior in response to environmental stimuli to promote inflammation, vascularization, tissue deposition, or remodeling. Through their dynamic phenotypic changes, macrophages function as major regulators of healing. In this talk, we will focus on our work to develop novel affinity-based drug delivery strategies that harness macrophage behavior to promote tissue regeneration and healing, with a particular emphasis on angiogenesis.

Nidogen-1 improves cardiac function post myocardial infarction via synergistic angiogenesis, neurogenesis, scar modulation and immune response
K. Schenke-Layland 1,2,3
Presenting Author: Katja Schenke-Layland, katja.schenke-layland@uni-tuebingen.de
1Department of Women’s Health, Research Institute for Women’s Health, Eberhard Karls University Tuebingen, Tuebingen, Germany 2Natural and Medical Sciences Institute (NMI) at the University of Tübingen, Reutlingen, Germany 3Department of Medicine, Cardiovascular Research Laboratories, David Geffen School of Medicine at UCLA, Los Angeles, CA, USA

Myocardial infarction (MI) is a major cause of morbidity and mortality worldwide with the need for safe and scalable cardio-regenerative and reparative therapies. Our study of the extracellular matrix (ECM) during cardiogenesis within differentiating pluripotent stem cells and human fetal cardiac tissues identified a new therapeutic candidate, nidogen-1 (NID1), with a cardioprotective function in the post MI setting. In vitro cytotoxicity, endotoxin and immunological studies of recombinantly produced human NID1 verified its safety for in vivo use and potential for regenerative immune system response. Intra-myocardial injections of a NID1-functionalized hydrogel were tested in a mouse MI and reperfusion model. Echocardiography revealed a significant increase of ejection fraction and fractional shortening in NID1-treated animals when compared with controls. This important functional improvement was attributed to cardioprotection, a significant increase in vascular and neuronal cells in the infarct area, and a significant reduction in scar size. Our study demonstrates the efficacy of NID1 as a potential therapeutic candidate post MI, based on a unique synergy of cardiac protection, angiogenesis, neurogenesis and scar modulation.

Benchtop grafting of protein-polymer bioconjugates in the absence of external deoxygenation – Synthesis and applications
K. Velonia
Presenting Author: Kelly Velonia, velonia@materials.uoc.gr
Department of Materials Science and Technology, University of Crete, Heraklion, Crete, Greece

Hierarchical architectures are ubiquitous in biological systems where multifunctional materials are produced in situ, under ambient conditions and, through ecologically balanced processes. Synthesized to mimic natural superstructures, amphiphilic protein-polymer conjugates, exhibit enormous potential in nanotechnology. Their synthesis conventionally requires stringent anaerobic conditions and specialized equipment, limiting potential applications. Based on the recent development of oxygen tolerant approaches aiming to simplify polymerization protocols in materials science, herein we report a novel, simple reaction protocol for quantitative synthesis of protein-polymer bioconjugates in the absence of any external additives. We will discuss how, by simply adjusting the headspace of the reaction vessel, we overcame the challenges of conventional synthesis and developed a synthetic approach that offers robustness and versatility for the synthesis of a variety of protein polymer bioconjugates. Different strategies employing several reversible-deactivation radical polymerization (RDRP) approaches leading to multifunctional and responsive polymer-protein conjugates will be presented. The intriguing molecular properties and assembling architectures observed in a variety of such biopolymers together with promising applications of these novel synthetic biomaterials in drug delivery will be presented.
Biomaterial-driven in situ transplantation of mesenchymal stromal cells for myocardial repair
K. Suzuki,
Presenting Author; Ken Suzuki, ken.suzuki@qmul.ac.uk
William Harvey Research Institute, Barts and The London School of Medicine, Queen Mary University of London, United Kingdom

Myocardial infarction (MI) remains a major cause of human death and disability. Although the recent progress in recanalization therapies have significantly improved the mortality of acute MI, this has resulted in an increase of patients suffering post-MI chronic heart failure. The hearts post-MI frequently undergo pathological cellular and molecular remodelling, and the heart function becomes increasingly deteriorated with significant cardiac dilatation. As a result, many patients develop severe congestive heart failure. Thus, development of more effective, widely-available new treatments is urgent requirement. Myocardial repair and/or regeneration by means of transplantation of stem/progenitor cells is a promising new approach for the treatment of MI. Transplantation of adult (tissue-resident) stem cells (i.e. mesenchymal stromal cells, bone marrow stem cells, cardiac resident stem cells) can offer the repair of damaged myocardium by paracrine secretion, whilst transplantation of pluripotent stem cells (i.e. induced pluripotent stem cells, embryonic stem cells) may achieve myocardial regeneration through their cardiomyogenic differentiation. Based on encouraging pre-clinical data, various protocols of this approach have been or are being tested in clinical trials. However, to date, the overall results of the previous clinical trials are rather disappointing; therapeutic benefits observed are not as substantial as expected (though positive absolutely), requiring further refinement of the protocol. One of the main issues associated with this approach is the suboptimal cell-delivery route. Current methods are intracoronary and intramyocardial injection. However, these methods are known to result in limited initial retention, insufficient survival and thereby poor engraftment of donor cells, profoundly limiting the therapeutic efficacy. These injection methods also carry a risk of arrhythmia occurrence and coronary embolism. More recently, biomaterial-driven epicardial placement has been proposed as an alternative, safer and more effective route. We have reported the utility of epicardial placement aided with the cell-sheet technique, fibrin sealants, hydrogels, and films [1-3]. These methods can be completed with little invasiveness to the patinates, particularly when applied to patients undergoing open heart surgeries. This lecture will summarize the advantages and disadvantages of these cell-delivery methods and discuss future strategies.

Bioprinting techniques for high throughput tissue modelling
K.W. Dalgarno
Presenting Author: Kenny W. Dalgarno, kenny.dalgarno@ncl.ac.uk
School of Engineering, Newcastle University, Newcastle, UK

Interest in the generation of multi-cellular tissues for disease modelling has been growing steadily over the past few years, with models proposed in the literature for a wide range of diseases. 3D, multicellular micro-tissue models may be developed in the form of co-culture spheroids, organ-on-a-chip type systems, or engineered tissues. The growth in interest has been fuelled by the continued failure of simpler in vitro models to work effectively as pre-clinical predictors of in vivo performance. However, the use of micro-tissues in the development of therapies or in any clinical context has been very limited as many experiments have low numbers of models, with no dilution series, replications, or positive and negative controls. This makes the models slow to develop and validate and low throughput in terms of their ability to provide information on diseases or therapies. The key to enabling the widespread use of micro-tissue models is throughput, as this will allow models to be developed and validated quicker, and then run as high throughput assays once they have been developed. Bioprinting techniques offer an attractive approach to creating initial co-cultures, with the ability to locate cells, fluids, and biomaterials within a wellplate or microfluidic system, but historically the techniques have not been widely adopted for the creation of micro-tissue models as the technologies have reliability and productivity limitations. This presentation will outline developments in bioprinting techniques and bio-ink formulation which overcome these limitations and will describe how the techniques are being applied to high throughput tissue modelling.
Human organs chips for drug development, disease modeling, and more…
K. E. Healy1,2
Presenting Author: Kevin E. Healy, kehealy@berkeley.edu
1Department of Bioengineering 2Department of Materials Science & Engineering, University of California, Berkeley, California, USA

Our work has emphasized creating both healthy and diseased model organ systems, we call microphysiological systems (MPS) or ‘organ chips’, [1-3] to address the costly and inefficient drug discovery process. The average time to develop and launch a new drug is 10-15 years, and costs ~ €5-3b. The poor efficiency and high failure rates are attributed to the heavy reliance on non-human animal models employed during safety and efficacy testing that poorly reflect human disease states. With the discovery of human induced pluripotent stem cells (hiPSC), we can now develop MPS to be used for high content drug screening, disease modelling, and numerous other applications. By combining the genetic background of hiPSC with microfabrication technologies, we can create MPS with appropriate biophysical tissue architecture and “tissue-like” drug gradients that recapitulate minimal human organoids sufficiently to allow accurate prediction of the toxicity of drugs. This presentation will discuss our progress in developing integrated in vitro models of human cardiac and liver tissue based on populations of normal and patient specific hiPSCs differentiated into cardiomyocytes, hepatocytes, or supporting cells. The benefits of our approach include: 1) robust microengineering platforms that control microtissue organization and function; 2) precise delivery of molecules (e.g., drugs) in a computationally predictable manner; 3) ability to model human disease; 4) cost efficient and high content characterization of an integrated multi-organ drug response; and, 5) reduction in use and refinement of animal experiments. While chips featuring single organs can be of great use for both pharmaceutical testing and basic organ-level studies, the huge potential of organ chip technology is revealed by connecting multiple organs on a single chip to create a scalable integrated human system for mechanistic biological studies and devising therapies for common, rare, and difficult to study diseases. This presentation will also address our cardiac-liver integrated MPS to predict drug-drug interactions. Ultimately, the vision of MPS technology is to reduce or eliminate the use of animals in drug discovery, and conduct ‘clinical trials’ in patient-specific organ chips that can accommodate variations in genetics, environment, and lifestyle.

Commercialising university technology
K. Ryan
Presenting Author: Kieran Ryan, kieran.a.ryan@nuigalway.ie
Technology Transfer Office, National University of Ireland Galway, Galway, Ireland

Universities have an obligation to ensure that Intellectual Property (IP) outputs are properly captured and exploited according to various National and European guidelines. There are two main ways which University technology development can take on the road to commercialisation: 1. Licensing the technology to an existing company: A license is permission to do something the granting party (the licensor) has the right to otherwise prohibit. In the context of IP licensing, it is a grant, by the owner of the property, to another (the licensee) of the right to use the IP in question for commercial purposes; 2. Starting a new company: An important university objective is to explore and pursue opportunities for the exploitation of its intellectual property rights. For universities and its inventors, spin out companies often provide an effective means to achieve this objective. A spin out is created when the University creates a new company out of one of its existing departments, institutions or by an inventor. The decision of which path to take is critical and various elements can effect this decision such as the inventors own objectives, the market niche for the technology, the stage of technical development, the potential reward for each option and the types of support structures available. This talk will summarise the main points to consider when deciding on the most appropriate way to commercialise technologies developed in Universities.
Tailor-made 3D tissue models: What works for industry and what does not
L. Suter-Dick
Presenting Author: Laura Suter-Dick, laura.suterdick@fhnw.ch
1Molecular Toxicology, School of Life Sciences, University of Applied Sciences Northwestern Switzerland (FHNW), Muttenz, Switzerland

Tailor-made 3D tissue models, microphysiological systems and organ on a chip are now state of the art devices for the performance of organotypical cell cultures. They can be based on cell lines, primary cells or stem cells (iPS). These systems allow for specific tissues or even organ systems to be construed in vitro. They create a physiologically relevant environment, bridging the gap between in vitro and in vivo models and offering new approaches to research in medicine, biology, and pharmacology [1]. The potential for the implementation of these relatively novel techniques in the industrial context has been widely recognized. On the one-hand side, 3D structures have better physiological properties than planar monolayer cultures. This has been shown to enhance the function and life span of cells in culture. For the liver, for example, hepatocytes grown in 2D quickly differentiate and lose their functional characteristics such as metabolic competence. Hepatocytes grown in 3D, however, can be maintained over longer periods of time and still display metabolic functionality. Complex, 3D systems, also allow to better co-culture several cell types in one system or “microtissue”. As an example, liver microtissues can contain only hepatocytes or a combination of hepatocytes and non-parenchymal cells. This combination allows the in vitro system to be able to mimic more complex events involving inflammatory responses and the process of fibrosis [2]. Tissues with barrier functions such as epithelia and endothelia, that are usually exposed to flow conditions in vivo profit from growing under microfluidic stress that can support cell polarization and cell function. Classical examples are the proximal tubule of the kidney, a common target for drug induced kidney injury [3]. Multiorgan systems or body on a chip are also slowly gaining acceptance in the pharmaceutical industry as they allow the testing of interactions between two or more tissues. Despite the technical and scientific progress, some major hurdles remain for the adoption of such complex systems in pharmaceutical drug development. On the one hand, complex systems are less amenable to automation and high-throughput screening, which limits their applicability in drug discovery. Inherent to their complexity is also a certain degree of variability, which is not welcomed in the drug screening process. The main contribution these systems can make nowadays is the understanding of mechanisms of toxicity and the partial replacement of animal studies in the early phases of drug development. At this point of the drug development process, fewer chemicals are tested and therefore assays of medium throughput and high complexity can be deemed acceptable. However, high standards need to be met in terms of robustness and standardization. Technical issues related to miniaturization of fluidic systems, compound adsorption to chip-material and tubing, issues inherent to flow, and large dead volumes must be kept to a minimum. In addition, appropriate, measurable endpoints must be optimized in terms of sensitivity to detect cellular responses and lead to scientific and regulatory acceptance of the results.

Angiogenic properties of dental pulp stem cells for tissue engineering
L. Muller
Presenting Author: Laurent Muller, laurent.muller@college-de-france.fr
Center for Interdisciplinary Research in Biology (CIRB), CNRS UMR 7241 – INSERM U1050, Collège de France, Paris, France

A limiting step for the success of cell-based therapies is the requirement for rapid blood perfusion deep in the tissue constructs in order to maintain differentiation and support survival of the implanted stem cells. Dental pulp stem cells (DPSC) have been proposed as optimal candidates for tissue regeneration strategies of lesions and injuries in the craniofacial area, in order to regenerate dental pulp as well as bone. DPSC could participate in construct vascularization either directly through their differentiation into endothelial cells, or through paracrine activation of the host vasculature and promotion of angiogenesis. The latter pathway has been the subject of many investigations in order to identify means of increasing the angiogenic potential of DPSC. In this context, hypoxia has been proposed as a major factor that could be used for pre-conditioning of DPSC through the regulation of VEGF release. We have shown that FGF-2 is even more potent through the stimulation of the secretion of both VEGF and HGF by DPSC, since these factors act in synergy for promoting angiogenesis. We indeed demonstrated that a short exposure of DPSC in vitro, prior to implantation, was sufficient for increasing vascularization of the tissue constructs (Gorin et al, 2016). More recently, pre-vascularization strategies based on in vitro generation of micro-vascular networks have been the subject of many studies. We have thus investigated DPSC capacity to promote micro-vascularization of collagen scaffolds and characterized their participation to capillary formation together with their perivascular recruitment and their participation to vessel maturation through the generation of the vascular basement membrane. We also assessed the impact of such in vitro pre-vascularization on perfusion of the tissue construct after implantation in SCID mice.

Elsevier Limited, Oxford, United Kingdom

This session will look at key changes in the publishing landscape including open science and the global increase in publications. The analysis of key publishing data and trends will also be discussed in terms of how this information is driving new types of articles, new ways of sharing content and opportunities to increase diversity and global representation within our journal teams.
Transforming the spleen into a functioning liver in vivo
L. Dong
Presenting Author: Lei Dong, leidong@nju.edu.cn
1State Key Laboratory of Pharmaceutical Biotechnology, School of Life Sciences, Nanjing University

Regenerating human organs remains an unmet medical challenge. Suitable transplants are scarce, while engineered tissues have a long way to go towards clinical use. In our previous study [1], a tumor homogenate-containing hydrogel (THAG), successfully creates an immunosuppressive enclave after transplantation into immunocompetent mice. Xenogeneic cancer cells of different species and tissue origins seeded into THAG survive well without being eliminated or spreading out of the enclave. It suggested that it was possible to harness the unique features of tumor development for tissue transplantation. Here, we demonstrate a different strategy that successfully transformed an existing, functionally dispensable organ to regenerate another, functionally vital one in the body. Specifically, we injected a tumor extraction into the mouse spleen to remodel its tissue structure into an immunosuppressive and pro-regenerative microenvironment. We implanted autologous, allogeneic or xenogeneic liver cells (either primary or immortalized), which survived and proliferated fast in the remodeled spleen, without exerting adverse responses. Notably, the transplanted liver cells exerted typical hepatic functions to rescue the host mice from severe liver damages including 90% hepatectomy. Our approach shows its competence in overcoming the key challenges in tissue regeneration – including insufficient transplants, immune rejection and poor vascularization. It may be ready for translation into new therapies to regenerate large, complex human tissue/organs.

No antibiotics biomaterials functionalization to prevent and fight implants associated infections
L. Rimondini
Presenting Author: Lia Rimondini, lia.rimondini@med.uniupo.it
Department of Health Sciences, Università del Piemonte Orientale, Novara, Italy

Implant-related infections are one of the most common reasons for surgical failure (14-29% of total failures in orthopaedics), in most cases causing severe disability and leading to a significant reduction in the patient’s quality of life. According to the most recent surveys, the mortality rate of patients undergoing primary implant infections ranges from 10 to 18%; moreover, if an infection occurs also in the revised implants, this percentage can double or triple. In most of the cases infections are due to antibiotic resistant biofilm that makes treatment very difficult. Therefore, technologies addressed to prevent biofilm formation onto implants surface, without affecting biocompatible properties, seems to be a promising approach. In the present lecture, not functionalized and functionalized biomaterials with ions, polyphenols, proteins with bacteriostatic properties and “zombies” bacteria will be presented. All these technologies are alternative to antibiotic treatment and especially design to be complaint with tissue regeneration application requirements and to prevent or fight antibiotic resistance.
Creating environments to control biological response
L. Grover,
Presenting Author: Liam M Grover, l.m.grover@bham.ac.uk
University of Birmingham, UK

Cells are highly responsive to local physical and chemical stimulus. As such, controlling local environment can be used as a means to modulate pathological processes or could be used to control tissue growth ex-vivo. In this talk, I will discuss how we are using materials to deliver agents that control the inflammatory microenvironment around a wound to control tissue healing and thereby prevent scarring both in the skin and across the surface of the eye. I will also discuss how we are using materials to create environments that can be used to create organotypic cell cultures to screen for novel therapeutics.
Combining in vitro and in silico models in regenerative medicine: A digital twin for perfusion bioreactor processes
L. Geris¹-³

¹Prometheus, R&D Division for Skeletal Tissue Engineering, KU Leuven, Belgium. ²GIGA In silico medicine, University of Liège, Belgium. ³Biomechanics Section, KU Leuven, Belgium.

INTRODUCTION: One of the major bottlenecks and cost drivers of cell-based therapies at this point is the manufacturing process that all too often is a scaled out version of the cumbersome manual laboratory procedures established during product development. Here, we describe the development of a perfusion bioreactor for cell expansion along with its digital twin, allowing for a precise monitoring and control of the cell culture process.

METHODS: Based on observations made in a suite of experimental results obtained with a pilot version of the perfusion bioreactor set-up, a mechanistic computer model of the neotissue (cells + extracellular matrix) growth was developed [1]. Speed of growth was observed and modeled (in FreeFEM++) to be influenced by local curvature, flow-induced shear stress, oxygen, glucose and lactate concentrations. The different model components were calibrated using in-house experimental data. Predictions on neotissue growth for 2 different triply periodic minimal surfaces were verified in a dedicated experimental set-up. A reduced and reparametrized version of the model was developed (in MATLAB®) by homogenizing over the scaffold volume, allowing for rigorous single- and multiple objective optimization studies to determine bioreactor settings for maximal neotissue growth. A low footprint standalone version of the perfusion bioreactor set-up was developed, including connections for electronic and optical sensors at the chamber in- and outlet for environmental monitoring and control.

RESULTS & DISCUSSION: Model predictions showed enhanced neotissue formation and lactate production for Gyroid compared to Dcup scaffolds. Experimental results were quantified in 3D by contrast enhanced nanoCT imaging, confirming model predictions. The reduced model showed increased neotissue formation for frequent replacement of the bulk of the medium in the bioreactor. Taking into account the cost of culture shifted the optimal settings towards lower replacement frequencies and medium fractions. Online monitoring of oxygen, glucose and lactate is possible in the standalone set-up and will provide, on the one hand, additional experimental read-outs for model credibility building and, on the other hand, the necessary real-world data to allow real-time model-based monitoring and control of the process.

CONCLUSIONS: The simultaneous development of a standalone perfusion bioreactor and its digital twin ultimately will allow for the precise prediction and follow-up of neotissue formation in a 3D perfusion environment, which is an important step towards automation of cell expansion in the context of TE therapies.

Department of Oral Biology, The Goldschleger School of Dental Medicine, Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv 69978, Israel

Molecular self-assembly is a key direction in current nanotechnology based material science fields. In this approach, the physical properties of the formed assemblies are directed by the inherent characteristics of the specific building blocks used. Molecular co-assembly at varied stoichiometry substantially increases the structural and functional diversity of the formed assemblies, thus allowing tuning of both their architecture as well as their physical properties. In particular, building blocks of short peptides and amino acids can form ordered assemblies such as nanotubes, nanospheres and 3D-hydrogels. These assemblies were shown to have unique mechanical, optical, piezoelectric and semiconductive properties. Yet, the control over the physical properties of the structure has remained challenging. For example, controlling nanotube length in solution is difficult, due to the inherent sequential self-assembly mechanism. Another example is the control of 3D-hydrogel scaffold’s physical properties, including mechanical strength, degradation profile and injectability, which are important for tissue engineering applications. [1] Here, in line with polymer chemistry paradigms, we applied a supramolecular polymer co-assembly methodology to modulate the physical properties of peptide nanotubes and hydrogel scaffolds. Utilizing this approach with peptide nanotubes, we achieved narrow nanotube length distribution by adjusting the molecular ratio between the two building blocks; the diphenylalanine assembly unit and its end-capped analogue. In addition, applying a co-assembly approach on hydrogel forming peptides resulted in a synergistic modulation of the mechanical properties, forming extraordinary rigid hydrogels. [2] Furthermore, we designed organic-inorganic scaffold for bone tissue regeneration. [3] This work provides a conceptual framework for the utilization of co-assembly strategies to push the limits of nanostructures physical properties obtained through self-assembly.

3D NephroScreen: High throughput drug-induced nephrotoxicity screening on a proximal tubule-on-a-chip model

L. Gijzen

Presenting Author: Linda Gijzen, l.gijzen@mimetas.com

1MIMETAS BV, J.H. Oortweg 19, NL-2333CH Leiden, The Netherlands, info@mimetas.com, www.mimetas.com

INTRODUCTION: Renal toxicity remains a major issue in clinical trials and stresses the need for more predictive models fit for implementation in early drug development [1]. Here, we describe a perfused, leak-tight renal proximal tubule cell (RPTEC) model cultured within a high throughput microfluidic platform (Mimetas’ OrganoPlate®), along with recent results from a 12-compound nephrotoxicity screen performed within the “NephroTube” CRACK IT consortium in collaboration with sponsors and the NC3Rs.

METHODS: Human RPTEC (SA7K clone, Sigma) were grown against a collagen I ECM in a 3-channel OrganoPlate®, yielding access to both the apical and basal side. Drug-induced toxicity was assessed by exposing kidney tubules to 4 benchmark and 8 blinded compounds with known clinical effects supplied by the sponsors for 24 and 48h. The tightness of the barrier was evaluated by diffusion of a dextran dye from apical to basal compartment. Parallel to this, cell viability with a WST-8 assay and the presence of LDH in the supernatant were assessed. Finally, kidney tubules were lysed, and RNA was extracted for gene expression analysis of acute kidney injury markers.

RESULTS & DISCUSSION: Upon perfusion flow, RPTEC form leak-tight confluent tubular structures against the collagen I ECM in the OrganoPlate®. The NephroScreen revealed significant decreased barrier tightness and cell viability in 7 out of 12 compounds. Furthermore, the release of LDH was significantly increased in 9 out of 12 compounds. An increased expression in HMOX1, TNFα and NGAL was observed in 9, 5 and 7 out of 12 compounds respectively whereas claudin-2 showed a decrease in 6 out the 12. Overall, more effects were observed after 48h in comparison to 24h exposure.

CONCLUSIONS: The kidney-on-a-chip model in the OrganoPlate® provides a promising in vitro renal toxicity tool to answer the desire to provide a better alternative to animal studies in terms of throughput, costs and predictivity and ultimately will be commercialised after further validation.

Biofabrication: A tool set to study biology in 3D with applications in regenerative medicine and in vitro models
L. Moroni
Presenting Author: Lorenzo Moroni, l.moroni@maastrichtuniversity.nl
MERLN Institute for Technology-Inspired Regenerative Medicine, complex tissue regeneration department, Maastricht University, Maastricht, the Netherlands

Organs are complex systems, comprised of different tissues, proteins, and cells, which communicate to coordinate many functions in our bodies. To replicate these structures towards the development of new therapies for tissue and organ repair, as well as for in vitro 3D models to better understand the morphogenetic biological processes that drive organogenesis, more and more advanced technologies are needed. Biofabrication strategies, in particular, are being developed to construct tissues and organs, and impart spatiotemporal control over cell-cell and cell-extracellular matrix communication, often through control over cell and material deposition and placement. Here, we present some of our most recent advancements in biofabrication that enabled the control of cell activity, moving towards enhanced tissue regeneration as well as the possibility to create more complex 3D in vitro models to study biological processes.
Long-term survival of transplanted autologous canine liver organoids in a COMMD1 deficient dog model of metabolic liver disease like Wilson’s disease

L.C. Penning

Presenting Author: Louis C. Penning, L.C.Penning@uu.nl
Department of Clinical Sciences of Companion Animals, Faculty of Veterinary Medicine, Utrecht University, Utrecht, 3584 CM, the Netherlands

The low number of patients suffering from rare diseases hampers research investments. Due to inbreeding in dogs these diseases often occur more frequent and are much more prominent in the animals. In view of the molecular, cell-biological, and clinical similarities, and comparable sizes and life-expectancy, dogs are ideally positioned to play a crucial role as models, especially for rare diseases. Here an example is presented how a naturally occurring genetic mutation in dogs is utilized to create a highly relevant animal model to investigate feasibility of liver stem cell transplantations.

For metabolic liver diseases, liver cell transplantation can be a less invasive alternative to liver transplantation. Primary human hepatocytes have been transplanted in patients with various inborn errors of metabolism. However, hepatocytes do not expand in vitro, are obtained from allogenic livers, and do not persist in the recipient. Adult liver stem cells cultured as organoids are a highly expandable cell source, which can be genetically modified and are a potential attractive alternative for cell transplantations [1]. We have transplanted autologous, gene corrected canine liver organoids in a COMMD1 deficient dog model of copper toxicosis, resembling human Wilson’s disease [2,3]. Liver progenitor cells were obtained from COMMD1 deficient dogs by liver biopsy, lentivirally transduced with the full length canine COMMD1 gene, and expanded to 4.4-9.3x10^8 cells as organoids within 12 weeks. Cells were transplanted back into the same dog by either intrahepatic injections or intraportal delivery. Four dogs were transplanted, one dog served as vehicle control. Liver was sampled before, short term (1 week) and long term (up to two years) after transplantation. Even though the engraftment and repopulation percentages were low, the transplanted and gene-corrected cells survived in the liver for up to two years after transplantation. Liver organoids can be used for gene correction and subsequent autologous cell transplantation. Intraportal transplantation of high cell numbers is safe and technically this procedure can easily be extrapolated to human transplantation. Further research should focus on optimizing hepatic differentiation of organoids and the effect on repopulation and functional recovery. These preclinical studies in long-living large animals are pivotal for the translation of liver organoid transplantations from an experimental setting to human clinical application.

Functional injectable biomaterials for minimally invasive surgery  
L. Ambrosio  
Presenting Author: Luigi Ambrosio, luigi.ambrosio@cnr.it  
Institute of Polymers, Composites and Biomaterials, National Research Council, Viale J.F. Kennedy, 54, Mostra d'Oltremare, Pad.20, 80125 Naples, Italy  

INTRODUCTION: The implementation of a personalised therapy together a less invasive surgery for the restoration of human tissues is becoming an appropriate strategy to mitigate costs of the modern health care system and the maintenance of health and quality of life. The selection of a suitable injectable is often based on material characteristics (including mechanical properties, drug release kinetics and degradation) that serve for the specific treatment function. By a careful selection of materials and processing conditions it is possible to finely control the behaviors from micro to sub-micrometric scale to develop active platforms to support the repair/regeneration of different tissues such bone and intervertebral disc (IVD).

METHODS: Calcium phosphate obtained by sol-gel synthesis combines hydroxyapatite (HA) with other calcium phosphate phases such as dicalcium phosphate (DCP), a precursor of natural HA in bone. Here, a bioactive and osteo-inductive injectable calcium phosphates is prepared by modification of hydroxyapatite with Strontium (Sr) due to its dual mode of action, simultaneously increasing bone formation while decreasing bone resorption. Furthermore, Hyaluronan gels as nucleous substitute were studied. In particular, specific formulation of hyaluronan (HA) polymeric substitute materials HYAFF 120 (an ester of HA), HYADD3 (an amide of HA), and collagen-low molecular weight hyaluronic acid semi-interpenetrating network loaded with gelatin microspheres as a potential material for tissue engineering of the nucleus pulposus (NP) were studied. For in vitro studies BMSCs were seeded on HYADD3. Meanwhile, for in vivo study the gels were injected into the NP of the lumbar spine mini-pigs in which a nucleotomy had been performed.

RESULTS & DISCUSSION: The injectable Sr-containing calcium phosphate bone cement (CPC) presented appropriate radio-opacity and injectability needed for bone filler applications. Moreover, the systems based on strontium modified hydroxyapatite (Sr-HA) at different composition demonstrated also a tunable proliferation and osteogenic differentiation of hMSC. The proposed gels for tissue engineering of the nucleus pulposus (NP) displayed a gel-like behavior, it was easily injectable as demonstrated by suitable tests. Importantly, it supported the growth and chondrogenic differentiation potential of mesenchymal stem cells (MSC) in vitro and in vivo. The properties of the semi-IPN hydrogel were successfully combined with TGF-β3 delivery by gelatin microspheres, which promoted the chondrogenic phenotype. The in vivo study, after 6 weeks of implantation, demonstrated that the two hyaluronan derived polymeric substitute materials, HYAFF120 and cell-loaded HYADD3 had a central NP-like region which had a close similarity to the normal biconvex structure and contained viable chondrocytes forming matrix like that of normal disc.

CONCLUSIONS: The strontium modified hydroxyapatite (Sr-HA) system presented appropriate osteogenic properties. Hyaluronic acid-based gels possess the unique NP extracellular matrix analogue behaviours. Both injectable systems demonstrated their easily injectability and highly bioactivity in both bone and NP repair/regeneration.

The impact of ancillary materials on your translational journey
L. Csontos
Presenting Author: Lynn Csontos, lynn.csontos@stemcell.com
1STEMCELL Technologies Ltd., Cambridge, United Kingdom

As the field of regenerative medicine surges forward with aggressive growth in clinical trials, the regulatory landscape for all aspects of the market continues to evolve. This continued growth has led to increased awareness around the need for specialized and complex materials utilized in their manufacture. Ancillary materials (AMs) are components or reagents used during the manufacture of tissue engineered products but are not intended to be part of the final product(s). Commonly, there are limitations in the availability of clinical-grade reagents used as AMs. Furthermore, AMs may affect the efficacy of the clinical product and subsequent safety of the therapy for the patient. As such, AMs must be carefully selected and appropriately qualified during the tissue engineered product development process. The global regulatory landscape surrounding AMs will be discussed complete with highlighting regional differences [1,2]. Case studies will be reviewed for specific AMs including cell culture media used in clinical applications along with how to identify a good versus poor supplier of Ancillary Materials.

Promises and future of bioprinting technic in cosmetic evaluation
M. Rielland
Presenting Author: Maïté Rielland, maite.rielland@rd.loreal.com
Cellular and Tissue Engineering Platform, Knowledge and Performance Department, Advanced Research, Research & Innovation, L’Oréal, Aulnay-sous-Bois, France

INTRODUCTION: Since last 80’, a long time before 2013 European Union ban on animal testing for cosmetic products, L’Oréal has placed itself as a pioneer for reconstructed human skin. It became one of the first cosmetic companies testing its raw materials/actives/formulations on in-house reconstructed human skin. Many different skin models are currently used in-house for efficacy and safety evaluation tests and knowledge of human skin physiology and pathology. However, one of the most challenge with in vitro models is to develop more relevant and predictive models according to cosmetic target (anti-aging, skin imbalance…). Bioprinting is a great alternative to create new models of skin with a complexity that cannot be achieved only by human hands. One of the biggest potential advantages of this technology is the ability to place cells or biological material where it needs to be placed, opening a few doors for tissue engineering. Taking advantages of our long expertize in skin tissue engineering, and thanks to new technologies (bioprinting, gene editing…), L’Oréal R&I aims to develop more predictive and pertinent skin models.

METHODS: Normal human fibroblasts or keratinocytes from skin plastic surgery wastes have been printed using inkjet or micro-extrusion printing methods or manually seeded. To reproduce the dermis part an internal Bioink has been designed.

RESULTS & DISCUSSION: Human normal keratinocytes, fibroblasts and melanocytes can be printed with good viability and can differentiate to form a correct epidermis or full thickness model. Histology and immunofluorescence on the main markers show that each cell types are functional. Taking advantages of those results, we have developed a patterned epidermal model were two type of keratinocytes are printed with different designs (figure 1). Interestingly they keep the design along the culture and form an epidermis with all differentiation layers and express correct epidermal main markers.

CONCLUSIONS: Skin models can be printed with correct viability, differentiation and expression of the main epidermal and dermal markers. We have developed a new epidermal patterned model with resolution that cannot be achieved only by human hands. This model could be used to study skin disease where the pathological and the healthy areas of the skin would be in the same sample leading to a more physiological in vitro model, improve the robustness and reduce the number of samples in evaluation tests.
Engineered microenvironments for stem cell engineering
M. Salmeron-Sanchez
Presenting Author: Manuel Salmeron-Sanchez, manuel.salmeron-sanchez@glasgow.ac.uk
Centre for the Cellular Microenvironment — University of Glasgow, Glasgow, UK

It is now well known that stem cells differentiation can be controlled by using the properties of the cell microenvironment. Much work has been done to understand the role of the elastic properties of the substrate and, more recently, viscoelasticity in stem cell behaviour. Stem cell response to these properties relies on integrin mechanotransduction and the activation of signalling pathways in response to the actual force performed by cells on synthetic extracellular matrices. Here we show that other less known properties of the substrate (e.g. pure viscosity without any elastic component) are relevant to control the dynamic properties – mobility- of integrins.1 We show control of the mobility of integrin ligands by using RGD functionalised lipid bilayers and, unconventionally, introduce functionalities on the bilayer to promote binding of other receptors, such as cadherins (HAVDI) and growth factor peptidomimetics (e.g. BMP-2). We show that the influence of targeting simultaneous integrin/cadherin receotors on substrates of controlled viscosity. In addition, we show the powerful effect of targeting simultaneously integrins and growth factor receptors. Based on this, we engineer 3D systems that promote bone regeneration by using ultra-low doses of BMP-2, and the potential to translate this receptor-targetting technology into clinical settings.

Technological challenges for the clinical translation and commercialization of TERM therapies
M.T. Raimondi
Presenting Author: Manuela T. Raimondi, manuela.raimondi@polimi.it
1Department of Chemistry, Materials and Chemical Engineering “G. Natta”, Politecnico di Milano, Milan, Italy

Mesenchymal stem cells (MSCs) raise a great interest for regenerative medicine for many clinical applications such as orthopedic, plastic and reconstructive surgery, within autoimmune or degenerative disease treatment and as immune-suppressive agents in organ transplantation. In stem cell therapy, cells are injected in the patient after an extensive in vitro manipulation aimed at obtaining a sufficient cell number able to guarantee the therapeutic effect. Currently, stem cell "manufacturing" implies the use of additives also from animal sources, hampering their clinical use mainly for safety reasons. I introduced a novel ground-breaking concept for an easy to use, repeatable, cost-effective, and safe substrate for stem cell expansion, called the “nichoid” substrate, capable of maintaining cell stemness through architectural cues, avoiding feeder cells and dangerous additives. The substrate is polymerized with a laser in a biocompatible resin using a frontier nano-fabrication technology called “two-photon laser polymerization” (2PP). The nichoid could drastically reduce down to few years the time to market of stem cell products that is currently 20 years. Another frontier technology developed by my group to accelerate the discovery of new drugs, including nanoparticle-based drugs and stem cell-based drugs, is the MOAB miniaturized optically-accessible perfusion bioreactor. The MOAB allows to culture 3D organoids of few millimeters in size, under continuous perfusion of the culture medium, infusion of the therapeutic agent to be tested and diagnostics of cell response both in real time and also post-cultivation. These two original platforms (the nichoid and the MOAB) are currently being integrated into a single device for the discovery and testing in vitro of new stem cell-based therapies. Another platform developed by my group to accelerate the clinical translation and commercialization of TERM therapies is the MICROATLAS miniaturized imaging window. This miniaturized implantable device explores the possibility to visualize and quantify in vivo the immune response to a biomaterial or a drug, including a stem cell-based biodrug, in the aim to reduce the ex vivo assessment required by current regulation. The use of a three-dimensional microstructured chip will allow repositioning the observation field of view of a two-photon microscope for intravitral inspections for repeated and quantitative measurements of cell recruitment, neo-angiogenesis and fibrotic reaction, at different time-points. At the same time, it will act as an efficient auto-fluorescent micro-beacon, providing volume reference to implement adaptive optics methods, which will improve intravitral image resolution sub-cute.

Glyco-functionalised neural interface coatings through heparan sulphate mimetics
M.J. Biggs
Presenting Author: Manus J. Biggs, manus.biggs@nuigalway.ie
Dept. of Biomedical Engineering & Science Foundation Ireland (SFI) Centre for Research in Medical Devices (CÚRAM), National University of Ireland Galway (NUI Galway), Galway, Ireland

Current strategies in developing functional brain-machine interfaces are focused on reducing electrochemical impedance while presenting neurotropic moieties to enhance device integration. The use of biochemical functionalization of conducting polymer surfaces is being increasingly utilized to promote or inhibit specific biological interaction and promote chronic neuroelectrode functionality. In this study the physical, electrical and biological properties of a conventional conducting polymer - PEDOT are investigated following functionalisation with a heparan sulphate mimic termed F6. Experimentally, PEDOT/F6 coatings were polymerized galvanostatically on platinum/iridium probe microelectrodes. The cytocompatibility of the functionalized PEDOT coatings was evaluated by culturing isolated rat ventral mesencephalic (VM) cells on the polymeric coatings and performing quantitative immunostaining of relevant neural biomarkers such as β tubulin for neural outgrowth and GFAP for astrocytes. The synthesis of pro-inflammatory cytokines, chemokine factors and reactive proteins were also assessed in vitro. F6 functionalisation was shown to enhance neuroelectrode biofunctionality, as assessed by the promotion of VM cell presence and neurite outgrowth for up to ten days in culture. A neurotrophic effect imparted by F6 was observed through binding to multiple neurotropic growth factors. Further, the modulation of cytokine and chemokine activity in VM populations indicated a protective effect of F6 which may translate to an enhanced availability of neurotropic growth factors. These results may be particularly important for neuroelectrode coating designs with biological dopants as they show an overall reduction in inflammation profile while promoting neural growth. The study further promotes the exploration of other glycan mimetics to potentiate matrix-therapeutics strategies at the neural-tissue interface.
Engineering complex bio architectures to biomimic nature: A step closer to the development of artificial organs
M. Thurner
Presenting Author: Marc Thurner, Marc.Thurner@regenhu.com
regenHU Ltd. Switzerland

regenHU cutting edge biofabrication process creates infinite possibilities in the manufacture of artificial tissues and organs. By engineering Macro & Nano architectures in a single process unit, we have opened the door to a whole new world of possibilities allowing us to mimic biological systems identical to those found in nature. regenHU — a three dimensional biotechnology company, exploiting the potential of 3D bioprinting & cell based therapies — is a creative innovator in the development of biomedical products for regenerative medicine & drug discovery. Based in Fribourg, Switzerland, regenHU is a pioneer and global leader in its field, converging digital manufacturing (3D printing), biomaterials and biotechnology to create transformational innovations in Healthcare.
Electrospinning as a method for biomaterial manufacturing: An industry perspective
M. Thio
Presenting Author: Marco Thio, marco.thio@electrospinning.co.uk
1The Electrospinning Company Ltd., Harwell Campus, Didcot, Oxfordshire, United Kingdom

Restoring damaged tissue through regenerative medicine strategies has gained significant momentum over the last decade, with broad portfolios of biomaterials available to the end user. However, the vast majority of commercially available regenerative medicine products are based on processed collagen, decellularized donor tissue and ceramic-associated processes. Reconstruction of hard tissue such as bone is well established using decellularised bone granules/grafts from either human (allograft) or animal (xenograft) origin or synthetic substitutes such as TCP/HA. In most cases, these bone substitutes contain the natural bone building blocks such as calcium phosphates. In contrast to hard tissue however, soft tissue regeneration relies heavily on decellularised tissues such as skin, intestine, amniotic membrane and pericardium which not always mimic the tissue extracellular matrix they are meant to regenerate, offering the surgeon a compromise rather than an indication-specific solution. Electrospinning is widely acknowledged amongst the academic community as a method to produce scaffolds for cell culture & in vivo experiments. Features such as superior strength, controllable fibre diameter and fibre alignment and variable degradability allow the generation of indication-specific biomaterials that could outperform currently available medical devices. In addition, numerous publications describe the possibility of incorporating active pharmaceutical ingredients (API) within or surrounding the fibres providing a platform for drug delivery with potential use in major sectors such as wound care, orthopaedics and cell therapies. In this brief review, we provide an overview of the status and position of electrospinning as a method for clinical-grade biomaterial manufacturing and share our insights on the challenges and opportunities observed as a centre of excellence in biomedical electrospinning.
Articular cartilage is composed of distinct layers, each characterized by a unique cell morphology, biosynthetic profile, biochemical composition and ultrastructural organization. These zone-specific properties give each layer its specific functional role, which then allows the whole multilayered organ to provide its well-known mechanical and lubrication properties. There have been many tissue engineering studies performed to recreate aspects of the zonal architecture of articular cartilage in the hope of obtaining a more realistic chondral or osteochondral graft. 3D bioprinting has been proposed as an optimal technology to biofabricate articular cartilage due to its inherent layer-by-layer additive nature. Although 3D bioprinting is in its infancy, with the development of more advanced biomaterials and printing technologies, it would offer the potential to recreate spatial distribution of growth factors, drugs and morphogens necessary for cartilage regeneration. It could also be used to reproduce gradients in stiffness, surface lubricity, oxygen impermeability of the calcified cartilage layer which may be critical in clinical usage. In this presentation, we discuss material, hardware and software developments from our lab towards bioprinting more realistic cartilage grafts. To fabricate osteochondral grafts, a commercial bone bioink together with a custom enzymatically crosslinkable cartilage bioink [1] are used and interlocking mechanisms, mechanical and biological performance studied. Using an ear shape as a model system, we further compare the properties of casted, reinforced hydrogels to that obtained with 3D bioprinting [2] in terms of cell viability, extracellular matrix deposition and shape retention during different stages of the manufacturing. To conclude, as the tissue engineering field strives towards increasing complexity of cartilage models, studies are needed to identify which of these features are essential for in vivo success and which naturally develop as the graft matures. The role of bioprinting in providing these key properties of cartilage is being actively explored and if successful, would allow for major advances in treatment of osteoarthritis, reconstructive surgery and screening for disease-modifying anti-rheumatic drugs (DMARDs) and disease modifying osteoarthritis drugs (DMOADs).

2D substrates as innovative tools with dual therapeutic/regenerative behaviors
M. Grazia Raucci
Presenting Author: Maria Grazia Raucci, mariagrazia.raucci@cnr.it
Institute of Polymers, Composites and Biomaterials, National Research Council, Naples, Italy

INTRODUCTION: 2D materials such as graphene oxide (GO) and exfoliated black phosphorus (2D bP) can be used as alternative tools for bone metastasis treatment. Recent studies have shown the effectiveness of 2D bP and GO as photodynamic therapy (PDT) agents for cancer treatment [1]. This activity has been ascribed to their capability of generating singlet oxygen and acting as photosensitizers that, in presence of reactive oxygen species (ROS) and infrared light irradiation, constitute an essential component of PDT therapy. The idea was to use GO and 2D bP in the first step as anti-cancer agents and then as osteoinductive compounds. Indeed, 2D_bP is readily biodegradable inside the human body and produces nontoxic intermediates, such as phosphate, upon exposure to water and oxygen thus resulting a safe material able to induce osteogenic differentiation of cells and new tissue formation. Furthermore, the good mechanical properties obtained in a reduced state, high hydrophilicity and good biocompatibility of GO sheets suggest that it could also be an ideal nanoscale reinforcing filler for biocomposites for bone regeneration. Hence, we propose the in vitro use of 2D substrates (GO and 2D bP) as a strategy to inhibit the progression of osteosarcoma after surgery. At the same time, we have investigated the osteogenic effect of these nanosheets on in vitro model of new forming bone tissue.

METHODS: The biological studies were performed to evaluate the effect of 2D substrates on cell proliferation and osteogenic differentiation of human healthy (hMSC and HOb) and cancer cells (SAOS-2) with and without infrared irradiation treatment (IR). The cell morphology was evaluated by scanning electron microscopy, confocal microscopy and hematoxylin-eosin staining. The biocompatibility and osteogenic differentiation were checked in vitro by Alamar blue assay and ALP activity, respectively. The reactive oxygen species (ROS) production was evaluated with and w/o IR treatment by in vitro model inflammation. The effect of 2D bP on inflammatory response through pro and anti-inflammatory cytokine investigations on a co-culture model was also investigated.

RESULTS & DISCUSSION: The biological investigations on healthy cells demonstrated that 2D substrates (GO and 2D bP) improved cell attachment and proliferation, with the best expression of early marker of osteogenic differentiation (ALP) at day14. Opposite effects were observed on cancer cells with a reduction of cell proliferation and inhibition of ALP activity. Furthermore, 2D bP is able to increase antinflammatory cytokines (i.e IL-10) on co-culture model and to inhibit pro-inflammatory mediator synthesis (i.e. IL-6) thus suggesting the opportunity to prevent cancer-related inflammation.

CONCLUSIONS: This study demonstrated that 2D substrates (GO and 2D bP) enhance the growth and osteogenic differentiation of human healthy cells (HOB and hMSC) and inhibits the proliferation of osteosarcoma cells (SAOS-2). The inhibition of cell proliferation (SAOS-2) of 2D bP reveals its antinflammatory activity on an in vitro co-culture model of cancer-related inflammation.

Using induced pluripotent stem cells to model neurodegenerative diseases
M. Lagarkova
Presenting Author: Maria Lagarkova: lagar@rcpcm.org
Laboratory of Cell Biology, Federal Research and Clinical Center of Physical-Chemical Medicine, Moscow, Russia

Neurodegenerative diseases such as Parkinson's disease (PD), Huntington's disease (HD), spinocerebellar ataxias (SCA), amyotrophic lateral sclerosis (ALS), Alzheimer's disease represent a large group of various disorders that are associated with the gradual degradation and death of certain types of neurons. In most cases, these disorders occur for unknown reasons and are constantly progressing. Understanding and treating neurodegenerative diseases have been constrained by the absence of in vitro models, especially because culturing primary cells affected by the diseases is very challenging. Limitations primarily lie in the access to patient's tissues. However, the development of stem cell studies and the discovery of induced pluripotent stem cells (iPSCs) provided an important source of cells to conduct in vitro studies. The ability to generate patient-specific iPSCs offers a new paradigm for modelling human disease and for individualizing drug testing. Modern genome editing technologies allow for the correction of mutations in iPSCs obtained from the patients with hereditary forms of neurodegenerative diseases, which is important both for obtaining isogenic systems for modeling and for tasks of future personalized therapy. We have successfully established and characterized iPSCs of patients with genetically characterized Parkinson’s disease, Huntington’s disease and spinocerebellar ataxias 1 and 17. We also established reliable protocols of differentiation iPSCs into the cell types affected in each particular disease (dopaminergic neurons, GABA-ergic neurons, Purkinje cells) and 3D brain organoids. Established iPSCs-based models recapitulated disease pathology in vitro, as evidenced by mutant huntingtin protein aggregation, nuclear indentation, enhanced neuronal death during cell aging and dysregulated store operated calcium channels in HD model, and defects in pathways associated with the functioning of mitochondria, phagosomes and lysosomes in PD model. Comparison of models of Huntington's disease and ataxias will provide an opportunity to understand the general mechanisms of the development of polyglutamine neurodegenerative diseases.
Design of advanced polymer and hybrid materials for biomedical applications
M. Vamvakaki
Presenting Author: Maria Vamvakaki, vamvakak@materials.uoc.gr
Institute of Electronic Structure and Laser, Foundation for Research and Technology-Hellas, 700 13 Heraklion, Crete, Greece and Department of Materials Science and Technology, University of Crete, 710 03 Heraklion, Crete, Greece

Polymer and hybrid materials have been extensively employed in biomedical applications (i.e. drug delivery, tissue engineering, medical implants). Natural, as well as synthetic polymers, alone or in combination with inorganic materials (ceramics, metals, etc.) have allowed to prepare constructs presenting cell biocompatibility, bioactivity, controllable biodegradability and appropriate mechanical properties. Our approach in this field aims in the sophisticated design and synthesis of both polymeric and hybrid, non-toxic, biomaterials which promote cell adhesion, growth and proliferation, while also presenting multi-functional properties, i.e. anti-inflammatory or antimicrobial action, material induced cell differentiation and others, for use in tissue engineering scaffold fabrication. The hybrid, organic-inorganic materials are developed using sol-gel chemistry followed by multi-photon lithography to fabricate complex 3D architectures. Additional functionalities, such as natural antimicrobial agents have been incorporated to obtain multi-functional cell scaffolds. On the other hand, appropriately modified natural biopolymers (polysaccharides, proteins, etc.) and synthetic polyesters prepared via multi-step chemical processes, are covalently linked to form biodegradable comb copolymers or polymer hydrogels. These materials are evaluated in cell cultures as potential candidates for use in bone and dental tissue engineering. The strong cell attachment and good cell proliferation on the material surface, combined with its anti-inflammatory action on macrophages, underpin their promising use in the field. Current work, focuses on further material development to afford spatiotemporally controlled release of important biological factors from these multi-functional scaffolds aiming at the design of programmable, “smart” biomaterial-cell-bioactive 3D constructs.
Local controlled drug delivery: Tenured translation
M. A. Tryfonidou
Presenting Author: Marianna A. Tryfonidou, M.A.Tryfonidou@uu.nl
Utrecht University, Faculty of Veterinary Medicine, Utrecht, The Netherlands

Chronic low back pain patients present an urgent societal problem, as its onset is in the economically productive age. In 40% of the patients, pain related to degeneration of the intervertebral disc (IVD); inflammation mediates the degenerative processes and contributes to pain. Current treatments are initially conservative, with as final option highly invasive surgery such disc arthroplasty or spinal arthrodesis. There are several minimally invasive treatment strategies being developed in order address back pain and at least delay the process of disc degeneration. This keynote will concentrate on the translation steps taken and the challenges phased for local controlled drug delivery focusing on anti-inflammatory drugs. In the course of several public-private partnerships we have obtained data on the safety and efficacy of intradiscal biomaterial-based delivery of a COX-2 inhibitor, celecoxib (CXB), in inhibiting inflammation and pain in disc degeneration. To this end, the canine model was been extensively employed in preclinical studies. Canines develop disc degeneration with similar macroscopic, microscopic, radiological and clinical signs as humans. As such, canines can be employed as experimental animals for development of treatments for both human and veterinary patients. We demonstrated that biomaterials loaded with CXB hold great promise as long acting treatment of disc-associated back pain for both human and veterinary patients. The injection procedure is safe, high loading dosages are effective in reducing tissue inflammation and in halting the degenerative process without systemic and local adverse effects.

From cell-laden bone tissue engineering to personalized bone organoids
M. Rubert¹

Presenting Author: Marina Rubert, marina.rubert@hest.ethz.ch
¹Institute for Biomechanics, ETH Zurich, Zurich, Switzerland

To advance on the development of therapeutics/implants for bone disease treatment, it is imperative to create bone organoids that closely mimic the structural and biological complexity of bone tissues. Models should also provide a better understanding of the molecular mechanism and the evaluation of the structural changes in bone that occur during the bone remodeling process. 3D bioprinting is an attractive approach to overcome the unstructured scaffolds geometries, or the lack of control on cell and matrix organization with limited usage of different cell types governed in the conventional tissue engineering methods. Moreover, given the high automation and reproducibility, the use of 3D bone bioprinting offers a promising tool not only to generate engineered bone tissues for damaged bone replacement but also to create reproducible test bed models for drug or implant development in vitro.

One of the main challenges in 3D bioprinting of engineered bone relies on material selection. Inks must provide high fidelity for the printed scaffold geometries while assuring high cell viability and formation of a mineralized extracellular matrix. Efforts have already been made on the development of bioinks for 3D bioprinting of bone. However, these studies rely only on the assessment of rheological parameters of the inks and assessment of the cell viability after the printing process [1]. Mechanical properties of 3D extracellular matrix (ECM) influence stem cell differentiation towards the osteogenic lineage. While stiffer alginate-gelatine bioinks provide higher structural scaffold stability, lower stiffness 3D cell-laden scaffold better support bone-like tissue formation, cell survival, proliferation, differentiation and formation of a mineralized ECM in vitro. To move towards generation of bone organoids, co-culture of osteoblast and osteoclast cells resembling the bone remodeling process is needed. Co-culture models that lead to a coordinated osteoblastic and osteoclastic activity mimicking the human bone remodeling have been established. These models allow for the first time in vitro monitoring of the bone remodeling process non-invasively using micro-computed tomography. Co-cultured cells were seeded manually on salt-leached silk fibroin scaffolds. Translation from manual to 3D bioprinted seeded cells will open new avenues towards better understanding of bone physiology and to advance drug/implant testing in a relevant human bone model. Here, our experience with 3D bone bioprinting and development of organoid bone models using human cells will be discussed. Future prospects towards personalized bone organoids will also be addressed.

Development and GMP-compliant manufacturing of EV therapeutics: From preclinical research to clinical application

M. Gimona 1,2
Presenting Author: Mario Gimona, mario.gimona@pmu.ac.at
1Spinal Cord Injury & Tissue Regeneration Center Salzburg (SCI-TReCS), Paracelsus Medical University, GMP Unit Strubergasse 21, 5020 Salzburg, AUSTRIA 2Celericon Therapeutics GmbH, Strubergasse 21, 5020 Salzburg, Austria

Extracellular vesicles (EVs) derived from multipotent stromal cells (MSC) have gained increasing popularity as promising cell-free therapeutic agents for the treatment of a variety of medical indications [1]. Despite the huge but largely unexploited potential of EV-based therapeutics in relation to the evident biological and regulatory complexity, it is imperative to continue developing and improving scalable and reproducible purification protocols based on robust risk-based approaches, and to elucidate a potential Mode-of-Action through qualified potency assays in disease-relevant in vitro and in vivo models. Good Manufacturing Practice (GMP) compliance and a well-developed understanding of the benefit of regulatory requirements must be applied to EV-based biological therapeutics development. Regulatory compliance is an integral part of a stable manufacturing process and should guide prospective manufacturers of EV therapeutics at the earliest possible stage for the benefit of the patients. To reach the intermediate goal of clinically testing MSC-derived EVs, we have thus designed and validated a set of manufacturing and quality control strategies [2] to develop safe and efficacious therapeutics that are compliant with current regulatory requirements for pharmaceutical manufacturing. I will also discuss the rationale for testing human umbilical cord-derived MSC-EVs in selected indications with a poorly or unmet clinical need such as non-healing bone defects, enthesisopathies, spinal cord injury and implantation-induced cochlear injury. Preclinical data on tendon and bone regeneration as well as on neuroprotection and immunomodulation will be presented. Our data point in the direction of a multimodal alteration of cell physiology via immunomodulation and mechanosensation / mechanotransduction processes to enhance and support tissue regeneration.

ACKNOWLEDGMENTS: The outstanding contributions from Andreas Traweger, Eva Rohde and Karin Pachler, and the financial support of the EXOTHERA IT-AT 1036 and ExtraNeu Wiss2025 Projects are gratefully acknowledged.

Tissue engineering is an attractive strategy for tendon-to-bone interface repair. The structure and extracellular matrix composition of the interface are complex and allow for a gradual mechanical stress transfer between tendons and bone. We fabricated biphasic silk fibroin scaffolds. The scaffolds had two different pore alignments: anisotropic (tendon) and isotropic (bone). Total porosity ranged from 50 to 80% and pores were <100-300 µm. Young’s modulus varied from 689 to 1322 kPa. In addition, adipose-derived mesenchymal stem cells were cultured on the scaffolds. Biphasic scaffolds supported cell attachment and influenced cytoskeleton organization depending on pore alignment. In addition, the gene expression of tendon, enthesis and cartilage markers significantly changed depending on pore alignment in each region of the scaffolds. Subsequently, we administered these scaffolds in a patellar tendon enthesis defect model in the rat. As controls, collagen scaffolds and empty defects were used. The animals (n=12 per group) were observed for 4 and 12 weeks by X-ray, μCT, histology, biomechanics and qRT-PCR. No failure in any of the scaffold groups occurred. The empty groups and the collagen control showed ossifications in the tendon region, whereas the biphasic scaffolds did not. Histology and qPCR indeed confirmed tendon regeneration in the tendon part of the biphasic scaffolds. Furthermore, biomechanic testing showed superior results of the biphasic scaffolds over the control groups. The mechanical parameters were close to those of native patellar tendon enthesis. In conclusion, the biphasic scaffolds fabricated in this study show promising features for tendon-to-bone tissue engineering.
Nanosensitive imaging of tissue constructs and cells

M. Leahy,1,2 Presenting Author: Martin Leahy, martin.leahy@nuigalway.ie

1Tissue Optics and Microcirculation Imaging Laboratory (TOMI), National University of Ireland Galway (NUIGalway), Galway, Ireland, Science Foundation Ireland (SFI) Centre for Research in Medical Devices (CÚRAM), National University of Ireland Galway (NUIGalway), Galway, Ireland

INTRODUCTION: There is a clear need for non-invasive and non-destructive methods to map tissue engineered structures and cells at the nanoscale. The accessible spatial frequencies provide information about small, submicron structure and highly sensitive to structural changes such as collagen organization.

METHODS: We have developed nano-sensitive Optical Coherence Tomography (nsOCT) and spectral encoding of spatial frequency (SESF) imaging for visualization of internal structure with nano-sensitivity to structural changes in superficial 2D [1-3] and depth-resolved imaging and for super-resolution imaging.

RESULTS & DISCUSSION: Different modalities of the SESF images of the collagen scaffolds are presented in Figure 1. The size of all images is 11 × 11 μm. Collagen samples after 3, 7 and 21 days of culture, respectively becomes more uniform, and the range of the dominant structure is reduced. The same conclusion can be made from analysis of the SESF images (D, E, F), formed as maps of mean spatial period, and from the sSESF images (G, H, I).

CONCLUSIONS: Collectively, these data clearly illustrate the benefit of nsOCT and SESF for elucidating tissue and cell structure. Even in the presence of noise, a difference in structure of 0.1 nm can be detected.

Figure 1: Images of collagen fibres: Imaging of the collagen scaffolds as a function of the day of culture. (A, B, C) SESF images as maps of the spatial period at the maximal signal distributions. (D, E, F) SESF images as maps of mean spatial period. (G, H, I) sSESF images as maps of the correlation coefficient distributions (for other sizes of probing structure see Videos S6-S8 [6]). All images: 11 × 11 μm.

Role of kinematic load on cell behavior
M. J. Stoddart
Presenting author: Martin Stoddart martin.stoddart@aofoundation.org
AO Research Institute, AO Foundation, Davos, Switzerland

INTRODUCTION: The emerging field of regenerative rehabilitation aims to enhance regenerative medicine approaches by harnessing and enhancing the body's endogenous healing response by way of rehabilitation protocols after treatment. It is widely accepted that the musculoskeletal system is strongly regulated by mechanical load, yet most new repair therapies are developed and studied using static culture. However, due to the critical role mechanics plays in vivo, a more physiological loading regime in vitro would be more appropriate, and this can be achieved by the use of bioreactors. Multiaxial load bioreactors can be utilized to this end, by mimicking the articulating joint, thus acting as an in vitro test bed for novel cartilage repair strategies. Bone marrow derived mesenchymal stem cells (BMSCs) are frequently used as a source material for cell-based cartilage repair strategies, they are also present during marrow stimulation treatments such as microfracture. Using a complex, multiaxial load bioreactor, we have demonstrated that superficial shear, superimposed over uniaxial load, can provide a chondrogenic signal in the absence of exogenous growth factors, namely TGF-β [1]. In agreement with other studies, compression alone did not induce chondrogenesis, however shear superimposed on compression lead to a more robust chondrogenic response. As the study did not include exogenous TGF-β, it demonstrates that mechanical stimulation alone is able to direct human MSCs towards a chondrogenic phenotype. In a previous study we had shown that the chondrogenic response is modulated by the frequency and amplitude of the multiaxial load applied, suggesting that this model can be used to pre-screen rehabilitation protocols in vitro. Within this system, the application of multiaxial load leads to an increase in the production, and activation, of endogenous TGF-β by the mechanically stimulated cells [2]. Deposition of both glycosaminoglycan and collagen II are increased in asymmetrically seeded scaffolds when compared to homogenously seeded scaffolds. This is providing further insights into novel material design for cartilage regeneration. The applied load enables the production of growth factor gradients, and this induced anisotropy is an interesting example of naturally changes generated in response to physical loads. In addition to the effect of load on direct differentiation, it is known that biomechanical stimulation can modulate the cell secretome [3]. Investigating these changes may lead to new potential clinical targets, that may be present during articulation, to be identified. This offers new avenues for potential clinical therapies. One such marker is nitric oxide. Normally absent during static culture, it is found after the application of complex load. Whether this has a positive or negative influence, is still under investigation.

ACKNOWLEDGEMENTS: This work was supported by the AO Foundation and the Swiss National Science Foundation (Grant no. 31003A_179438 / 1).

Mesenchymal stem/stromal cells as a therapy for osteoarthritis: Mechanistic insights
M. Murphy
Presenting author: Mary Murphy, mary.murphy@nuigalway.ie
Regenerative Medicine Institute & Science Foundation Ireland (SFI) Centre for Research in Medical Devices (CURAM), National University of Ireland Galway (NUI Galway), Galway, Ireland

Although mesenchymal stromal cells (MSCs) represent an important technology in regenerative medicine, translation to clinical practice has been slow. Recent successes with market approvals slowly emerging have highlighted the potential of the cells as a therapy for multiple diseases. However, mechanisms whereby therapeutic effects are achieved are still unclear. Initial concepts of cell differentiation to various mesenchymal tissues have been replaced by a paracrine model with implanted cells licensed by the in vivo environment and responding by secreting immunomodulatory or tissue reparative factors. Early apoptosis of infused MSCs has also been shown to be involved in the immunomodulatory process. We and others have shown that intraarticular injection of mouse MSCs into osteoarthritic joints modulates the diseased environment through attenuation of inflammatory processes. However, low engraftment is also a feature after local cell injection. A small percentage of cells survive and, when labelled appropriately, can be retrieved from sham and osteoarthritic mouse joints using whole joint digestion and cell sorting. Retrieved MSCs formed colonies, proliferated ex vivo and showed differentiation capacity. Conditioned medium collected from the cells at early passages was capable of shifting the polarisation of macrophages towards an immunomodulatory state. Induction of apoptosis in parental MSCs in vitro also increased their immunosuppressive potential, with effects on both T-cells and macrophages, suggesting that apoptosis may contribute to therapeutic effects of MSCs in osteoarthritis. Molecular analyses of MSCs retrieved from osteoarthritic and sham-injected joints, and apoptotic MSCs was performed to highlight therapeutic factors involved in MSC modulation of osteoarthritis.
Mass production of core/shell nanofibers: Industrial perspective
M. Buzgo¹,²
Presenting Author: Matej Buzgo matej@inocure.cz
¹InoCure s.r.o., Politických vězňů 13, 110 00 Prague, Czech republic ²Institute of Experimental Medicine, Academy of Sciences, v.v.i, Vídeňská 1083,142 20, Prague 4, Czech Republic

Coaxial nanofibers are among the most promising tissue engineering systems. However, the mass production of core/shell fiber was a challenge from industrial point of view. This contribution reviews the evolution of core/shell electrospinning methods for mass production and industrial application.

Needle based coaxial electrospinning: The possibility to mimick ECM structure and drug release properties enables stimulation of cells and accelerates tissue regeneration. Needle based core/shell spinning methods were used for encapsulation of wide range of active molecules in TERM field.

Needleless coaxial electrospinning: Classical needle based coaxial spinneret was modified to enable increase of production. The systems based on pyramid electrode [1], linear cleft electrode [2] and two-chamber electrode [3]. The systems had increased production capacity. The industrial application is hampered by complex formation of core/shell layers, low stability of process and decreased homogeneity.

Needleless emulsion electrospinning: In order to enable high-throughput development of core/shell fibers with high quality, we have focused on emulsion spinning systems. They could be used for formation of core/shell fibers from immiscible polymeric liquids (i.e. water-oil, oil-water emulsions) [4]. In the contribution we present results from industrial up-scaling of technology and testing of reproducibility, stability and applicability for use in TERM. Needleless emulsion technology is a viable system for production of industrial-grade core/shell fibers and might be used for drug delivery system development in TERM.

Co-cultured complex 3D miniaturized and vascularized models for metastatic processes and drug investigations
M. Moretti1,2,3

Presenting Author: Matteo Moretti, Matteo.moretti@eoc.ch
1Regenerative Medicine Technologies Lab, Ente Ospedaliero Cantonale, Lugano, Switzerland 2Cell and Tissue Engineering Laboratory, IRCCS Istituto Ortopedico Galeazzi, Milano, Italy 3Fondazione Cardiocentro Ticino, Lugano, Switzerland.

Metastases of a primary tumor develop in specific organs depending on the tumor itself, e.g. breast cancer metastasizes preferentially to bone but not to muscle, through a multi-step process culminating with cancer cells (bCCs) extravasation through the endothelium. To study such a complex phenomenon and to find drugs potentially limiting its occurrence, present models are not adequate. In particular, in vivo models are limited by species-specific differences in biological mechanisms and in vitro models presently fail to mimic the complex microarchitecture and multi-cellular organization of native tissues. In this context, we generated miniaturized tissue-specific vascularized models based on human primary cells [1,2] and exploited them for drug evaluations. Microfluidic models were based on HUVECs embedded in fibrin gel, which formed perfusable microvascular networks (MVNs) during culture in the chip. We developed both bone and muscle mimicking chips, that were then used to study bCCs extravasation. We also investigated the role of platelets and neutrophils in the metastatic process and the effects of platelet 2b 3 integrin inhibition through a clinically used drug (Eptifibatide). Moving to meso-scale contructs, we generated a bone-remodeling model, based on HUVECs embedded in a fibrin gel with human primary osteoblasts, osteoclasts and macrophages, containing hydroxyapatite nanoparticles to mimic the mineral part of the bone. A muscle-like model was created through human myoblasts and muscle fibroblasts with vascular cells in fibrin gel. The meso-scale models were used to investigate bCCs proliferation and migration in different tissue models and the effects of a known anti-proliferative drug (rapamycin) on both bCCs and vascular cells. Using the microfluidic chip, we were able to monitor bCCs extravasation through the microvascular network in both bone and muscle-like environments. Furthermore, the presence of neutrophils and platelets increased bCCs extravasation whilst the addition of 2b 3 inhibitor reduced extravasation, by increasing anti-tumor effects of neutrophils and strengthening HUVECs junctions through decreased VE cadherin nuclear translocation. Within our vascularized mesoscale models, MVNs were found to be more developed in bone than in muscle tissue, and even more in the presence of macrophages. Nanoparticle presence did not affect microvascular network formation, allowing to increase both osteoblastic and osteoclastic activity. Seeding of bCCs in the bone and muscle models decreased significantly their growth in the muscle as compared to the bone model. Finally, addition of rapamycin to the system reduced also bCCs proliferation and affected vascular network organization in a dose-dependent manner. In conclusion, the use of our vascularized 3D human in vitro models allowed to better mimick the complexity and heterogeneity of human physiological systems. In particular, the generation of perfusable vascularized networks and the use of multiple cell types co-cultures enabled to recapitulate organ-specific bCCs metastatic processes from extravasation to invasion and proliferation. Finally letting us use these complex miniaturized human models to evaluate possible biological system responses to known drugs for anti-tumor purposes in an unprecedented manner.

Synthetic basement membrane analogues induce the formation of 3D tissue-like structures in 2D cultures
M. Santin
Presenting author: Matteo Santin, m.santin@brighton.ac.uk
Centre for Regenerative Medicine and Devices, School of Pharmacy and Biomolecular Sciences, University of Brighton, Huxley Building Lewes Road, Brighton BN2 4GJ, UK

The basement membrane (BM) is a specialised form of extracellular matrix that provides the structural support and the phenotypic control of various types of cells including vascular cells, epithelial cells and mesenchymal stem cells (MSCs). These functions are fulfilled through its various proteins; among them Collagen Type IV and laminin. The present paper shows the ability of a novel class of biomimetic biomaterials substrates, PhenoDrive, to mimic the mesh structure of Collagen Type IV while presenting bioligands of the laminin in an orderly spaced manner. Co-cultures of various cell types with human umbelical vascular endothelial cells (HUVEC) at a typical ration of 40/60 were comparatively studied on Matrigel-coated plasticware and PhenoDrive-coated plasticware. Morphological studies of co-cultures of either MSCs or human beta cells or hepatocytes or renal cells and neuroglial cells with HUVEC on Phenodrive showed the formation of an endothelial sprouting more consolidated than that observed on Matrigel with the respective tissue cells being preferentially organised into 3D structures resembling a vascularised tissue originating from the endothelial sprouting crossing points. When the tested tissue cells, of primary origin or cell lines, were co-cultured with HUVEC on Phenodrive, they expressed higher levels of their phenotypic markers and acquired improved paracrine activities. Such tissue engineering constructs has potential for clinical applications as well as organotypic cultures for the testing of novel drugs and nanomedicines.

Development of dynamic polymeric hydrogels for tissue engineering
M.B. Baker
Presenting Author: Matthew Baker, m.baker@maastrichtuniversity.nl
1Department of Complex Tissue Regeneration, MERLN Institute for Technology-Inspired Regenerative Medicine, Maastricht University, Maastricht, The Netherlands

Tissue engineering and regenerative medicine require the development of artificial environments to provide a niche for new tissue. A quintessential source of inspiration, the native extracellular matrix (ECM). Made from a complex mixture of proteinaceous macromolecules, non-covalent and dynamic interactions allow for unique mechanical, responsive, and biochemical functions. Inspired by these dynamic interactions, our lab focuses on utilizing supramolecular interactions and dynamic covalent bonds to create hydrogels with inherent dynamics and reversibility. During this talk, I will tell the story of development behind dynamic hydrogels, going from an idea on paper to a material to a cell-culture platform. These hydrogels can be rationally controlled in terms of stiffness and bioactivity, yet these dynamic hydrogels impart several unique properties including self-healing, viscoelasticity, modular biofunctionalization, and stress-relaxation. Consequently, they can provide both a biomimetic environment and a tool for exploring fundamental biomaterial development. Due in part to their uniquely dynamic networks, these gels have found initial success in applications ranging from simple cell encapsulation to 3D bioprinting to spheroid encapsulation. In a majority of cases, the dynamics of the network can be tuned to control not only the suitability of the material for its application, but also the way in which cells respond to the material.

ACKNOWLEDGEMENTS: Financial support was received from the Netherlands Organization for Scientific Research, (731.016.202 “DynAM”), the Province of Limburg, Brightlands Materials Center, and RegMedXB.
Engineered fibre and gel composite materials as potential bioinks

3D printing is a well-established technology across numerous fields. It has attracted attention in biomedical engineering due to its ability to produce well-defined structures in three dimensions at high spatial resolution. While 3D bioprinting builds on these principles and offers the potential to create 3D functional tissues with complex and hierarchical structures through the controlled assembly of biocompatible materials in conjunction with living cells. Cells and biological components are encapsulated in a hydrogel matrix, which collectively is known as the bioink allowing extracellular matrices and cells to be deposited with high precision mimicking the actual cellular arrangement of the tissue it is replicating. Acellular inks are also being developed to print complex porous scaffolds which can be later seeded with cells [1]. However, in order to realise the potential of bioprinting there is an urgent requirement to develop bioinks for a range of potential applications. This lecture presents some initial printing trials for recently developed acellular inks which are capable of being printed in relatively cheap commercially available printers. The systems discussed include: pneumatic micro-extrusion utilising subsequent visible light curing (gelatin methacrylate, Methacrylated Hyaluronan), thermally extruded (PolyLactic acid, polycaprolactone) and their combinations with novel nanofibre reinforcement and extracellular molecules (Chondroitin Sulphate). The concept of self-assembling bioinks through novel thiol coupling will be introduced. Particular attention will be paid to print optimisation using viscometric techniques and crosslinking optimisation to ensure structural integrity. Initial biological assessment of the developed inks will also be discussed taking the meniscus as a potential application while providing an outlook for these materials as future bioinks.

HA is a key extracellular matrix component involved in tissue development and regeneration, cell motility and viscoelasticity. HA is commonly employed for fabricating drug delivery and regenerative medicine constructs. Using an unconventional conjugation method, here we present a series of derivatives providing HA with tunable pseudoplasticity, temperature-induced gelation and dual enzymatic/light-induced gelation. HA was grafted via DMTMM-mediated amidation with: 1. an array of substrates for validating the method; 2. short alkyl chains; 3. Thermo-responsive moieties; 4. tyramine. Products were characterized via rheology, 'H-NMR and UV-vis spectrophotometry. Reaction kinetics and coupling yields were determined under a spectrum of conditions. The thermo-responsive derivative was employed to deliver chemokines in vivo. The HA-tyramine derivative was optimized for additive manufacturing with a dual enzymatic and light gelation. The thermo-responsive derivative was employed for in situ tissue engineering. We found increased cell density at one week within a rabbit osteochondral defect upon the delivery of chemokines compared to chemokine-free gel. This approach is particularly attractive as it may facilitate endogenous cell recruitment, eliminating the need of tissue harvesting and cell expansion. The use of HA-tyramine for AM revealed that: the dual gelation allowed good extrusion properties; cells can attach and spread; to obtain gelation, a low concentration of polymer and low degree of substitutions can be used. Furthermore, this approach negates the use of UV light, eliminating safety concerns regarding UV-induced DNA damage and tumorigenesis. We have demonstrated how chemical modification can improve properties of HA including viscoelastic profile, drug delivery and 3D printing capability.
Designing biosynthetic corneal implants for clinical application

M. Griffith 1,2

Presenting Author: May Griffith, May.Griffith@umontreal.ca
1Department of Ophthalmology & Maisonneuve-Rosemont Hospital Research Centre, University of Montreal, Montreal, Canada

Corneal blindness affects 23 million individuals worldwide [1]. An estimated 12.7 million individuals await transplantation with only 1 in 70 being treated due to a severe dearth of donor human corneas [2]. Artificial corneas have been developed as prostheses but the non-reversible surgical implantation and side effects have necessitated their use only as last resorts [3]. A range of stem cell-based techniques including expansion and grafting of epithelium [4], stroma [5] and endothelium [6] have successfully tested in clinical and pre-clinical trials. In addition, self-assembled scaffold-free techniques have successfully produced tissue equivalents but requires significant time or a cleanroom operating to Good Manufacturing Practice guidelines for advanced therapy medicinal products (ATMPs). For clinical application, particularly in low to medium income countries where majority of corneal blind patients are located, mass produced, off-the-shelf implants are therefore desirable. As such, a cell-free, full synthetic low-cost implant that can be easily customized is advantageous. Our team has developed cell-free implants comprising recombinant human collagen (RHC) and tested them successfully in first-in-human clinical trials [7-8]. The use of RHC was planned at the outset to avoid possible batch-to-batch heterogeneity, pathogen transmission [9] and severe allergies that can occur [10] with xenogeneic animal collagen sources. For patients with inflammation and severe pathologies, a synthetic phosphorylcholine-mimicking lipid with inflammation suppressing properties was incorporated leading to stable regeneration of the cornea in patients at high risk of rejecting conventional donor corneal transplantation [8]. However, for scale-up, full-length RHC is expensive to produce. Hence, short collagen-like peptides (CLP) conjugated to mechanically tough polymers, and shorter self-assembling artificial collagens have been developed by our team and others. An example of a CLP-based collagen analog in the corneas of mini-pigs has shown that such analogs can be functional equivalent to RHC-based implants. We have since tested several CLPs for potential use as implants. The use of CLPs and the design of implants to ensure immune compatibility will be discussed.

ACKNOWLEDGEMENTS: Financial support was received from an Indo-Sweden DBT-Vinnova grant, a Canadian Institutes of Health Research grant (PJ 155924), and the Caroline Durand Foundation Chair in Cellular Therapy, University of Montreal and the Maisonneuve-Rosemont Hospital Research Centre.

Will chondroinductive materials revolutionize cartilage regeneration?
M. Detamore
Presenting Author: Michael Detamore, detamore@ou.edu
The University of Oklahoma, Carson Engineering Center, Norman, OK, USA

One of the core tenets of our philosophy for tissue regeneration include the use of “raw materials,” where biomaterials themselves serve as both building blocks and bioactive signals. In recent years, a few groups around the world have gravitated toward cartilage matrix as a potentially chondroinductive material for cartilage regeneration. The major challenge to date in cartilage injury has been creating a biomaterial-only strategy that is capable of regenerating true hyaline-like cartilage without the addition of growth factors or exogenous cells. In the past few years, we have focused our efforts on establishing chondroinductivity in vitro, and in developing new materials synthesis strategies to provide ease of application for orthopedic surgeons in the operating room. By leveraging nanotechnology, we have developed a paste-like material constructed from cartilage matrix with encouraging mechanical performance post-crosslinking, and which avoids contraction after extended time. Looking to the future, we are working on next-generation approaches to chondroinductive materials. We have encouraging preliminary data which suggest the possibility of a chondroinductive response to a novel peptide sequence in vitro, which may be enhanced by simultaneous inclusion of adhesion peptides. Initial in vivo data in regeneration of rabbit femoral condyle cartilage defects may suggest promising regenerative capabilities with hydrogels based on these peptides. If indeed chondroinductive materials exist, and if they can be delivered easily, are safe, and can be provided at reasonable cost and with a reasonable regulatory strategy, chondroinductive materials may hold the potential to revolutionize cartilage regeneration.
Mechanobiology revisited: From phenomena to design of the biomaterial-tissue interface
M. Gasik
Presenting Author: Michael Gasik, michael.gasik@aalto.fi
School of Chemical Engineering, Aalto University Foundation, Espoo, Finland; Seqvera Ltd., Helsinki, Finland

Tissue engineering applications often rely on biomaterials as scaffolds, substrates or implants assisting in regeneration. It is now widely acknowledged that there are no "inert" biomaterials and all the features like surface parameters, porosity, chemical and biochemical interactions play critical role in the tissue-biomaterial interface formation, quality, and development. Cells seeded in traditional in vitro cultures often seen losing their phenotype, function and therapeutic potential. The expansion to 3D and more complex cultures requires a better understanding of biomaterial-related microenvironment modulators (e.g. surface topography, substrate rigidity, mechanical stimulation) to control cell function in vitro. One of the topics of interest is to measure, guide and predict the effect of modulation of biomaterial surface and applied mechanical stimuli on realistic fluids exchange and mechano-transduction on cell and sub-cell levels. Here we discuss these phenomena on two major cases: auto-mechano-transduction caused by cell cultures themselves (without explicitly applied external mechanical and biochemical stimuli) and mechano-transduction for cells seeded on specific scaffolds. The possibilities of utilizing multiplexing signalling are presented for a translation to cartilage regeneration engineering and some other applications. The benefits and limitations of the mechanobiology applications for these cases is also discussed.
Hybrid electroconductive platforms for the generation of mature cardiac organoids
M. Monaghan
Presenting Author: Michael Monaghan, MONAGHMI@tcd.ie
Trinity College Dublin, the University of Dublin, Ireland

Conductive polymers have emerged as a class of smart biomaterials that can harness flexibility and facile manipulation with intrinsic conductivity that can enable electrostimulation. Amongst such materials, poly (3, 4-ethylenedioxythiophene) (PEDOT) exhibits appropriate stability, biocompatibility and conductivity and is usually combined with polystyrene sulfonate (PSS) as primary dopant, rendering it highly soluble in aqueous environments and other polar solvents. Modification with crosslinkers and secondary dopants can provide an appropriate degradation resistance and high conductivity without compromising the biocompatibility of the material. To this end, our group has achieved the fabrication and optimization of 3D scaffolds of PEDOT: PSS crosslinked with a novel PEGylated moiety that can possess suitable electroconductive, mechanical and biocompatibility properties in tissue engineering applications. This smart biomaterial has also been tailored to act as a reservoir in non-viral gene therapy applications. Using lyophilization approaches we achieve scaffolds with defined pore geometries and eccentricities, whereby rat neonatal cardiomyocytes and human IPS derived pre-cardiomyocytes have been seeded and matured using mild pulsatile electric field stimulation we achieve robust organized cardiac organoids.
Macromolecular crowding to tune microenvironmental ECM architecture: From ultraflat 3D to bioprinted structure
M. Raghunath1,2
Presenting Author: Michael Raghunath, ragh@zhaw.ch
1Center for Cell Biology and Tissue Engineering  2Competence Center Tissue Engineering for Drug Development (TEDD), Zurich University of Applied Sciences, Switzerland

The extracellular matrix (ECM) arose with the evolution of multicellular organisms and their needs to contain cells into tissue compartments and organize them by function. Thus, the ECM is the microenvironment of differentiated or progenitor cells, including the fabled stem cell niches. Of note, these microenvironments are built by the cells themselves, either by those residing locally in a given tissue, or by cells that once have been there to do the job. The importance of the cellular microenvironment in controlling cell behavior and fate has been gaining attention in the fields of tissue engineering, regenerative medicine, and mechanobiology. This interest is reflected by intensive efforts to design and sell artificial or semiartificial microenvironments with the aim to mimic native ECM. During these activities, it has become apparently forgotten that cells have the intrinsic capability to make their own specific ECM in which they reside prior to their extraction for cell culture. However, standard culture conditions are highly aqueous, thus impairing efficient ECM deposition. For example, the deposition of collagen is dependent on the swift proteolytic cleavage of N- and C- propeptides from procollagen the very moment it is secreted into the extracellular space. Only then collagen triplehelices can assemble to form nascent fibrils and thus an insoluble scaffold around cells. Aqueous conditions make this and other enzymatic steps inefficient and tardy. This can be overcome by introducing macromolecular crowding (MMC) into the culture medium of monolayer cultures or hydrogels [1]. A variety of enzymatic steps is substantially accelerated, not only procollagen conversion, but also crosslinking and remodeling. Even more powerful is mixed MMC, the combination of two or more crowders with different molecular weights [2]. Crowders we use in this context are carbohydrate-based polymers of glucose (dextran), or sucrose (Ficoll). The resulting excluded volume effects restores some physiology in the system by accelerating enzymatic key steps in ECM formation, and by driving the supramolecular assembly of ECM components such as fibronectin, collagen and fibrillin. Thus, MMC empowers cells to construct rich microenvironments comprising a multitude of structural components and associated ligands and stored growth factors.

Two years after we published the Scar in a Jar [3], a platform to identify anti-scarring agents, it was adopted by the pharma industry. Using MMC, we could empower human bone marrow-derived stem cells to build their own ultra-flat 3D ECM and thus unleashed a dormant brown fat differentiation potential. Interestingly, exposure of 3D skin models to MMC in the submerged phase boosts the formation of the dermo-epidermal junction as evident by the expression of collagen VII. Internationally adopted applications are the production of stem cell matrix, and tuning the microarchitecture of bioprinted collagen hydrogels. This bodes well for the application of MMC also in the framework of bioprinting to mature printed tissues

ACKNOWLEDGEMENTS: Financial support from Biotechnet (NTN Swiss Biotech) and the Zurich University of Applied Sciences (ZHAW) is gratefully acknowledged.

(Bio) fabrication technologies are evolving rapidly, focusing on one of the main current challenges in tissue engineering (TE); the creation of support materials at the multi-scale that could elicit both an optimal cell behavior and an adequate mechanical environment. Composite constructs composed of soft hydrogels reinforced with micro-fibre scaffolds obtained by a Melt-Electrospinning Writing (MEW) process has demonstrated great promise for developing tissue engineered constructs with compressive properties compatible to native tissues. Although, cell differentiation and abundant matrix formation was observed, these novel composite constructs are not able to address the interplay of compressive, shear, and tensile stresses that tissues in the human body are subjected to. Here, additional strategies for the design and fabrication of fibre-reinforcement are reviewed. Also, new insights into the real structural deformation and reinforcement mechanism of these novel reinforced hydrogels are presented.
Engineering protein- and polysaccharide-based bioinks for bioprinting of personalised implants
J.M. Oliveira¹,²,³

The combination of reverse engineering, 3D printing and novel mimetic bioinks can be the perfect solution to address many important challenges that we still face in the fields of musculoskeletal tissue engineering and personalized medicine. This lecture overviews our recent advances in the development of protein- and polysaccharide-based biomaterials and bioinks of natural origin. A fast setting enzymatic-crosslinked silk fibroin (SF) bioink has been developed allowing the production of patient-specific implants [1], including human meniscus implant and human intervertebral disc. The tyrosine groups (5 mol%) present in silk fibroin allowed obtaining a hydrogel formation through enzymatic crosslinking. Horseradish peroxidase (HRP) and hydrogen peroxide (H₂O₂) were used and an optimization of the Enzyme/oxidizer ratio was performed to obtain a good printability. These bioinks presented good reliability, and the produced scaffolds showed promising features in terms of biocompatibility and memory-shape properties. We also recently developed Gellan gum-based bioinks that can be ionically-crosslinked [2] for tissue engineering and 3D printing of implants that can respect the patient anatomy. In brief, a novel generation of natural-based bioinks were developed for biofabrication of patient-specific and memory-shape implants aimed at finding applications in personalized medicine.

ACKNOWLEDGEMENTS: The FCT distinction attributed to J. Miguel Oliveira under the Investigator FCT program (IF/01285/2015) is greatly acknowledged.

Controlling the immune system to promote tissue regeneration – From inflammatory cytokines to regulatory T cells
M.M. Martino

Presenting Author: Mikaël Martino, mikael.martino@monash.edu

1European Molecular Biology Laboratory (EMBL) Australia, Australian Regenerative Medicine Institute, Melbourne, Australia

Although it is now well recognized that the tissue healing process is tightly regulated by the immune system, we still have little understanding of the key cellular and molecular mechanisms involved. Therefore, great efforts are required to reveal how immunity governs tissue regeneration, in order to design better regenerative strategies [1]. The role of inflammation driven by inflammatory immune cells and cytokines has been explored to some extent. For instance, we found that macrophage-derived interleukin (IL)-1β negatively regulate bone regeneration via inhibiting the regenerative function of mesenchymal stem cells (MSCs) and osteoblasts [2]. Based on these findings we engineered a stem cell delivery system based on a fibrin matrix which integrate an inhibitor of IL-1β signaling. Using this approach in a mouse model, we could significantly improve MSC-driven bone regeneration. More recently, we found that IL-1β also inhibits tissue repair and regeneration driven by growth factors. For instance, the inflammatory cytokine inhibits the signaling of bone morphogenetic protein-2 and platelet-derived growth factor-BB during bone regeneration. In addition, wound healing in diabetic mouse is impaired by an imbalance between IL-1β and IL-1 receptor antagonist (IL-1Ra). To overcome the negative effect of IL-1β in various tissues, we have engineered an IL-1Ra variant that displays very high affinity for the endogenous extracellular matrix (ECM). Using the engineered IL-1Ra we could significantly improve bone regeneration and diabetic wound healing in mouse models. In addition to the innate immune system, we also focus on how the adaptive immune system – in particular T cells – controls tissue repair and regeneration. Using various adoptive transfer and T cell depletion models in the mouse, we found that regulatory T cells (Tregs) are critical for skin, bone and muscle healing. Very interestingly, Tregs seem to promote tissue repair and regeneration in a tissue-specific manner not only via immune regulation (anti-inflammatory cytokines) but also by directly promoting morphogenesis. Based on these findings, we engineered various systems aiming at promoting accumulation of Tregs at sites of tissue injury and we could demonstrate that those strategies greatly improve tissue regeneration in mouse models of skin, bone and muscle. For instance, we have engineered the signaling of a novel Treg-derived cytokine to improve its capacity to support Treg migration and immunoregulatory function. Delivering the engineered cytokine at sites of injury in wild-type mice is able promote accumulation of naturally occurring Tregs, which induce tissue regeneration. Overall, designing strategies that control both the innate and adaptive immune systems holds great promises for regenerative medicine applications – in particular, novel systems which harness the pro-regenerative function of T cells.

Small animal models in bone regeneration research
N. Weissenbacher¹,²
Presenting Author: Nadja Weissenbacher, nadja.weissenbacher@pmu.ac.at
¹Institute of Tendon and Bone Regeneration, Spinal Cord Injury and Tissue Regeneration Center, Paracelsus Medical University, Salzburg, Austria ²Austrian Cluster for Tissue Regeneration, Vienna, Austria

For understanding basic mechanisms of bone healing as well as for the development of novel treatment strategies, animal models of bone defects are needed. The choice, which model to use is crucial for any successful research attempt. To study biological properties of implants, particularly regarding osteoinductivity, subcutaneous implantation models are used, allowing large numbers of test items to be screened. More complex models are required to simulate healing in a clinically relevant setting. Simple osteotomies, segmental bone defects of increasing size up to critical size are under investigation. Bone defects can be created in a number of locations: to reflect intramembranous ossification, defects in the cranium may be chosen, whereas to investigate endochondral ossification, lesions in long bones are used. The healing process following a lesion in a small animal strongly depends on the defect model and the animal species and strain chosen. In many models of long bone defects, fracture fixation is required to allow the animal to use the injured limb. No fracture fixation is required for defects in the cranium, in some species in the radius, the flat pelvic bones and the ribs. For choosing the optimum site for a bone defect, several aspects need to be considered: the mechanical load the bone needs to bear, the predominant mechanism of ossification in the bone chosen (intramembranous like in the calvarium or endochondral like in extremities), or if cortical or cancellous bones are to be used. The duration of bone healing depends on the distance of the bone ends, on the degree of mobilization or distraction, on vascular supply, and potential infection. Various rodent strains with a wide array of genetic attributes or defects are available. For the investigation of fracture repair, the femur of rodents is the most commonly used model. Both internal and external fracture fixation devices are available for stabilization, thus allowing experimental animals to maintain function of their limbs. Within studies and amongst published results commercially existing implants obviate the need of experimental implant design and help reducing the associated inconsistency of data. Other than large animal models, which are more costly but resemble more the situation in human patients, small animal models allow larger experimental approaches and offer the use of a wide array of molecular screening tools.
Collagen scaffolds with sustained insulin release and controlled pore structure for tissue engineering
N. Kawazoe
Presenting Author: Naoki Kawazoe, Kawazoe.Naoki@nims.go.jp
Research Center for Functional Materials, National Institute for Materials Science, Tsukuba, Japan

Numerous studies have been conducted on the design and preparation of porous scaffolds for regeneration of various tissues such as skin, cartilage, and bone. In particular, controlled and local release of bioactive molecules like growth factors from porous scaffolds can provide an effective strategy to control the complex and dynamic regulation of cellular processes such as cell proliferation and differentiation in a three-dimensional microenvironment and, as a result, to regenerate functional tissues. In the present study, hybrid scaffolds of biodegradable poly(lactic co-glycolic acid) (PLGA) microbeads and collagen were prepared by embedding insulin-loaded PLGA microbeads in collagen sponges. The hybrid scaffolds were cultured with human dermal fibroblasts to investigate the effect of locally released insulin on cell functions. The hybrid scaffolds were prepared as the following procedure. First, human insulin molecules were loaded into PLGA microbeads with a water-in-oil-in-water (w-o-w) double emulsion solvent evaporation method [1]. In the emulsification process, two different homogenization speeds (1,000 and 8,000 rpm) were used to control the microbead diameters. Each group of the resulting microbeads were mixed with collagen solution and pre-prepared ice particulates with diameters of 150 - 250 μm as a porogen [2]. The mixtures were freeze-dried and after then crosslinked via carbodiimide chemistry. The laser particle analysis demonstrated the two types of microbeads had diameters of 19.4 ± 1.6 μm (large) and 4.4 ± 0.9 μm (small), which were prepared at emulsification speeds of 1000 and 8000 rpm, respectively. The loading efficiency of insulin was 87.0 ± 2.0% and 85.1 ± 2.8% for the large and small size microbeads. The SEM observation confirmed that evenly distributed large pores ranging from 150 to 250 μm were formed in the hybrid scaffolds. The result indicated that the large pores replicated the same morphology and diameter range as the ice particulates. The large pores were interconnected, which is beneficial for cell penetration and distribution. Microbeads were homogeneously distributed on the wall of the scaffolds. In vitro insulin release from the scaffolds was studied under shaking at 37°C. The scaffolds had a lower initial burst and a more prolonged insulin release than did the free microbeads. A low initial release of 3.3 ± 2.6% and 5.7 ± 2.9%, respectively, was obtained from the hybrid scaffolds incorporated with large and small microbeads. The hybrid scaffolds exhibited cumulative release of approximately 70% insulin for 4 weeks. The bioactivity of the locally released insulin was evaluated by in vitro culture of human neonatal dermal fibroblasts. The DNA assay indicated that insulin released from the hybrid scaffolds promoted cell proliferation more effectively than did the insulin supplemented in the culture medium as a control. In particular, the hybrid scaffold prepared with large microbeads had a more linear release profile of insulin and a higher promotion effect on cell proliferation than that with small microbeads. The hybrid scaffold should be useful for skin tissue engineering.

Hands-on tissue engineering course for students from various educational backgrounds – A Fulbright-funded experience in Yerevan, Armenia

N. Sarvazyan
Presenting Author: Narine Sarvazyan, phynas@gwu.edu
George Washington University, School of Medicine and Health Sciences, Department of Pharmacology and Physiology, USA

INTRODUCTION: The goal of this presentation is to share the author’s educational experience conducting an introductory, hands-on course in tissue engineering in Yerevan, Armenia. The course aimed to spark students’ interest in tissue engineering field giving them basic knowledge of field’s principles and terminology. The experience was highly rated by the students and was complementary to their future careers including medicine, biology, physics or engineering.

METHODS: Multiple social media channels were used to inform potential applicants. The main goal of these wide advertisement efforts was to recruit an interdisciplinary group of students from any STEM field as well as of different career stages: from high school students to recent PhDs. Applicants were asked to submit their CV and a short letter of interest. During a follow-up interview, student's level of interest, time commitment, and his/her English language skills were tested. Twelve selected applicants were then organized into four interdisciplinary teams with the goal of forming maximally diverse teams. Two-hour long in-class mandatory sessions were held twice a week. Laboratory was available for any additional hours needed to perform team assignments between the sessions. During the last weeks of the course teams were given a complete freedom to create the simplest version of engineered tissue of their choice.

RESULTS & DISCUSSIONS: The structure of the course included a concise overview of main tissue engineering topics followed by demos and students exercises – all designed to be performed using minimal specialized equipment and supplies. The developed course can be conducted as a one-month intensive summer course, one-semester 4-5 credit hour course, or a two semester 2-3 credit hour course. Each section included a didactic and a practical part. During the didactic part, the instructor went over key material and answered any questions students had about it. This was followed by a demonstration that covered the basic steps of that week experiment. During the practical, hands-on part, students conducted experiments of their own with the instructor serving only an advisory role. During the last three weeks of the course teams were given a task to put together a simple prototype of their tissue of choice. During 2017 course, students decided to create tissue engineered versions of heart, liver, cartilage and skin. Course ended with teams presenting their efforts to general public using oral and poster presentations.

CONCLUSIONS: The course was extremely well perceived by the students and interested public. To help spreading interest in tissue engineering throughout Armenia and the Caucasus, participants of the course were asked to pick their favorite exercise and to write a draft of the experimental protocol in their native language. After editing and corrections, a handbook of tissue engineering protocols was then created to help conduct similar courses in the language of the host country.

ACKNOWLEDGEMENTS: Financial support from the United States State Department is gratefully acknowledged (Fulbright US Scholar Award to N. Sarvazyan). Author also want to thank the scientific staff and administration of the Institute of Physiology after L.A. Orbeli, National Academy of Sciences of the Republic of Armenia for hosting the course.
Convey scaffold design from university to industry is such a challenging road in medical device communities. This road is limited by several factors, including the need to understand native tissue behavior and incorporate this behavior into scaffold design and the ability to manufacture scaffold to those design specifications. Scaffold needs to be characterized in relationship to the behaviour of the tissue that is intended to replace. The ability to bring clinical requirements earlier into the scaffold development process is a critical issue for study sections and investigators. For investigators developing scaffolds, the ability to get clinical insight for specific applications and to look towards developing scalable manufacturing methods is critical to easing the path to the clinic. Furthermore, it is necessary to evaluate scaffold characteristics with respect to specific applications, ASTM standards, and FDA guidance documents. For study sections and funding agencies, it is also important to prioritize funding of interdisciplinary research teams that bring clinical issues early into the scaffold-development process. Furthermore, it will be important for funding agencies and study sections to fund development issues in addition to basic research.
It takes two to tango: The promises of hybrid 3D bioprinting
N. I. Moldovan^1,2,3
Presenting Author: Nicanor Moldovan, nimoldov@iupui.edu

^13D-Bioprinting Core Laboratory, ‘Richard L. Roudebush’ VA Medical Center, and Departments of ^2Biomedical Engineering & ^3Ophthalmology, Indiana University-Purdue University Indianapolis, USA

Bioprinting is set to become one of the most disruptive next-generation biofabrication technologies. It aims to revolutionize tissue engineering and thus to improve the way we study disease mechanisms, discover new drugs or assess the effects of chemicals on living tissues, and eventually change how we treat diseases. So far, bioprinting mainly rode the wave of additive manufacturing revolution, imitating the technically similar 3D printing (i.e., layer-by-layer deposition of a material). However, this approach is dependent on the printability of the ‘scaffold’ biomaterial (bioink), which also has to accommodate and support the live cells. In spite of the constant progress in this area, a universal bioink capable to serve all the requirements of the bioprinted constructs, is still to be found. Therefore, an increasingly sophisticated array of technological add-ons is incorporated into the bioprinting process, some exploiting the resources of biomaterials, while others trying to minimize their involvement. A radically different variant of biofabrication uses only cells for creation of complex 3D tissue similars. These scaffold-free methods mostly rely on the properties of spheroidal cell aggregates. Correspondingly, scaffold-free bioprinting methods emerged, capable to assembly multiple spheroids into larger construct [1]. One of the most significant development is the microneedle-assisted spheroids skewering (‘Kenzan’ method), enabled by the commercialization of the robot Regenova [2]. Our University recently acquired one of the few such instruments outside Japan. However, scaffold-free bioprinting is not without its own limitations, and for this reason the field is looking back to the secondary incorporation of biomaterials within the bioprinting workflow. In my talk, I will illustrate opportunities [3], problems and current and contemplated solutions for the bioprinting of useful tissue models, arguing that an ultimately successful technology is likely to be ‘hybrid’ [4], thus emulating the modular-combinatorial nature of biological processes themselves.

ACKNOWLEDGEMENTS: The IUPUI Regenova bioprinter was funded by the NIH ‘Shared Instrument Grant’ S10 OD23595.

Nanosilicate clay promotes healing in a murine model of chronic skin wounding
N. D. Evans¹
Presenting Author: Nicholas Evans, n.d.evans@soton.ac.uk
¹Centre for Human Development, Stem Cells and Regeneration, University of Southampton Faculty of Medicine, Tremona Road, Southampton, SO16 6YD, United Kingdom

INTRODUCTION: Sorptive clays have been used since prehistory by humans as a material to treat skin abrasions and wounds. Despite this, there is a paucity of studies that systematically address the efficacy of defined clays in improving skin wound healing. In this study, we tested the hypothesis that a well-defined, synthetic smectite clay, Laponite, could increase the rate and degree of healing in chronic skin wounds in the non-obese diabetic mouse strain db/db.

METHODS: Full thickness skin wounds of 6 mm diameter were made in the back skin of db/db and wild type mice with a biopsy punch. 50 µL Laponite clay gels (3% w/v in H₂O) or controls of phosphate buffered saline (PBS) or alginate (1.1% w/v) were applied 24 h post-wounding and held in place with a semi-occlusive dressing. Wound size and re-epithelialisation was measured for up to 18 days post-wounding using photographic or morphometric analysis. Blood vessel infiltration, epithelial thickness, neutrophil count and cell density were measured using immunohistochemistry at d14 and d18.

RESULTS & DISCUSSION: Laponite treatment significantly promoted the rate of re-epithelialisation (100% vs 47 ± 43 µm), epithelial cell division, epithelial thickness (and fibroblast invasion compared to PBS or alginate-treated db/db mice (p < 0.01; n = 3). Moreover, in Laponite-treated mice, hair follicle anagen was stimulated in proximity to the wound concurrent with wound healing improvement, but was absent in PBS- or alginate treated wounds. Neutrophil infiltration was reduced in Laponite compared to alginate or PBS-treated controls. We suggest that Laponite may act to localise host proteins or growth factors at injury sites and promote skin wound healing processes.

CONCLUSIONS: We suggest that Laponite may act to localise host proteins or growth factors at injury sites and promote skin wound healing processes. Our data indicate a role for well-defined nanosilicate clays in wound healing and hair restoration.

ACKNOWLEDGEMENTS: Financial support was received from the University of Southampton Eustice Award, a Grundy Educational Scholarship to D Page, and from a small grant from NovoNordisk.
Human textile: The next generation vascular grafts
N. L’Heureux
Presenting Author: Nicolas L’Heureux: nicolas.lheureux@inserm.fr
Laboratory for the Bioengineering of Tissues (BioTis) U1026 INSERM/Université de Bordeaux, Bordeaux, France

Sheets of Cell-Assembled extracellular Matrix (CAM), produced by cultured cells in vitro, have been rolled to produce completely biological tissue-engineered vascular grafts (TEVGs). Despite a rapid and successful progression to clinical trials, this approach remains complex. Our novel strategy is to produce TEVG with yarns produced from CAM sheets using a textile-based approach, which is faster, more reliable, more versatile and more easily automated. CAM sheets can be cut in ribbons of various width, which can also be twisted to make threads. Yarns (ribbons or threads) can be processed in different ways: devitalized (freezing/dehydration/freezing/rehydration cycle), decellularized (8 mM CHAPS, 1 M NaCl, 25 mM EDTA, 0.12 M NaOH) and/or gamma-sterilized (25 kGy). We have evaluated the effect of these processing steps on the histological and mechanical properties of the yarn. Also, we have assessed the impact of these steps on the remodeling (histological and mechanical) of the yarn after subcutaneous implantation in a nude rat for up to 6 months. Results showed that the CAM-based yarn creates very little inflammatory reaction and is essentially only mildly remodeled by the host response. However, some processing steps do lead to increased reactivity and decreased performance in vivo. Because of its structure and versatility or use, the CAM can truly be called a “bio-material”. More importantly, because of its native-like structure, this material has the potential to be accepted by the host without significant immune responses and to support a long-term “physiological” remodeling process.
Immunoprofiling in tissue engineering and immune assisted tissue engineering via macrophage containing scaffolds

The replacement of complex organs with multiple functions such as larynx (swallowing, speech, prevention of aspiration) requires hybrid systems of mechanical and biological components. Following our initial positive results after clinical application of a completely mechanical, valve-based, titanium artificial larynx system [1]; we are currently developing tissue engineered connectors that will enable faster integration of our artificial larynx. However, the significant variation of the shape, size and mechanical properties, particularly after radiotherapy, of larynx between the patients requires the development of personalized solutions that are specifically designed for a patient which can diminish the level of reaction by the host due to a better mechanical and anatomical match between the implant and the surrounding tissue. Beyond the anatomical match, the patient’s immunological profile (where our efforts are focused on mimotope variation analysis based immunoprofiling) and the specific reactions to a given material (where we use transcriptomic approaches to detect patient specific reactions to materials such as titanium as a model) must also be considered for better clinical outcomes. The determination of patient specific components of the adverse immune reactions enables the development of personalized immunomodulatory solutions [2]. In this context, the control over macrophage phenotype in the microenvironment of implanted artificial tissues has strong therapeutic potential. In this talk, the surface modification of the implants and engineered tissues with autologous macrophage and/or immunomodulatory cytokine containing hydrogels for improving the physicochemical interface and biological crosstalk between the implanted structures and the host immune system will be covered. Our most recent efforts are focused on direct incorporation of phenotype controlled innate immune cells in hydrogels in the presence of connective tissue cells for more rapid maturation of vascularized connective tissues as support structures in artificial organ development. The potential advantages of such systems in the specific case of an artificial larynx will be elaborated. Also, with the potential testing of such structures in dedicated robotic simulation systems, where biomechanical environment of larynx/pharynx can be mimicked, will be discussed with the demonstration of a first version of such a robot (SWALL-E).

Many biomaterials have been proposed to produce scaffolds aiming the regeneration of many tissues. We have a particular interest in developing systems combining natural polymers and synthetic biodegradable polymers. By proposing those systems for those demanding applications, we aim at obtaining biomaterial systems with enhanced properties namely mechanical properties, processability, cell-friendly surfaces and tunable biodegradability. Our biomaterials may be processed by melting routes (solvent-free) into devices with wide applications such as biodegradable scaffolds, films or particles and adaptable to many biomedical applications. As an example of processing technologies, electrospinning has recently gained popularity as a simple and versatile technique to produce synthetic polymeric ultrafine fibers. This technique allows the production of non-woven meshes with fiber diameters in the nanometer range, which results in a high surface area-to-volume ratio and high porosity. Additionally, these nanofiber meshes can mimic the extracellular matrix of human tissues and, therefore, can be used as scaffolds for Tissue Engineering (TE) applications. Many sources of cells were considered for tissue engineering. Embryonic, iPS and adult stem cells are among the most promising to achieve the cell numbers required to have therapeutic relevance. We have been proposing adult stem cells from different sources for bone and cartilage tissue engineering applications. This talk will review our latest developments using natural-based biomaterials and nanofibre meshes in the context of bone and cartilage tissue engineering applications.
Development of 3D cellular microenvironments as potential remedy

Current clinical protocols for tissue regeneration incorporate the use of a supporting material along with transplantation of stem cells at the site¹. This approach aims to repair the damaged tissue by replenishing the lost tissue. However, clinical translation of stem cell-based interventions is prevented by poor functional integration and cell survival into the host tissue in accordance to the restraint of large constructs to rely on interstitial fluid diffusion and blood perfusion for nutrients and oxygen supply and waste removal². Extracellular matrix based hydrogels can be used to promote cell integration into the host by providing spatial and mechanical support for cell adhesion and survival. In a large graft, the core is under hypoxic conditions that lead to cell death. An engineered functional three-dimensional (3D) vascular network within the graft will support and induce tissue regeneration. Assembly of the tissue specific cells (i.e., bone, tumour, neuronal or adipose tissue), mesenchymal stem cells as a source of pericyte precursors³, and vascular cell populations into functional tube like structures infers that communication between cell types is required for tissue homeostasis. Based on the bidirectional communication between cells, it is hypothesized that a hydrogel scaffold composed of natural biopolymers such as collagen and hyaluronic acid, will support functional integration of endothelial cells, and tissue specific cell populations to re-establish vascular networks and promote the reconstruction of the local vasculature. This engineered network will inosculate with the host vasculature upon implantation and reduce the time required for a true functional graft vasculature to form and consequently will support and induce superior tissue regeneration⁴. Herein, our efforts and experience with co-culture systems to develop vascularized tissues used to in vitro model tissues for fundamental studies related to drug screening, disease modeling, as well as tissue repair and regeneration will be discussed.

Modeling myogenesis in vitro using directly reprogramed induced myogenic progenitor cells
O. Bar-Nur
Presenting Author: Ori Bar-Nur, ori.bar-nur@hest.ethz
Department of Health Sciences and Technology, ETH Zurich, 16 Schorenstrasse, 8603 Schwerzenbach, Switzerland

Transplantation of satellite cells offers an attractive approach to treat degenerative loss of muscle mass, however ex vivo expansion of these cells has proved challenging. We recently described a method that enable direct lineage reprogramming of mouse fibroblasts into expandable satellite cell-like “induced myogenic progenitor cells” (iMPCs) by transient MyoD overexpression combined with treatment of three small molecules. Undifferentiated iMPCs propagate extensively in vitro while expressing markers of skeletal muscle stem and progenitor cells, including Pax7 and Myf5, and can further differentiate into contractile myotubes that express mature skeletal muscle markers. Furthermore, iMPCs differentiate into dystrophin-expressing myofibers upon transplantation into a mouse model of Duchenne Muscular Dystrophy, and a subset of transplanted cells contribute to the satellite cell pool and maintain Pax7 expression in vivo. In this talk I will present our recent efforts to reprogram various defined somatic cells into expandable myogenic stem/progenitor cells, and the pivotal role small molecules play during this cellular transition. I will further discuss our efforts to generate novel in vitro stem cell-based models for Muscular Dystrophies using this unique myogenic cell culture system.
Two decades of research on amniotic cells: What have we learned?
O. Parolini\textsuperscript{1,2}

Presenting Author: Ornella Parolini, ornella.parolini@unicatt.it
\textsuperscript{1}Istituto di Anatomia Umana e Biologia Cellulare, Università Cattolica del Sacro Cuore Facoltà di Medicina e Chirurgia, Largo Francesco Vito, Rome, Italy \textsuperscript{2}Centro di Ricerca “E. Menni” Fondazione Poliambulanza Istituto Ospedaliero, Via Bissolati, Brescia, Italy

Perinatal cells can be isolated from different birth-related tissues, including different regions of placenta and amniotic fluid. In addition to hematopoietic stem cells, other tissue-specific cells with stem/progenitor characteristics have been identified. The First International Workshop on Placenta-Derived Stem Cells defined stem/progenitor cell populations from four major placenta regions: human amniotic epithelial cells, human amniotic mesenchymal stromal cells, human chorionic mesenchymal stromal cells, and human chorionic trophoblastic cells. Cells with MSC properties have also been isolated from other placental tissues, such as the chorionic villi, the maternal decidua basalis, from different compartments of the umbilical cord, such as the Wharton’s jelly. The notable interest that perinatal cells have received in the past decade is due to their low immunogenicity and high immunomodulatory potential, in addition to practical reasons such as their easy procurement. The uniqueness of perinatal MSC is their intrinsic immunomodulatory potential that doesn’t require pre-conditioning with inflammatory stimuli; this is likely due to their origin – a battlefield of the fetal-maternal immune crosstalk. In the field of regenerative medicine, we have learned that immunomodulation plays a relevant role to favor tissue homeostasis after injury. As a matter of fact, immunomodulation, rather than direct cell differentiation, has been shown to be a key mechanism contributing to the regenerative capability of perinatal cells, whereby they activate endogenous tissue stem cells that in turn contrast degenerative phenomena. Our group has pioneered the understanding of the immunomodulatory potential of mesenchymal stromal cells isolated from the amniotic membrane (hAMSC) of human term placenta. We have described the ability of hAMSC and their conditioned medium (CM-hAMSC) to reduce in vitro T cell proliferation induced by alloantigens, via T-cell receptor or mitogens. hAMSC and CM-hAMSC significantly reduce the expression of markers associated to Th1 and Th17 populations, and significantly induce the regulatory T-cell compartment. Amniotic cells are able to block the differentiation of monocytes into both dendritic cells (DC) and inflammatory M1-macrophages, and skew monocyte differentiation toward anti-inflammatory M2 macrophages. The therapeutic effects of amniotic cells and their conditioned medium (which contain secreted bioactive factors) have been reported in other preclinical models of diseases based on inflammatory processes and with altered immune reactions, such as lung and liver fibrosis, sepsis, inflammatory bowel disease, cardiac ischemia, autoimmune encephalomyelitis, rheumatoid arthritis and Huntington’s disease. In these diseases, the modulation of inflammation seems to be a key element underlying the restoration of tissue integrity promoted by amniotic cells and their bioactive factors. The multifaceted, immunomodulatory properties of cells isolated from the amniotic membrane of human term placenta, and conditioned medium derived from their culture, render them precious cells for a variety of therapeutic applications, especially inflammatory-based diseases. The future will unveil the underlying mechanisms of action of amniotic cells and, in addition, novel therapeutic applications.
The lymph node niche as an ex vivo tool for T cell priming
Ø. Halaas 1,2

1Department of Clinical and Molecular Medicine, NTNU The Norwegian University of Science and Technology, Trondheim, Norway.

Vaccinations have prevented more human suffering than any other medical technology, and will continue to serve in therapy of cancers of infectious diseases for the foreseeable future. Today’s immunization regimes is based on injecting immunogens into the body, whereupon dendritic cells (DCs) having acquired the immunogens, as well as the immunogen itself, is translocated to the lymph node where T cells (and B cells) from blood and lymph scavenge the DCs in search of cognate epitopes. For T cells, this occur in a densely cell populated area in the lymph node paracortex, the T cell zone, resulting in priming and activation of a diverse set of T cell subtypes subsequently responding to any cell presenting the epitope in the context of MHC (HLA). The possibility of creating immune responses in vitro opens a whole new range of opportunities in immunotherapy, but this is technically and physiologically difficult. We approach this challenge by creating 3D networks of reticular fibroblasts in microbioreactors, and administer DCs and T cells by perfusion, by this aiming to recreate the dynamic microenvironment of the lymph node. We show shear stress-affected antigen specific adhesion of T cells to DCs. We show migration of DCs and T cells on the scaffold. We further describe the cell phenotypes affected by the microenvironment and the mechanical cues, create 3D models of T cell priming process and perform functional testing of the T cells.
3D goes clinical - Modified islet transplantation as blueprint for future 3D cell transplantaion

We are at a tipping point where nature is revealing us top secrets of life. We can reveal them when we look at life how it really is - in 3D. 3D cell culture systems reflecting real life processes thus provide not only sound scientific data, but they also enable regenerative medicine with stem cells. Almost every life begins with cell clusters. 3D cell clusters are therefore an ideal scientific model that offers additional therapeutic options. But for full functionality, clusters need to be size-controlled in a physiological, “cosy” environment. Unfortunately, current technology is limited to either quality or scalability, and therefore many desired applications are not possible. Because of this unmet medical need, we therefore developed the Sphericalplate 5D, enabling the full translation from lab to clinics with freely scalable, size-controlled spheroids in clinical grade quality. A human multicenter trial for the treatment of Diabetes is beginning in 2020.
Getting on nerves: In vitro models of engineered tissue
P.A. Wieringa

Presenting Author: Paul Wieringa, p.wieringa@maastrichtuniversity.nl
1Complex Tissue Regeneration Department, MERLN Institute of Technology-Inspired Regenerative Medicine, Maastricht University, The Netherlands

The peripheral nervous system (PNS) is critical in regulating tissue function and homeostasis, with supporting evidence that innervation also plays a role in tissue repair [1]. Furthermore, innervation can impact the effectiveness of organ transplantation and influence pathological conditions [2]. However, innervation is rarely considered in regenerative medicine strategies. While in vivo studies have been critical to show that the nervous system plays a role in these processes, there are also conflicting findings [3]. This can be attributed to the various targets which are simultaneously contacted by the nervous system, triggering activity in other regions of the body which may also subsequently influence the tissue of interest through the release of hormones or paracrine signals. This complex interplay between these tissues and the PNS can result in confusion and controversy and is a contributing factor to the marginalization of innervation in tissue engineering approaches. In vitro models can effectively eliminate uncontrolled confounding factors and provide a defined context to explore nerve/tissue interactions. However, classical 2D cell cultures often cannot support the formation of representative tissues, limiting the types of interactions and functional readouts that can be assessed. Discussed here is our development of a 3D in vitro platform that supports directed innervation of 3D cultures and can be reconfigured to support various target tissues. The approaches described intend to provide a universal tool that clarifies the role of the PNS within regenerative medicine and that provides strategies to achieve meaningful innervation.

Engineered and devitalized cartilage extracellular matrix as a bone substitute material
P. Bourgine

Presenting Author: Paul E. Bourgine, paul.bourgine@med.lu.se

1Laboratory for Cell, Tissue and Organ Engineering, Department of Clinical Sciences, Wallenberg Centre for Molecular Medicine, Stem Cell Centre, Lund University, Sweden

According to reference books, our bones can form by intramembranous and/or endochondral ossification. The endochondral route involves the formation of cartilage tissue as primordial template, initiating the development of most bones and their healing upon fractures. Several groups in the past years have demonstrated that by engineering cartilage in vitro using different mesenchymal stromal cells (MSC), the tissue has the capacity to robustly remodel into bone and bone marrow. In this context, hypertrophic chondrocytes contribute to the bone formation, following the natural process of endochondral ossification. The successful recapitulation of the endochondral approach has opened new avenues in tissue engineering, with the increasing exploitation of cartilage tissue for bone repair. This lecture will offer evidences that not only living cartilage can be used to form bone, but also devitalized templates. Using both human primary and immortalized MSC, cartilage matrix can be engineered and subsequently devitalized by apoptosis induction. Despite being cell-free, the templates show strong bone inducing stimuli by retaining essential osteoinductive signals. This has been demonstrated at ectopic (subcutaneous) and orthotopic (calvarial defect) sites, using static scaffold-free culture or scaled-up systems based on perfusion and 3D porous scaffolds. Bone formation was also assessed in the presence of co-delivered stromal vascular fraction cells freshly isolated from adipose tissue, which could be intra-operatively available for enhanced matrix remodeling. Although inspired from development, the described approach hijacks the natural endochondral process; forming bone via a cartilage intermediate, but without involving hypertrophic chondrocytes. The findings will be further discussed in light of the challenges to understand and control the activated biological processes, in order to achieve a superior level of robustness, standardization and possibly customization depending on the specific demands of defined clinical settings.

Intuitive design of melt electrowritten products for tissue engineering and regenerative medicine
P.D. Dalton¹

Presenting Author: Paul Dalton, paul.dalton@fmz.uni-wuerzburg.de
¹Functional Materials in Medicine and Dentistry, University Clinic Würzburg, Germany

Melt processing has been used for decades to manufacture medical materials including sutures, hernia meshes and bone screws [1]. Also using melt processing, scaffolds made by 3D printing are used to fill maxillofacial defects [2]. In this lecture, the intuitive design of soft-tissue implants made from medical-grade poly(ε-caprolactone) (PCL) using a technology termed melt electrowriting (MEW) is described [3]. Briefly, MEW operates with air-pressure control, driving molten PCL to a flat-tipped nozzle with 5-6kV applied. Calibration curves for both air pressure and speed were performed so that the direct-writing of multi-phasic and multimodal scaffolds performed [4]. MEW scaffolds consist of small filament diameter structures in the low-micron resolutions. The diameter of the fibers within the scaffold can also be controlled. There are many possibilities for scaffold design, Since the diameter of the fiber can be discretely changed, multiphasic and multimodal scaffolds can be designed and 3D printed. All scaffolds are melt processed with methods friendly to the medical device regulatory process. In summary, MEW, is a robust, reproducible and solvent-free approach to manufacture 3D printed materials for soft tissue applications. It bridges the divide between solution electrospinning and fused deposition and is an inexpensive approach that permits clinically translational research to be performed in university settings.

ACKNOWLEDGEMENTS: Financial support was received from the German Research Foundation (DFG) – Project number 322483321.

3D bioprinting with adult stem cells. Roadmap for translation to clinic

P. Gatenholm
Presenting Author: Paul Gatenholm, paul.gatenholm@chalmers.se
3D Bioprinting Center, Chalmers University of Technology, Göteborg, Sweden

3D Bioprinting has a potential to revolutionize regenerative medicine due to unique ability to place multiple cell types in predetermined position and build bottom up the microenvironment to control cellular fate processes. We have investigated the effect of bioink and bioprinting conditions of stem cell-laden biopolymer hydrogels on cell viability. We found multiple factors such as; cell mixing process, printer head design and most important; rheological properties of the biopolymeric bioinks affecting cell viability. We discover that nanofibrillar hydrogels were most beneficial due to orientation of fibrils in the nozzle and decreased shear forces. Bone marrow derived mesenchymal stem cells and adipose derived stem cells, ASC were successful 3D bioprinted with high viability and implanted directly subcutaneously in nude mice. We were not able to observe neither proliferation nor differentiation during 30 days in vivo. In contrast, we have seen significant effect of stem cells onto human chondrocytes when 3D bioprinted co-culture. Stem cells contributed to proliferation of chondrocytes and increased production of cartilage. This trophic effect of stem cells is enhanced in 3D bioprinted constructs due to controlled microenvironment. Our studies together with plastic surgeons have been expanded to up to 1 year implantation and use of different protocols for cell isolation. We have also showed that 3D bioprinted mechanically disintegrated adipose tissue constructs survived engraftment in vivo and displayed macroscopic and microscopic evidence of neovascularization. The roadmap for translation of this technology to clinic which includes cell isolation protocols and use of regulatory compliant bioinks will be presented.
Mechanisms and characteristics of extracorporeal shock wave therapy
P. Slezak
Presenting Author: Paul Slezak, paul.slezak@trauma.lbg.ac.at
1Ludwig Boltzmann Institute for Experimental and Clinical Traumatology, Austrian Cluster for Tissue Regeneration, Vienna, Austria

Extracorporeal shockwave treatments have been shown to accelerate tissue regeneration in diverse clinical situations, ranging from soft to nerve and bone tissue applications. The underlying mechanisms of these mechanically induced beneficial effects on cells and whole tissue volumes are not yet fully understood. Furthermore, the physical properties of the acoustic shockwaves that are produced by various generating techniques (electro hydraulic, electro-magnetic) are not yet properly characterized. In a co-operation with the major manufacturers of therapeutic shock wave applicators we have performed analysis of various clinically used devices, evaluated their physical properties as well as their biologic effects on cells. Optical phase contrast imaging was used to visualize shockwaves in various in vitro test setups and a computational model has been established to calculate the propagation of shockwaves and to simulate treatment options. This allows planning, prediction and optimization of complete therapeutic sessions. Beyond the computational work, different types of shockwaves have been tested with various cell types, ranging from animal derived cells to fungal biofilms. Increased cell proliferation as well as augmented resistance of fungal biofilms to antimycotics was shown in vitro, outline the protective and regenerative potential of acoustic shock waves in a broad range of indications once more.

Figure 1: Simulation of the peak pressures and summative energy applied to a tissue volume during an extracorporeal shockwave therapy session with an electo-hydraulic device; 300 pulses, 4cm penetration depth. Comparison between a random (A) and spiral (B) application pattern.

ACKNOWLEDGEMENTS: The author would like to thank Cyrill Slezak, Anna Weihs, Christiane Fuchs, Roland Rose, David Hercher, Kyle Hutchings, and Dr. Olga Kopp and her team for the support of this project.
Despite considerable progress in biomaterials science and regenerative medicine over the past 20 years, numerous challenges and unmet clinical needs remain. This is undoubtedly the case in musculoskeletal repair, where issues related to the ageing population and an increased prevalence in co-morbidities have placed considerable burdens on healthcare systems while reducing the quality of life for millions of people worldwide. Two persistent challenges today are poor or inconsistent musculoskeletal tissue regeneration, and deep bone infection (that is frequently device-associated). Moreover, these two major issues are increasingly combined in elderly patients where – especially when combined with the increase in antimicrobial resistance - they present clinicians with one of the greatest challenges in medicine today. Research at Sheffield, frequently undertaken with academic and industrial partners, has identified a number of highly promising innovations that could both enhance musculoskeletal tissue regeneration and combat infection (directly, and/or indirectly via a reduction in risk). Some of these technologies are relatively simple and therefore close to translation to a useful product, whereas others are more complex but could underpin a new approach to clinical regenerative medicine. At the most straightforward level, there are inorganic modifications to existing technologies, for example the substitution of metal oxides in bioactive glasses to enhance bone tissue response and/or introduce antimicrobial activity. Substitution of calcium with strontium in Hench’s classical 45S5 bioactive glass composition was previously shown to stimulate bone tissue regeneration [1], and we now have a good understanding of both the materials science and biological mechanisms responsible [2]. Modification of bioactive glass composition to enhance biocompatibility and antimicrobial activity has been extended to different systems [3,4], and in parallel work an important discovery was that nanoscale calcium phosphates could also be modified - in this case with silver - to introduce potent antimicrobial activity against opportunistic pathogens. More technically complex approaches include the multilayer nanoscale encapsulation of therapeutic molecules including antibiotics. To summarise, recent research has provided a range of highly promising technologies that have the potential to enhance musculoskeletal tissue regeneration while reducing the risk of deep bone infection. These represent the first generation of truly multi-biofunctional biomaterials, and this paper will conclude with an analysis of the translational pathways that are best suited to bringing these innovations to clinical trial and adoption.

ACKNOWLEDGEMENTS: Financial support was received from EC, UK EPSRC, and industrial partners including Ceramisys Ltd. Bringing TERM to the market by employing hybrid approaches
P.F. Costa¹
Presenting Author: Pedro Costa, pedro.costa@biofabics.com
¹BIOFABICS – 3D Biotissue Analogues, Porto, Portugal

The translation of science to the market continues to be a rather long and painstaking process. Nonetheless, scientists are becoming increasingly aware of it and more often considering this path for their newly developed technologies as well as their own careers. This trend may be explained by the current influence of entrepreneurial culture in society, by a greater visibility of successful scientists turned entrepreneurs as well as by an increased awareness among the scientific community towards the meager availability of exciting career progression opportunities in academia. The field of tissue engineering and regenerative medicine (TERM) is no exception to this. Despite being a relatively young field, large numbers of highly skilled researchers have been trained in this area of knowledge in the past few decades, at the cost of substantial investment and fueled by the promise of being able to replace and regenerate tissues, organs and body parts in the near future. Nearly thirty years past, and despite many breakthrough advances, the promise did not yet fully turn into reality. However, this does not mean that opportunities were not created. In particular, many new research labs and companies were created since then, taking advantage of the newly trained human resources and the new know-how generated. Such labs and companies may have remained focused solely on TERM or also spun out to many other fields of application. The past decades have shown us that it may be wiser for TERM-based companies to keep an open eye towards other fields where TERM-based technologies can be more easily applied and where markets are more mature or simply easier to reach. This talk will mainly discuss how TERM-based companies can and should embrace the ability to collaborate and combine various technologies and know-how across disciplines, fields, sectors and borders in order to reach broader markets and therefore more successfully translating TERM to the market, whatever and wherever it may be.

ACKNOWLEDGEMENTS: This project has received funding from the European Union’s Horizon 2020 research and innovation programme under the Marie Sklodowska-Curie grant agreement No 798014.
Biofabrication techniques for scaffolds manufacturing: The complex development for osteochondral regeneration

P.G. Morouço¹

Presenting Author: Pedro Morouço, pedro.morouco@ipleiria.pt

¹Biofabrication Research Group, Centre for Rapid and Sustainable Product Development, Polytechnic Institute of Leiria, Portugal

Biofabrication allows the formation of 3D scaffolds through a precise spatial control. This is of foremost importance when aiming to mimic heterogeneous and anisotropic organization, as wished for the osteochondral tissue. However, osteochondral defects keep being a supreme challenge for TE of the musculoskeletal system. It is quite challenging to design and fabricate TE constructs resembling the different compositions and mechanical properties of bone and cartilage, as well as their interface. Due to its nanostructure of complex stratified architecture and contrasting biomechanical properties, attempts to mimic integration at the cartilage-bone interface have failed. Furthermore, most of the current research focus on repairing focal cartilage damage, failing in to address the entire osteoarthritic joint. The recent advancements in 3D biofabrication, has permitted the design and fabrication of patient-specific scaffolds that possess structural and functional features comparable to the native tissue. It allows for design and fabrication using tissue images captured with commonly used medical imaging techniques such as computer tomography (CT) and magnetic resonance imaging (MRI) that are readily available in hospitals, something that conventional fabrication techniques lack. The mechanical properties of developed scaffolds should be directly related to their microarchitectural topology. As such, the permeability of a porous scaffold could be manipulated to mimic the native tissue and to facilitate cell and nutrient movement and allow for a better host-tissue integration as in osteointegration [1]. Accordingly, scaffolds have a determinant role for providing the proper 3D environment, so that cells can proliferate and differentiate in adequate lineages. To do so, both the used biomaterials/bioinks, as the fabrication techniques should be evaluated. Regarding the biomaterials, there are advantages and drawbacks on using synthetic or natural polymers for the scaffolds production [2]. On the fabrication techniques, there is a trend to accept additive manufacturing techniques as advantageous procedures, as it enables a customized product design, with development and fabrication for patient-specific applications. With this presentation we will discuss the effects on boosting an effective synergy between mechanical engineering (including robotics automatization) and biomedical sciences. That will benefit TE from the revolutionary steps in manufacturing at industry 4.0. Revolutionizing the available procedures for tissue repair and regeneration: bringing the robotics expertise to the biofabrication domain, it will be possible to promote an outstanding precision with the ability to develop stimuli-responsive implant, employing a combination of responsive materials and novel construct geometries to amplify the consequence of the material response. We will provide up-to-date examples on significant steps on tailored implants for osteochondral tissue regeneration, as well as demonstrate what we should expect in the near future.

Landscape of regenerative medicine and tissue engineering in Russia
P. Timashev
Presenting Author: Peter Timashev, timashev.peter@gmail.com
1Institute for Regenerative Medicine, Sechenov University, Moscow, Russia 2Institute of Photonic Technologies, Research Center “Crystallography and Photonics”, RAS, Troitsk, Moscow, Russia 3Department of Polymers and Composites, N.N. Semenov Institute of Chemical Physics, RAS, Moscow, Russia

INTRODUCTION: In the last decade, Russia has become an active player in the field of tissue engineering and regenerative medicine. While this field is of high priority and intensively developing all around the world, it is essential to provide a framework of the place and role of Russia. In this study, we analyzed the local research pattern, revealed trends in publication and clinical trial activity and discussed the background determining them.

METHODS: Publication and clinical trial activity was studied using Scopus and clinicaltrials.gov databases respectively.

RESULTS & DISCUSSION: We revealed that the amount of publications in the field of regenerative medicine and tissue engineering written by Russian scientists annually increased from 1998 to 2018, and during this period it rose almost in 24 times. However, last two years the publication activity was approximately on the same level. The same trend was noticed for clinical trials. The government has started to create the required environment to enhance research in this field and its clinical translation by passing the new law regulating the production of biomedical cell products and acting from 2017. Due to historical background, tissue engineering and regenerative medicine in Russia differ from other countries and are strongly connected with physics (especially laser technologies), material science, and mathematics. The highest amount of research centers working in this field are concentrated in the central part of Russia, particularly in Moscow and Saint Petersburg. However, there are strong research teams located in Tomsk and Novosibirsk, which are placed in Siberia.

CONCLUSIONS: Today, Russia with its distinctiveness mainly formed in the USSR during the Iron Curtain period is opened to collaborations with scientists from all over the world giving a birth to the new generation of scientists who work in the field of tissue engineering and regenerative medicine and creating non-trivial approaches [1-4].

ACKNOWLEDGEMENTS: Financial support was received from the Russian Science Foundation (18-15-00401; analysis of publication and clinical trial activity) and Russian academic excellence project 5-100 (background analysis).

Biofabrication of different tissue models based on methacrylated gelatine
P.J. Kluger¹

Presenting Author: Petra J. Kluger, petra.kluger@reutlingen-university.de
¹Reutlingen University, Reutlingen, Germany

INTRODUCTION: Additive manufacturing techniques are increasingly used in tissue engineering to generate complex tissue structures. Therefore, bioinks are needed to build up 3D-geometries, maintain cell viability and function to enable the maturation of the tissue after printing.

METHODS: Human primary cells (ASCs, Adipocytes and endothelial cells) were isolated from different biopsies as described in [1-3]. Hydrogels based on methacrylated gelatin (Fraunhofer IGB) were used and modified with hyaluronic acid, hydroxyapatite particles [4,5,1]. Cells were encapsulated into these inks to achieve tissue specific bioinks that can be printed by microextrusion in different geometries. Moreover, constructs containing two different bioinks were manufactured. These hydrogels were cultured under static or dynamic conditions in a perfusion reactor [6], for up to 28 days. Tissue constructs were characterized e.g. by using different staining techniques or rheological measurements.

RESULTS & DISCUSSION: The encapsulation of different primary cells in methacrylated gelatin was successfully established. Numerous geometries for various tissue models were fabricated including viable and functional cell, proved e.g. by different immuno fluorescent stainings. The use of our tailor made tissue specific bioinks lead to an improved differentiation of e.g. ASCs to the osteogenic lineage measured by rheological methods [7]. Even more physiological performance of the cells were found in coculture approaches especially in the formation and stability of new formed vessel like structures [2]. Other models were directly printed in our perfusion bioreactors and cultured there for up to 28 days. Thereafter, a maturation of the tissue models could be visualized by detecting proteins like ALP or Osteopontin.

CONCLUSIONS: Different tissue models were successfully manufactured based on methacrylated gelatin. More physiological behavior can be achieved by adding tissue specific cues like tailored bioinks/components, coculture of cells and adapted culture conditions.

ACKNOWLEDGEMENTS: We thank the Dr. Kirsten Borchers (Fraunhofer IGB), the European Commission, the Carl Zeiss Stiftung and the Ministry of Science, Research and the Arts in Baden-Württemberg.

When you realise that you are actually trying to imagine what it is like to be an orthopaedic bone screw inside living bone, is the diagnosis midlife crisis or perhaps an epiphany? As a young engineer I escaped industry into biomedical engineering to take on the ultimate challenge of repairing people rather than machines. At that time the orthopaedic implant industry left it to surgeons to decide what healing bone needed. We implant makers gave them whatever metal implant they asked us to make. Much of what passed for implant design in that era was empirical and mechanical. With the empirical approach we developed an innovative hip fracture implant, the Gamma locking nail, that eventually becomes a world-wide standard of care. However, no matter how we modify the metal lag-screw part of this implant it still migrates through poor-quality bone at a similar rate to earlier devices. In my moment of epiphany, inside the lag-screw hole in cancellous bone, I visualize the many trabecular struts in contact with the implant and realise how little of the surface is actually solid in poor quality bone. It becomes obvious in an instant that a biomaterial is needed that can effectively bridge between implant and the many weak bony struts. The biomaterial could be a calcium phosphate cement or, to dream, even an adhesive. When I test the idea of a bone glue with surgeons, they list many clinical situations where they too dream of a bone glue. This changes the direction of my life: from development engineer to scientist, from employee to entrepreneur and from metal implant making to biomaterials formulation. After many travails we eventually develop a bone glue [1], and in an evidence-based world where no such biomaterial exists, there are many hurdles in qualifying this as both safe and effective for human use. In this talk to the TERMIS learned society I will share some of hard lessons learned in translating from bone screws to bone glues.

ACKNOWLEDGEMENTS: Financial support for the OsStic bone adhesive project was received in part from EIT Health HeadStart grant (2018 HS PoC 2018-HS-0046).

Immunomodulatory programming and antimicrobial activity by new biomaterials
P. Lavalle¹

All implantable biomedical systems face several risks once in contact with the host tissue: excessive immune response to the implant and development of bacterial biofilms. A multifunctional surface coating that can address all these two issues concomitantly would significantly improve clinical outcomes. We hypothesized that polyarginine (PAR), a synthetic highly cationic polypeptide, can act on macrophages to control innate immune response because arginine is an important component of macrophage metabolism. Moreover, PAR is susceptible to act as an antimicrobial agent due to its positive charges. We developed a new polyelectrolyte multilayer film based on PAR and hyaluronic acid (HA). The layer-by-layer PAR/HA films have a strong inhibitory effect on the production of inflammatory cytokines released by human primary macrophages subpopulations [1]. This could reduce potential chronic inflammatory reaction following implantation. Next, we show that PAR/HA films were very effective to inhibit Gram-positive and Gram-negative pathogenic bacteria associated with infections of medical devices [2] [3]. We demonstrate that exclusively films constructed with poly(arginine) composed of 30 residues (PAR30) acquire a strong antimicrobial activity. Moreover, changing HA by another synthetic or natural polyanion did not provide any more antimicrobial activity. HA is a key component of the system and the mechanism behind this property has been elucidated. The cytocompatibility of the PAR/HA films was assessed with several cell types playing a major role in tissue regeneration. This all-in-one system that limits strong inflammation and prevent pathogens infections on implants constitutes a powerful material easy to scale up.

School of Engineering, Newcastle University, Newcastle upon Tyne, United Kingdom

The use of antimicrobial biomaterials is attractive in medicine and dentistry field, where the elimination of bacteria and device-associated biofilms is necessary for an effective treatment. For instance, the conventional periodontitis treatment is helpfully complemented by the additional administration of antibiotics, which can be applied by local or systemic administration. Compared to systemic drug delivery, in periodontology local administration is considered to be more effective, since the pathogen-specific drug can be positioned in the periodontal pocket with suitable concentrations for an adequately long time period. Moreover, the risk of undesired side effects caused by high systemic doses or resistance development can be drastically reduced. Thus, it is beneficial to use local delivery systems that control the release of their agents and guarantee lasting drug concentrations in the pocket. Therefore, innovative localised and controlled delivery system will be discussed in the treatment of dental and periodontal infections for: (1) reducing the released antimicrobials amount, preventing both drug-related systemic side effects and bacteria resistance, and (2) preserving the physico-chemical properties of the medical device without incorporating the antibiotic into the material bulk. Specifically, we propose the Layer-by-Layer (LbL) technique for coating biodegradable membrane by to obtain discrete nanoscale layers to (1) incorporate and control the release of the antibiotic drug with minimal interaction with the biomaterial substrate, or (2) propose a strong antibacterial material, Manuka honey, as negative-charged polyelectrolyte for the manufacturing of the nanocoating.
Maxillo-facial bone regeneration with stem cells and biomaterials in a comparative clinical trial

P. Layrolle

Presenting Author: Pierre Layrolle, pierre.layrolle@inserm.fr

1INSERM UMR 1238, PHY-OS, Bone sarcomas and remodeling of calcified tissues, Faculty of Medicine, University of Nantes, Nantes, France

INTRODUCTION: After loss of teeth, alveolar bone significantly resorbs over years and implant supported rehabilitation is often not possible. Autologous bone grafting, despite some disadvantages, is still considered the gold standard for reconstruction of maxillofacial bone defects. During the previous European project REBORNE, a novel bone augmentation protocol has been introduced (EudraCT, 2012-003139-50). It consists of mandible bone augmentation with autologous culture expanded mesenchymal stem cells and biphasic calcium phosphate granules prior to dental implants. The aim of this study is to compare bone regeneration by using cell therapy and biomaterials with autologous bone grafting in 150 edentulous patients.

METHODS: This clinical trial has received ethical and medicinal agency approvals. 30 ml of bone marrow stem cells (BMSC) were aspirated from the posterior iliac crest and plastic adherent mesenchymal stem cells were expanded in culture medium containing human platelet lysate for 2 weeks. During surgery, 100 million of BMSC were seeded on 5 cm³ of biphasic calcium phosphate (BCP) granules and inserted on the alveolar bone. After 4-6 months, bone regeneration was assessed by clinical examinations, cone beam computed tomography (CBCT) and histology of core biopsies.

RESULTS & DISCUSSION: Eleven patients have been successfully treated without adverse events. The combination of autologous cells and biomaterials induced significant new bone formation. After 4-6 months, the mean increase in bone width and volume was 4.05 mm and 887.2 mm³, respectively (n=14, p < 0.001). Histological analysis revealed that BCP granules were well integrated with deposition of newly formed lamellar bone tissue on the surface of the BCP particles in the entire core biopsies. The regenerated bone volume was adequate for dental implant installation. The patients were satisfied with the esthetic and functional outcomes.

CONCLUSIONS: These results warrant further clinical investigation in the MAXIBONE project challenging the current gold standard in bone augmentation such as autologous bone transplantation.

ACKNOWLEDGEMENTS: This clinical study has received financial support from the European Commission through the FP7 and H2020 projects REBORNE (241879) and MAXIBONE (779322).

20 years ago, we designed injectable bioactive suspensions in water of calcium phosphate ceramics for bone and periapical regenerations. Because of leakage of these suspensions, we focused on injectable hydrogels before to set in situ by chemical crosslinking to form 3D scaffolds. We set up a platform to develop a series of innovative hydrogels for bone, cartilages and periodontal tissue regeneration. We based our strategy on polysaccharides macromolecules because they are renewable materials, that originate from biological sources and generally are biocompatible, non-toxic and biodegradable. We developed a family of silated macromolecules able to react forming biocompatible hydrogels. The silated polymers are self-setting hydrogels able to covalently crosslink under pH variation, without addition of toxic crosslinking agent. All these macromolecules could be combined in multicomponent hydrogels, representing a strategy for improving mechanical properties of biomaterials or to tailor particular properties to meet specific needs. For mineral scaffolding, we realized composites of calcium phosphates particles or cements with hydrogel, increasing the ductility and creating macroporous scaffold to propose foam bone cements well adapted to bone biomaterials and Bone tissue engineering. Perspectives are 3D printing and bio printing techniques. We will use our hydrogels platform to prepare tunable (bio)inks in skeletal medicine.
Deciphering fate choices in mesenchymal stems cells
V. P. Shastri\textsuperscript{1,2}

Presenting Author: V. Prasad Shastri, prasad.shastri@gmail.com or prasad.shastri@makro.uni-freiburg.de

Mesenchymal stem cells (MSCs) have been long studied for their role in skeletal development. In adult physiology, MSCs are unique in that they exhibit pluripotency and differentiate into cells that can evolve into various skeletal tissue. As a result, they have been extensively employed as a viable alternative to terminally differentiated cells in engineering of cartilage and bone tissue ex vivo and in vivo. In spite of decades of effort in this direction, our understanding of what drives MSC fate choices is rather narrow in that it places heavy emphasis on a role for morphogens and cytokines (TGF-beta super family, FGF-2). In recent years it has become evident that MSCs also play an important role in wound healing, immunomodulation (immune suppression) and in tumor progression. While this points to a more ubiquitous role for MSCs in regenerative processes and tissue repair, what factors affect MSC fate choices remains to be fully unraveled. We hypothesize that activation of differentiation programs in MSCs have an autocrine and paracrine component involving interplay between MSC-MSC (cell-cell contact) and MSC-(environment), and in this signaling paradigm the biophysical aspects of their microenvironment play a dominant role. We have tested this premise in several aspects of MSC behavior (proliferation, migration, differentiation, chondrogenesis) and have gathered compelling evidence for biophysics and mechanobiology in MSC fate decisions. This talk will present some of our latest findings in this area.
Micro-3D printing of osteocyte organoid models
R. Mueller
Presenting Author: Ralph Müller, E-mail: ram@ethz.ch
Institute for Biomechanics, ETH Zurich, Zurich, Switzerland

INTRODUCTION: Osteocytes are deeply embedded in the bone matrix in lacunae and connected by dendritic cell processes through sub-micron canalicular channels. The morphology of osteocytes and their surrounding lacuno-canalaricular network (LCN) are hypothesized to regulate cellular mechanosensing [1]. Furthermore, it has been shown that morphological parameters like osteocyte shape, volume and number of dendrites are altered with aging and in diseases such as osteoarthritis and osteoporosis [2]. The role of these changes however remains elusive. Yet, it has been demonstrated in 2D that rounded osteocytes are more mechanosensitive than osteocytes spread on flat surfaces [3]. In 3D however, it has so far not been possible to manipulate the morphology of osteocytes and the LCN on the micrometer level to assess their effects on mechanosensing. We therefore aim to control LCN and cell morphology, particularly dendrite number, using a micro-3D printed osteocyte organoid model to mimic dendrite loss reported during aging / age-related disease.

METHODS: LCN-mimetic structures were micro-3D printed by two-photon-polymerization with a Nanoscribe GT 3D microprinter using inorganic-organic-hybrid polymer OrmoComp® (micro resist technology GmbH) and coated with Collagen I. Following 35 days of differentiation in tissue culture flasks, IDG-SW3 osteocytes (Kerafast Inc.) were dissociated using Trypsin-EDTA and Collagenase type II and reseeded on printed structures. 24 hours after reseeding, cells were fixed, stained with Phalloidin-TRITC, and mounted with Fluoroshield™ containing DAPI. Images were acquired by scanning confocal microscopy (Zeiss LSM880) and cells (n=92) forming dendrites in the artificial canaliculi were analyzed using FIJI. Dendrite length (n=333) was determined as the distance from the end of the dendrite to an ellipse approximating the cell body. Dendrite branches were disregarded in the analysis.

RESULTS & DISCUSSION: IDG-SW3 osteocytes in two micro-3D printed structures allowing for 10 or 6 dendrites per cell to be formed were investigated. The difference in the LCN-mimetic structures induced a major difference in the number of dendrites per osteocytes. Average length of dendrites and their length distribution were not affected, indicating undisturbed dendrogenesis.

CONCLUSIONS: We were able to mimic dendrite loss in 3D, one of the hallmarks of aging in bone. In the future, we will expand this concept to manipulate osteocyte cell volume and aspect ratio and assess their effect under mechanical loading. We believe that a micro-3D printed organoid is versatile tools to further our understanding of osteocyte mechanobiology.

Immunomodulation in intervertebral disc degeneration
R. M. Gonçalves
Presenting Author: Raquel M. Gonçalves, raquelg@ineb.up.pt
i3S-Instituto de Investigação e Inovação em Saúde; INEB-Institute of Biomedical Engineering, Porto, Portugal

Aging and degeneration of intervertebral disc impact on tissue function leading to low back pain, the first disorder in years lived with disability and a major burden in healthcare systems. Frequently, the inflammatory microenvironment has been strongly associated with disc degeneration. Besides native nucleus pulposus cells, immune cells namely macrophages, are known to be recruited to degenerated disc. However, it is still not clear the mechanisms behind the crosstalk of these cells and their contribution to the disease pathomechanism. To improve tissue regeneration, immunomodulatory strategies are gaining attention worldwide, either using biomaterials or cell therapies. In this work, anti-inflammatory nanoparticles based on chitosan and poly-gamma-glutamic acid with an anti-inflammatory drug, previously developed by our group, were able to reduce inflammatory markers in disc degeneration while promote remodelling of cartilaginous extracellular matrix (ECM), in a single intradiscal injection. We also demonstrated that mesenchymal stem/stromal cells (MSCs) reduce the pro-inflammatory gene expression of nucleus pulposus, but not anulus fibrosus, cells, under a pro-inflammatory microenvironment, which might explain the success of MSCs-based therapies in the context of low back pain. In the end, this presentation expects to highlight new ex vivo models of disc degeneration and associated inflammatory response and to disclose how immunomodulatory strategies can impact on degeneration of intervertebral disc.
Major scientific developments in several bio-related fields during the last three decades compelled new thinking and practices regarding implant biomaterials. Novel and seminal advances in the biological/physiological/medical fields have redefined the criteria and specifications for the design, synthesis, and formulation of biomaterials used for various implantable devices. Such approaches require close attention to advances at the tissue, organ, molecular, cellular and gene biology/physiology levels, keeping track of clinical needs and developments at the frontiers of medicine, as well as creative translation and application of the latest developments in the aforementioned biomedical fields to biomaterial designs and formulations pertinent to applications in tissue engineering and regenerative medicine. Currently design and development of novel biomaterials has reached a “steady state” plateau. Pertinent developments have been either incremental or “refinements” of existing biomaterials (e.g., those approved by federal regulatory agencies). How can the biomaterials field meet present challenges and benefit from future scientific advances? Undoubtedly, novel ways of thinking and practice are needed to assure a bright future for biomaterials in the age of tissue engineering and regenerative medicine. Pertinent approaches include (but are not limited to) the following: (1) redefinition of biomaterials-related criteria and specifications to address needs of specific biomedical applications; (2) training the next generations of biomaterial scientists/engineers to include basic biological/physiological sciences; (3) interdisciplinary teams of collaborating scientists, clinicians and engineers whose complementary expertise has the potential to provide solutions to current scientific problems/limitations, explore and advance new scientific frontiers, and thus develop the implant biomaterials of the future.
Where civil engineering and biology meet: articular cartilage
P.R. van Weeren

Presenting Author: René van Weeren, r.vanweeren@uu.nl

1Department of Equine Sciences and Department of Clinical Care of Companion Animals), Faculty of Veterinary Medicine, Utrecht University, The Netherlands

The main function of the non-contractile tissues of the musculoskeletal system (i.e. bone, cartilage and tendons/ligaments) is mechanical. These tissues give structural support to the body and they accommodate, transmit and to a certain extent dampen the (often considerable) forces generated by terrestrial locomotion. If those external challenges exceed the strength of the tissues, failure will occur. This may be caused by single major insult, but is more often an insidious process that is the consequence of wear and tear and gradual degradation. All of these tissues have a collagenous template as basis which is modified according to the demands made to the specific tissue. Calcium hydroxyapatite is deposited on the underlying collagen network of bone to provide rigidity, in ligaments and tendon collagen fibrils are arranged in parallel form complying with the tensile stress they are subjected to and may have more or less additional components such as elastin to increase elasticity in case of energy storing tendons, such as the Achilles tendon in humans or the superficial digital flexor tendon in horses. In cartilage it is the intrinsic tension, generated by the collagen network and the interspersed hydrophilic proteoglycan aggregates, that gives the tissue its unique resilience and resistance against both compressive and shear loading. In this sense, cartilage is by far the most challenged tissue of the three as it is not only loaded in various directions but it also must transmit the same forces while still being resilient, so without having recourse to the solution of rigidity. In the perception of the term “tissue engineering” the word “engineering” often has a connotation of “fabricating”, “producing” or “making”. That is fine for organoids, but in musculoskeletal tissue engineering the word “engineering” should be interpreted differently. In civil engineering it is all about the combination of materials and their spatial arrangement or architecture to meet the mechanical demands. The Pons Fabricius in Rome that connects the left Tiber embankment to the Tiber island, constructed in 63BC and in continuous use ever since, is a good example of durable civil engineering. The architecture of the arches, taking into account loading by traffic and the forces generated by intermittent flooding of the river, together with solid material choice gave the structure its impressive durability. In living beings the situation is not essentially different. Nevertheless we often tend to forget especially the architecture, even where we are well aware of the fact that this architecture is essentially loading driven during development. That has been known for long in bone [1], but it applies to articular cartilage too [2]. It was Benninghoff who described the essence of the architecture of the collagen network of articular cartilage already almost a century ago [3]. However, where articular cartilage tissue engineering has strongly focused on production of the major extracellular matrix components (proteoglycans and collagen type II), architecture has been largely neglected. As biological engineers we’re far yet in terms of durability from the achievements of the Roman civil engineers, but are fortunate that our durability goal is not more than a lifetime. We will only reach that goal, though, if we take into account that in tissue engineering of musculoskeletal tissues the same applies as in civil engineering: it is all about the mechanics and they are dictated by components and architecture.

REFERENCES
Supramolecular gels made of peptide amphiphiles (PA) are close biomimics of the extracellular matrix (ECM) at functional and structural level. On one hand, PA represent the targeted bioinformation of ECM proteins through the incorporation of specific aminoacid sequences. On the other hand, the PAs are designed to generate nanofibers via non-covalent interactions (i.e. Pi-Pi stacking, hydrogen bonding and hydrophobic effects). These nanofibers can further generate hydrogels that are stable under physiological conditions and stimuli responsive (e.g. pH, temperature). Despite the advantages that these systems have, supramolecular hydrogels generated by one type of PA lack chemical diversity and functional complexity present in the ECM. [1] As an example, there is a large set of bioinformation that is added in biological systems via post-translational modifications, such as protein glycosylation. Functionalization of PAs with carbohydrates to better mimic proteoglycan has been recently proposed. [2] However, this involves a laborious synthetic work, and the conjugation of the carbohydrate can modify the PA's self-assembly propensity. Multicomponent co-assembly offers a possibility to expand the chemical complexity and diversify the functionality of the supramolecular systems without compromising the simplicity of the building blocks. [3] Thus, we developed a modular system to generate proteoglycan mimics, which is based on the combination of two different amphiphiles (modules): a PA and a carbohydrate amphiphile (CA). We explored the capacity of these amphiphiles to self-assemble and generate structures that display the biofunctionality of glycans and proteins. We observed that a PA (e.g. fmoc-FF) and a CA (e.g. fmoc-glucosamine-6-sulfate or fmoc-glucosamine-6-phosphate), if properly designed, are able to interact cooperatively and form nanofibers with a structural PA core and a functional CA shell – a structural arrangement that resembles the proteoglycans in the ECM. We proved that this system is versatile: different carbohydrates can be used to generate the outer shell of the nanofibers. The generated nanofibers can further form hydrogels at physiological conditions via supramolecular crosslinking with Ca ions from the culture medium. These supramolecular gels are non-cytotoxic and biofunctional, as demonstrated by studies with growth factors, lectins and cells. They can be regarded as mimics of the ECM at another complexity level as they mimic two of the most important classes of biomolecules present in the ECM: proteins and glycans. Using this modular system it is possible to create nanofibers and supramolecular hydrogels with different peptides and carbohydrates in a high throughput manner that can be used to mimic different proteoglycans present in the ECM. Such systems will be useful either for fundamental studies targeting proteoglycans or as scaffolds for tissue engineering and regenerative medicine.

Translation of early healing principles into implant surface design for bone regeneration
R. Tejero¹,²

Presenting Author: Ricardo Tejero, ricardo@minin.es
¹Materials Science and Surface Engineering Laboratory, BTI Biotechnology Institute (Miñano, Spain) ²Institute for Regenerative Medicine and Oral Implantology (UIRMI), University of the Basque Country (UPV-EHU, Vitoria, Spain)

Implant integration is a complex process between the implant surface and the surrounding ions, proteins, bacteria and tissue cells. Ideally, more bone-like implant surfaces with an extracellular matrix structure and composition would enable earlier implant integration and function. Typically, these biomimetic modifications consist in calcium phosphates containing oxides or coatings, with or without collagen and other non-collagenous proteins. However, these developments face limitations such as lack of structural integrity, absence of epitaxial matching, low solubility, elevated extraction and purification costs, high sourcing variability, potential immunogenicity or complex pre-processing steps that compromise their bioactivity. [1] Unsurprisingly, few if any of these developments make its way to the clinic. Rather than focusing on the final steps of bone regeneration, an alternative strategy consists in exploiting some of the principles of the early healing phases around implants.

Bone-tissue regeneration starts at implant placement with the establishment of an ionic equilibrium at the interface, modulated by the surface and the local ionic composition. Protein adsorption and exchange at this new interface ensues and commands the processes of hemostasis and inflammation. A fast stabilization of the implant within the neighboring tissues is crucial for the success of implantation. It relies on the formation of the provisional matrix: a three-dimensional network of fibrin with embedded activated platelets and growth factors. Harnessing the development of this structure at the implant surface opens up the possibility to improve angiogenesis, reduce inflammation and attract, shelter and induce the activity of osteoprogenitor cells in charge of tissue regeneration [2,3]. Herein we present our experience modifying implant surfaces with soluble bioinorganic ions with relevant roles in intra- and extracellular processes relevant for bone regeneration. We investigate how this modulates the ionic equilibrium of the interface, the protein adsorption pattern and the ultimate impact of this approach all the way down to bone-implant integration in vivo.

Several regenerative medicine approaches are currently adopted to repair small focal lesions of articular cartilage, from microfracture, widely used but highly unsatisfactory, to matrix assisted chondrocytes implantation, to allografts (primarily in the US). All these techniques, are followed by extensive rehabilitation, that in general start with early passive motion followed by limited weight bearing exercises. However, there is limited (if any) scientific evidence of how these different mechanical regimes affect cell differentiation at the defect site, cartilaginous tissue formation, and integration with the surrounding cartilage [1]. To study this process, we employed a reductionist approach based on in vitro model of cartilage repair, subjected to different loading regimens to simulate the different rehabilitation exercise sessions. Ultimately, we aim at identifying the specific effects on regeneration of each exercise regime by applying multiple combinations of mechanical stresses in order to guide the optimization of post-op rehabilitation. When devising tissue engineering solutions for larger defects, a number of other factors need to be considered. Cartilage and bone are intimately and developmentally connected in articular joints [2]. To provide effective and translatable regenerative approaches, scaffolds need to include both simplicity and complexity. Simplicity to lower the translational, regulatory barrier; complexity to provide mechanical strength, mimic the local bone and cartilage microenvironment, and support and guide cell fate and differentiation. We tuned a thermally induced phase separation (TIPS) [3] approach to produce a porous poly-L-lactide (PLLA) scaffold for osteochondral tissue engineering that meets these criteria. The overall scaffold properties are suitable for implantation, while the local topology of the porous microenvironment supports and guides specific cellular differentiation towards a chondrogenic or osteogenic phenotype.

Towards the biofabrication of complex, heterogeneous bone and cartilage structures with multiple printing technologies

R. Levato$^{1,2}$

Presenting Author: Riccardo Levato, r.levato-2@umcutrecht.nl

$^1$Regenerative Medicine Center and $^2$Department of Orthopedics, Biofabrication in Translational Regenerative Medicine group, University Medical Center Utrecht (UMCU), Utrecht, The Netherlands

Major challenges in musculoskeletal tissue engineering revolve around recapitulating the architecture, and therefore the function, of native tissues. Present strategies to treat chondral and osteochondral defects, including tissue engineering and cell implantation, prevalently result in repair tissue with poor mechanical properties, which is prone to degeneration, and can only delay the insurgence of severe pathologies like osteoarthritis. Biofabrication is opening new avenues for the restoration of impaired joints tissues. Multi-material bioprinting enables to fabricate composite structures combining cell-laden, soft hydrogels with mechanically strong polymers for structural support [1]. By the accurate 3D patterning of stem and progenitor cells with different chondrogenic potential, salient features of the native zonal and depth dependent organization of articular cartilage can be replicated [2]. Alongside hydrogel extrusion and bioprinting, different additive manufacturing technologies, such as melt electrowriting of polymeric microfibers, ceramic plotting and digital light processing lithographic printing of hydrogels [4], can be combined to create composite, cell-laden constructs that enable integration between engineered cartilage hydrogels and bone scaffolds. These bioartificial osteochondral grafts exhibit improved interfacial mechanical strength, favouring their integration in vivo. Herein, the latest development in the field of bioink printing to create zonal-biomimetic cartilage constructs will be discussed, together with the integration of multiple (bio)printing strategies (i.e. co-fabrication of hydrogels, reinforcing polymers and bioceramics), and the impact of these technologies towards the generation of fully biofabricated, high-performance engineered osteochondral grafts, with potential application for regenerative medicine.

Regulation of cartilage phenotype during MSC differentiation

R. Narcisi

Presenting Author: Roberto Narcisi, r.narcisi@erasmusmc.nl

1Department of Orthopedics, Erasmus MC, University medical Center, Rotterdam, The Netherlands

Adult mesenchymal stem cells (MSCs) are potential source of chondrogenic cells for the treatment of cartilage disorders, but loss of chondrogenic capacity during in vitro expansion and the propensity of the cartilage derived from those cells to undergo hypertrophic maturation limit their therapeutic application. In the last years, often taking inspiration from the process of cartilage and bone formation during development, we aimed to identify the factors that regulate MSC expansion and their hypertrophic maturation. What we observed highlighted the importance of the FGF, WNT and TGFβ signaling interplay during the chondrogenic differentiation processes. By manipulating the expression of the TGFβ signaling components, for example, we showed how the expression of specific ALKs (TGFβ receptors) and SMADs (TGFβ intracellular effectors) during differentiation of MSCs is essential to allow chondrogenesis to take place [1-2]. We also observed that WNT3A, specifically when added in combination with FGF2, supports extensive expansion of MSCs while maintaining their chondrogenic capacity. Interestingly, the administration of WNT3A during expansion combined with the inhibition of WNT signals during differentiation was the best strategy to prevent hypertrophy maturation and calcification in vivo [3]. More recently we identify in mir-221 an interesting regulatory molecule to stimulate chondrogenic differentiation of MSC while preventing the production of the hypertrophic marker collagen type-10 in the extracellular matrix of the generated cartilage [4]. Notably, there are evidences that mir-221 can exert part of its function by regulating WNT and TGFβ signaling. In parallel, studies we conducted on developing mouse limbs allow us to identify in the transcription factor TWIST1 (a WNT target gene) an important factor in regulating proliferative and chondrogenic capacity of MSC [5], and now a new research is on-going to understand the possible involvement of TWIST1 in hypertrophic maturation. Given our recent interest in TWIST1, we are currently using a mRNA-base strategy to sort living MSCs based on their TWIST1 expression in order to verify whether the expression of this transcription factor can be used as selection marker for MSCs with improved proliferative and differentiation capacity. In our view all the acquired knowledge will facilitate the generation of new strategies to improve the applicability of MSC-based approaches in regenerative medicine, also beyond the cartilage field.

Rejuvenation of regenerative capacity in aged cells
R. S. Tuan\textsuperscript{1,2}

Presenting Author: Rocky S. Tuan, tuanr@cuhk.edu.hk
\textsuperscript{1}Institute for Tissue Engineering and Regenerative Medicine, The Chinese University of Hong Kong, Hong Kong S.A.R., China \textsuperscript{2}Center for Cellular and Molecular Engineering, Department of Orthopaedic Surgery, University of Pittsburgh School of Medicine, U.S.A

The bio-activities of bone marrow derived mesenchymal stem cells (BMSCs) generally decline with increasing biological and in vitro culture age, possibly affecting in vivo maintenance of tissue homeostasis and regenerative application. However, the exact nature of the link between stem cell senescence and natural aging is not known. Interleukin-6 (IL-6) is a multi-functional pro-inflammatory cytokine involved in inflammation and infection responses, as well as in the regulation of metabolic, regenerative, and aging processes [1]. Our results showed that BMSCs from older donors exhibited higher level of cellular senescence as a result of replication during the process of culture expansion, and IL-6 treatment may be applied to reduce the degree of senescence with the potential as an anti-aging agent. Recently, FOXO4-DRI, a FOXO4 peptide that perturbs the FOXO4 interaction with p53, was reported to selectively kill the senescent cells through triggering apoptosis [2]. Our results showed that chondrocytes for Autologous chondrocyte implantation (ACI) exhibited a higher level of cellular senescence as a result of replication during in vitro expansion, and the treatment of FOXO4-DRI was able to selectively kill senescent cells in PDL9, which reduced the SASP in chondrocytes, enhanced their proliferation capacity, and led a cartilage formation with superior quality. In view of the encouraging in vitro results, we are currently testing the chondrogenic capacity of FOXO-DRI treated chondrocyte in rabbit model.

Progress towards a new biomimetic adhesive inspired by sea urchins

R. Santos

Presenting Author: Romana Santos, rlasantos@fc.ul.pt

1 MARE - Marine and Environmental Sciences Centre, Science Faculty of the University of Lisbon, Portugal

Most surgical adhesives are based on synthetic cyanoacrylates, fibrin, albumin/glutaraldehyde or PEG polymer but despite their availability, these products are either harmful or toxic, not biodegradable, provide low adhesive strength or have a high risk of disease contaminations. Bioadhesives, on the other hand, are a new class of biological molecules optimized over millions of years of evolution, combining high biocompatibility and biodegradability with strong adhesive forces. Being inhabitants of wave-swept shores, sea urchins rely on specialized adhesive organs, the tube feet, to move and attach to the substrate. These organs possess a proximal motile stem and a distal attaching disc. The later, encloses a duo-gland adhesive system that produces separately adhesive and de-adhesive secretions. After detachment, the adhesive remains on the substratum as a footprint, but the de-adhesive secretion is not incorporated in the adhesive, indicating that it might act as an enzyme [1]. Despite having reversible adhesion, tube feet from several sea urchin species attach with tenacities around 0.5 MPa (force per unit area), which are similar to other marine permanent adhesives and superior to commercial surgical adhesives like fibrin. Sea urchin adhesive is also effective on several substrates, with variable chemistry and roughness, re-enforcing its versatility and biotechnological potential [1]. In terms of biochemical composition, sea urchin adhesives are made of inorganic residues, proteins, sugars and lipids. Recent proteomic studies produced a list of highly over-expressed disc proteins, bringing new knowledge on the key elements involved in sea urchin reversible adhesion. Within these proteins, Nectin, was found to be not only highly expressed in tube feet discs (up to 13-fold), but is an actual component of the secreted adhesive, constituting the first report on a sea urchin footprint adhesive protein [2]. At present, the gene coding for this protein has been fully sequenced [3], and recombinant technology is being used to mass-produce soluble Nectin and test its adhesive properties and biocompatibility.

REFERENCES
In patients with chronic kidney disease (CKD) adequate renal clearance is compromised, resulting in the accumulation of a plethora of uremic solutes. These uremic retention solutes, also named uremic toxins, are a heterogeneous group of organic compounds with intrinsic biological activities, of which many are too large to be filtered and/or are protein-bound. Their renal secretion depends largely on active tubular secretion, which shifts the binding and allows for active secretion of the free fraction. To facilitate this process, renal proximal tubule cells are equipped with a range of transporters that cooperate in basolateral uptake and luminal excretion. In recent years, we and others have invested in the development of bioengineered kidneys that could potentially restore this essential function. For this, well characterized renal cells were combined with functionalized membranes. This presentation addresses these developments in the context of renal tubular clearance mechanisms for uremic toxins. Furthermore, hurdles to take before a safe implementation of bioengineered kidneys in clinics becomes a realistic option will be discussed.

Gene therapy: From the nano to the macro scale
S. A. Cryan1-5
Presenting Author: Sally-Ann Cryan, scryan@rcsi.ie
1Drug Delivery & Advanced Materials Team & 2Tissue Engineering Research Group, RCSI, Dublin, Ireland 3Trinity Centre for Bioengineering, Trinity College Dublin (TCD), Dublin, Ireland 4Advanced Materials and Bioengineering Research (AMBER) Centre, RCSI & TCD 5Centre for Research in Medical Devices (CURAM), RCSI, Dublin and National University of Ireland, Galway, Ireland

The field of tissue engineering (TE) is increasingly using biomaterial scaffolds, which are augmented with therapeutics to facilitate enhanced tissue regeneration. The formation of a “gene activated” scaffold, an advanced construct containing gene therapeutics within a 3D scaffold is recognised as a safe method to provide improved spatiotemporal control of growth factor release at a defect site via the in-situ transfection of host cells. A wide range of non-viral gene vectors are being explored for application in tissue engineering to enable the transfection of host cells with gene cargoes in a 3D environment [1,2]. The development of gene therapies from the nano- to the macro scale requires careful design, formulation and screening of the gene delivery systems with a specific focus on the molecular pharmaceutics of the nanotechnologies at a cellular level and the spatiotemporal requirements of the growth factor being delivered in the context of the clinical application of the scaffold. Overall, versatile and biocompatible gene delivery vectors which are capable of functionalising 3D scaffolds for the efficient in vivo delivery of nucleic acids are going to be critical to the successful clinical translation of gene-activated scaffolds. To this end we have developed innovative, bio-inspired gene delivery vectors in the form of star-shaped poly(L-lysine) polypeptides (star-PLLs) [3] capable of effective host cell transfection in vivo and harnessed advanced imaging tools to develop and screen these vectors. Herein, our experience in the development of this novel gene delivery vector for application in tissue engineering will be discussed.

Tissue engineering of bone - As close as we can get?
S. Hofmann
Presenting Author: Sandra Hofmann, s.hofmann.boss@tue.nl
Orthopaedic Biomechanics Group, Department of Biomedical Engineering and Institute for Complex Molecular Systems, Eindhoven University of Technology, Eindhoven, The Netherlands

Bone tissue engineering has the intent to grow bone copies in the laboratory that could be used either for bone regeneration or as model systems to study bone physiology and pathology. Bone marrow- or adipose derived derived mesenchymal stromal cells are commonly used as they have been shown to be capable to differentiate into osteoblasts and depositing a calcium phosphate rich extracellular matrix. However, real bone is more than that: there are commonly three cell types described that are essential contributors to the tissue's native function: osteoblasts, osteocytes and osteoclasts. While all three cell types are being investigated separately, co-cultures of them including their precursors and inactive forms still provide a huge challenge these days, both in terms of culturing and (quantitative) evaluation. In addition, the matrix deposited by the osteoblasts in vitro is still far from bone's hierarchical organization in vivo that contributes to bone's impressive mechanical properties. Using a large set of microscopic tools (micro-computed tomography, SEM, 3D FIB/SEM, TEM and fluorescence), combined with spectroscopic (FTIR) and molecular tools (qPCR) we show that our 3D model system develops the main features of bone by human stromal cells differentiating first into osteoblasts who further embed themselves to become osteocytes. In their right environment and when stimulated mechanically, the cells are embedded within a collagenous matrix which is mineralized with carbonated hydroxyapatite. While this system still needs the addition of osteoclasts to represent 'real' bone, it allows to study the interaction between osteoblasts and osteocytes and to invest parameters contributing to collagen mineralization in high resolution and cryogenic conditions.
Synthetic versus bio-inspired approaches for adipose tissue engineering
S. Van Vlierberghe\textsuperscript{1,2}

\textsuperscript{2}Brussels Photonics, Department of Applied Physics and Photonics, Vrije Universiteit Brussel, Brussels, Belgium

There is a clear and urgent clinical need to develop soft tissue fillers that outperform the materials currently used for adipose tissue reconstruction. Recently, extensive research has been performed within this field of adipose tissue engineering as the commercially available products and the currently existing techniques are concomitant with several disadvantages. Commercial products are highly expensive and associated with an imposing need for repeated injections. Lipofilling or free fat transfer has an unpredictable outcome with respect to cell survival and potential resorption of the fat grafts. Therefore, researchers are predominantly investigating two challenging adipose tissue engineering strategies: in situ injectable materials and porous 3D printed scaffolds. The present work provides an overview of current research encompassing synthetic, biopolymer-based and extracellular matrix-derived materials with a clear focus on emerging fabrication technologies and developments realized throughout the last decade. Moreover, clinical relevance of the most promising materials will be discussed, together with potential concerns associated with their application in the clinic.
Use of electrical stimulation for tissue engineering
S.H. Cartmell

Presenting Author: Sarah Cartmell, sarah.cartmell@manchester.ac.uk

School of Materials, The University of Manchester, UK

The growth of new bone tissue in vitro requires a variety of different factors that need to be controlled and optimised. One of these factors that has previously not been considered for bone tissue engineering is electrical stimuli. Given that bone is piezoelectric in nature, it is feasible to assume that local electrical regimes have an effect on osteogenesis. There are clinical products currently on the market that deliver electrical currents locally via a cathode to fracture sites. These products demonstrate significant clinical improvements in bone repair. We have recently designed a variety of different bioreactors to both house the developing tissue and also control the applied electrical stimuli in either capacitive or direct contact methods to in vitro cultures. These bioreactors have enabled us to assess the potential use of this stimuli for in vitro bone tissue engineering purposes. It has also allowed us to further study the mechanism by which the activity of primary human mesenchymal stem cells are altered both in terms of cell proliferation and differentiation. A novel finding of the importance of the faradic by product of H$_2$O$_2$ proximal to the cathode as result of the direct electrical stimulus will be presented and its subsequent role in influencing primary mesenchymal stem cell proliferation. The morphology of primary cilia on these cells after electrical stimulation has been applied will also be discussed, in addition to the effect of varying electrical regime on cell response.

Implementing design control for 3D printed patient specific resorbable implants: From concept to clinic
S.J. Hollister

Presenting Author: Scott J. Hollister, scott.hollister@bme.gatech.edu

1Center for 3D Medical Fabrication and the Tissue Engineering and Mechanics Laboratory, Department of Biomedical Engineering, Georgia Institute of Technology, Atlanta, GA USA

Resorbable scaffolds delivering biologics has been a cornerstone of regenerative medicine research for over three decades, promising personalized medicine in the form of patient specific reconstructive approaches. However, translation of this research to clinical care, even resorbable materials alone minus biologics, has occurred at an extremely slow pace. This is due in part to the economics of manufacturing patient specific devices and in part due to the regulatory requirements that must be addressed to achieve clinical translation. This is especially difficulty in academics given the model of academic research is orthogonal in many ways to the steps necessary for translation. Specifically, regulatory bodies like the FDA require all device development be done in a design control framework that is a centerpiece of quality control. There are, however, few published examples of academic design control approaches. In this talk, we present an example of design control process for a 3D printed patient specific resorbable device that has been implanted in 17 patients to date from follow-up from 2 to 90 months[1, 2]. In this talk, we first outline the design control components required for any device: user needs, design inputs, design process, design outputs, design verification and design validation[3]. We then detail how we have implemented each design control component for the airway splint, from developing user needs to design validation in clinical use. We specifically focus on challenges in the design control process that result from patient specific devices created through 3D printing, including the increased use of computational modeling to assess devices to specific batch testing of 3D printed devices to assess manufacturing quality of the 3D printing process. We then suggest a template that can be used as a basis for design control of general 3D printed patient specific resorbable devices, including how this design control template can fit into a general quality control process. Finally, we relate clinical results in patients reported to date with device design requirements.

1Murdoch Children’s Research Institute, Royal Children’s Hospital, Parkville, Australia 2Department of Paediatrics, University of Melbourne, Australia

Genetic skeletal disorders are a significant disease burden. The lifelong disabilities suffered by patients, which range from short stature and precocious arthritis to severe bone fragility and premature death, make these an important clinical and societal problem in their own right, but they also offer insights into more common conditions such as osteoarthritis and osteoporosis. Although many genes and mutations underlying genetic skeletal disorders have been defined, our knowledge about the cellular and extracellular pathological mechanisms is incomplete, and is likely to be disease and mutation specific. A major challenge to advancing effective therapies that appropriately target disease mechanisms has been developing accurate human in vitro disease models that can be used to fully define the molecular pathology and are suitable for drug screening. A powerful emerging approach is using induced pluripotent stem cells (iPSCs) and differentiating them into chondrocytes to produce in vitro cartilage, or into osteoblasts to model bone disease. This innovative “disease in a dish” approach is driven by the importance of studying patient-specific mutations in the context of the affected human skeletal tissues. This has not been possible previously because cells from human bone and cartilage are not readily accessible and are therefore only ethically available in rare cases if a patient undergoes surgery. We have developed and optimised iPSC differentiation protocols to model cartilage and bone disorders caused by mutations in COL1A1, COL2A1 and TRPV4 and are using them to define mutation specific pathogenic pathways and, ultimately, test candidate drugs.

A clinical perspective on the future of natural polymer-based regenerative medicine
S. Shah
Presenting Author: Siegfried Shah, siegfried.shah@ct-west.de
Department for General and Abdominal Surgery, St. Marien Hospital Dueren, Dueren, Germany

Since disciplines like Tissue Engineering (TE) and Regenerative Medicine (RM) are getting more into the focus of interventional clinicians and surgeons the demand for biodegradable and bioresorbable polymer-based biomaterials fulfilling highest biocompatibility requirements and including tuneable mechanical properties for specific applications is strongly increasing.

Such polymer-based biomaterials can be of synthetic or natural origin. The synthetic, non-degradable polymers PTFE (VascuGraft® SOFT), PET (Vascutek®) and the synthetic, degradable polyesters PLA (Absorb™ BVS) and PGA (Valtrac®) are giving relative positive and negative clinical examples as well. In case of regenerative medicine approaches clinicians are dreaming of shifting post-pathological situations in the healing phases from reparation to more “restitutio-ad-integrum”, which means true regeneration. Natural polymers like fibrin, collagen, polysaccharides (e.g. hyaluronic acid, alginate) are typical candidates, but comprise several disadvantages in case of their application to regenerative medicine. A very promising class of natural polymers are the polyhydroxyalkanoates (PHAs), biotechnologically synthesized in bacteria. Many of them are “biocompatible”, s.th. which is still under critical evaluation with a very promising perspective for some of the PHA candidates. Additionally, their mechanical properties are highly tuneable and thereby a very good processability is given. More specified potential application areas for PHA-based biomaterials are regenerative wound dressings, biodegradable and -resorbable enteral anastomosis stents and in situ-regenerative vascular grafts to name only a few. Finally, we are convinced that not every natural polymer is a promising biomaterial for regenerative medicine applications. But amongst different types of natural polymers the PHAs have a huge potential for translational regenerative approaches.
Versatile crosslinked gelatin hydrogel for regenerative medicine applications
S. Farè
Presenting Author: Silvia Farè, silvia.fare@polimi.it
Department of Chemistry, Materials and Chemical Engineering “G. Natta”, Politecnico di Milano, Milan, Italy & National Interuniversity Consortium of Materials Science and Technology (INSTM), Florence, Italy

Gelatin is widely investigated in regenerative medicine for its solubility in water, lower antigenic and immunogenic response compared to collagen, readily availability, and exposure of cell-binding motives and metalloproteinase target-sites for degradation. Crosslinking is necessary to produce gelatin hydrogels stable at 37 °C. In this work crosslinking is based on a Michael-type addition between gelatin and methylenebisacrylamide, the crosslinker. Gelatin concentration and reaction stoichiometry were varied to tune hydrogels chemico-physical and mechanical properties. All the produced hydrogels were stable in water at 37 °C, proving the efficiency of the crosslinking reaction; different mechanical and rheological properties were exhibited, as well as the in vitro cell activity. Using sacrificial alginate microbeads and 3D printed structures a porous gelatin hydrogel with a controlled vasculature was obtained. The so-produced scaffolds showed good porosity, mechanical compressive response, and enzymatic degradability. The hollow channels allowed fluids flow and cells adhesion to the hollow channels walls, promising aspects for a promoted vascularisation. Microspheres for cell and drug delivery were prepared in a controlled dimension range (40–135 μm). Metabolic activity of cells on the microspheres increases up to 14 days of incubation and Live/Dead staining showed vital cells on the surface of the MSs and a reduced presence of dead cells. A preliminary study showed the possibility to spray the microspheres with cells or loaded with drug, representing an innovative and possible approach. In conclusion, the versatility of the innovative crosslinked gelatin hydrogels was demonstrated by using advanced fabrication technologies.
Innovation and commercialisation in the field of regenerative medicine: Learning from the past and lessons for the future
S. Champ
Presenting Author: Simon Champ, simon.champ@bellaseno.com
1BellaSeno GmbH, Deutscher Platz 5a, 04103 Leipzig, Germany

The resources required to develop and market a regenerative therapy are substantial, as is the time to market, and the risk of failure is high. However, the potential benefits, both social and financial, of regenerative medicine are enormous. Turning this potential into reality will be challenging and companies need to develop and implement innovative business strategies in order to succeed. In this presentation, business strategies, market and competitive environments will be discussed in the context of several case studies of successful as well as unsuccessful companies in the field of regenerative medicine. A number of important lessons from these cases shall be discussed. From a management perspective the most critical lesson is the importance of effective financial planning and management of costs, and in particular R&D costs, including the significant costs associated with clinical trials. In addition, a clear strategic focus is extremely important due to the significant resources required in the development of a new therapy. From an investor’s perspective the lessons to be gathered from the case studies are related to the risk involved in investing in the field of regenerative medicine. The importance of a clear and focused strategy based on long-term investor commitment shall be emphasised for the successful commercialization of regenerative medicine products.

Recent developments to utilize induced pluripotent stem cells for cartilage regeneration
S. Diederichs

Presenting Author: Solvig Diederichs, solvig.diederichs@med.uni-heidelberg.de

1Research Center for Experimental Orthopaedics, Center for Orthopaedics, Trauma Surgery and Paraplegiology, Heidelberg University Hospital, Heidelberg, Germany

As a potential non-invasive cell source for a large amount of chondrocytes, induced pluripotent stem cells (iPSCs) are highly attractive for cartilage regeneration. This field currently lacks an optimal cell source, because the only applicable cells—autologous chondrocytes—are highly invasive to harvest and extremely limited in number. Although mesenchymal stromal cells (MSCs) from bone marrow or adipose tissue have been hoped to overcome cell shortage, they differentiate along the endochondral pathway when induced into chondrocytes in vitro and develop an inherent mineralization activity leading to bone formation at ectopic sites. iPSCs promise to overcome both these limitations, since they possess a virtually unlimited expansion capacity and are intrinsically capable to form any adult tissue including stable hyaline cartilage. Their primitivity, however, makes in vitro differentiation of iPSCs into chondrocytes highly challenging. So far, varying methods have been reported and there is currently no generally accepted standard protocol. A common basis for many attempts is to recapitulate embryonic cartilage development. This requires sequential induction of multiple developmental phases and, thus, production of an intermediate phenotype representing a metastable state of mesenchymal progenitors. These progenitors are subsequently induced into the chondrogenic lineage. We and others have shown that such iPSP-derived mesenchymal progenitor cells (iMPCs) resemble MSCs by expressing a similar surface marker profile and a general capacity for in vitro differentiation into the three mesenchymal lineages (cartilage, bone, fat) [1]. Yet, in direct comparison with MSCs, striking differences became apparent, including their inducibility to differentiate in vitro [2] and their DNA methylation pattern which indicated that iMPCs have a juvenile rather than an adult stem cell activity. Here, current concepts for iMPC generation and chondrogenic differentiation will be discussed and specific characteristics, efficiency, reproducibility and robustness will be compared with MSC chondrogenesis. Moreover, potential applications beyond cell therapeutics for cartilage regeneration as well as clinical safety aspects will be highlighted.

Advanced formulations based on multifunctional mesoporous glasses for highly targeted therapies in tissue regeneration
S. Fiorilli
Presenting Author: Sonia Fiorilli, sonia.fiorilli@polito.it
Applied Science and Technology Department, Politecnico di Torino, Italy

In the field of bioceramics, mesoporous bioactive glasses (MBGs) have received significant interest in the past decade as powerful bone regeneration systems. However, in the presence of compromised remodelling process (e.g. delayed bone healing, osteoporosis), the effective treatment of bone defects still represents a challenging clinical issue. In addition, for these compromised clinical situations, the risk of bacterial infections is very high and increases the number of unsuccessful therapies. To address this challenge, the design of novel and multifunctional MBG formulations able to synergistically combine the biological functions of specific therapeutic elements (pro-osteogenesis, pro-angiogenesis and bactericidal effects) with bacterial anti-adhesive properties would represent a big step towards timely and effective therapies. In addition, due to their well-defined and accessible porous structure MBGs are able to store and release different drug molecules (i.e. anti-inflammatory, anti-oxidant and antibiotic agents) and their surface functionalization can impart stimuli-responsive and/or specific targeting properties. In this contribution, SiO$_2$-CaO MBGs containing therapeutic elements (i.e. Sr, Cu) were prepared in the form of nano- and micro-particles, and functionalised through different routes (i.e silane chemistry, polymer grafting) to provide their surface with anti-adhesive properties, in order to prevent bacteria attachment and colonization. The ion/drug release properties of functionalized MBGs have been assessed and the obtained multifunctional systems incorporated into a vehicle phase based on a thermo-sensitive polymer to design an injectable device for prolonged and localised release.
Towards the development of a biohybrid lung

S. Korossis¹,²
Presenting Author: Sotiris Korossis, s.korossis@lboro.ac.uk
¹Lower Saxony Centre for Biomedical Engineering Implant Research and Development, Department of Cardiothoracic, Transplantation and Vascular Surgery Hannover Medical School, Hannover, Germany ²Cardiopulmonary Regenerative Engineering (CARE) Group, Centre for Biological Engineering, Loughborough University, United Kingdom

Lung disease is the third largest cause of death, behind cardiovascular disease and cancer. In the US alone, 35 million patients suffer from chronic lung disease, with a yearly fatality rate of nearly 340,000 patients [1]. Chronic obstructive pulmonary disease (COPD) and acute respiratory distress syndrome (ARDS) are two of the most common respiratory conditions worldwide. Currently, end-stage and chronic lung disease can only be treated by lung transplantation. However, the low donor lung availability and patient ineligibility limit the number of worldwide lung transplantations to below 1,500 per year [2], whereas the waiting time and death rate of the patients in lung transplantation lists is >14 months and 11.3%, respectively. Moreover, the half-life survival after lung transplantation is about 5.4 years [3]. Patients with irreversible lung disease have no reliable bridge-to-transplantation option, having a poor quality of life, often confined in intensive care units (ICUs). Current therapies used for respiratory failure include mechanical ventilation, and artificial lung devices, such as extracorporeal membrane oxygenation (ECMO) and lung assist (ECLA) for decarboxylation. Mechanical ventilation offers effective short-term support, but is associated with barotrauma, volutrauma and other injuries, further exacerbating respiratory deficiency. Artificial lung devices provide respiratory support independent of injured lungs and allow them to rest and heal. ECMO and ECLA are established therapeutic tools in modern ICUs, and are primarily employed as short-term bridges to transplantation. Although these systems are attractive due to simulating physiological decarboxylation/oxygenation, they are limited by the complexity of operation, reduced patient mobility, thrombosis and associated thromboembolism, plasma weeping through the membrane pores, flow-path-induced blood trauma, and inflammatory reaction due to direct contact of blood with artificial components. These complications limit artificial lung usage to between 4-6 weeks and in specialized ICUs. The development of a fully-haemocompatible and partially- or fully-implantable artificial lung that can be used as a longer-term bridge to transplantation or a destination therapy, and allows ambulation and hospital discharge, could significantly improve the prospects and quality of life of patients. In the past few years, artificial lung endothelialization has emerged as a promising alternative for providing a natural barrier between the artificial gas-exchange membranes and the patient’s blood. In this talk, our experience with the functionalisation, endothelialization and haemodynamical optimization of hollow-fiber membrane oxygenators will be discussed.

1Department of Plastic, Reconstructive Surgery, University Hospital Basel, Spitalstrasse 21, 4021, Basel, Switzerland 2Department of Biomedical Engineering, University of Basel, Gewerbestrasse 14, 4123 Allschwil, Switzerland

Peripheral nerve injuries affect more than one million people each year and often result in life-long disabilities due to lack of efficient therapeutic options. Currently available treatment options are associated with several drawbacks and lack the ability to provide dynamic microenvironment required for axonal path finding following injuries. Here, we report on bioengineered nerve conduits addressing both trophic and topographical requirements of adult axonal regeneration. For this, we generated genetically enriched Schwann cells for delivering multiple neurotrophic factors with discrete release kinetics. Resulting Schwann cells, proved to be viable and efficacious both in vitro and in vivo in a nerve injury model. Further, collagen or silk fibroin based nerve conduits scaffolds with controlled nano-topography were fabricated using a novel technique and repopulated with genetically enriched Schwann cells. Resulting conduit scaffolds varying in trophic and topographical functions were studied in 10 mm nerve gap model in rats. The anatomical and functional outcomes differed significantly among the various animal groups. Furthermore, serum analysis indicated absence of undesired immune response against the genetically modified Schwann cells. Importantly, bioengineered collagen and silk fibroin NCs carrying most important biological functions showed potential to overcome the present hurdles of nerve regeneration and achieved the level of autograft performance. This study not only revealed the important role of trophic and topographical functions for effective axonal regeneration, but also demonstrated the impact of biomaterial composition in mounting selective axonal growth response.

Microfluidic systems for in vitro morphogenesis models
S. Giselbrecht

Presenting Author: Stefan Giselbrecht, s.giselbrecht@maastrichtuniversity.nl
1MERLN Institute for Technology-Inspired Regenerative Medicine, Maastricht University, Maastricht, The Netherlands

Tissue patterning and organogenesis are key processes in a developing embryo, which are tightly regulated by autonomous and non-autonomous mechanisms. Several of these underlying mechanisms have been elucidated in the past, but numerous details remain still elusive. Various research groups have recently shown that under certain conditions aspects of early embryonic patterning, such as symmetry breaking and germ layer specification, can be recapitulated in vitro. [1] Stem cell-derived, embryo-like entities, so-called ‘synthetic embryos’, were created by a bioengineering approach that will help us to shed more light on essential cell-cell interactions in the embryo and to study mechanisms of implantation in future. [2] We are focusing on the development of non-adherent cultures of pluripotent stem cell aggregates in microfluidic systems to study early embryonic patterning, such as collective cell migration and axis formation. The systems allow us to observe and manipulate developmental phenomena on a cellular level which normally occur in vivo within the uterus, making them difficult to study. The heart of our technology platform is based on our proprietary ‘substrate modification and replication by thermoforming’ (SMART) technology. This technology is used to fabricate functionalized polymer film-based microcavity arrays to control cell patterning and differentiation in embryoid bodies under static and actively perfused 3D cell culture conditions, e.g. by integrating them into microfluidic bioreactors. We used these microcavity arrays for studying the effects of various parameters including cell seeding density, fluid flow, and microcavity size and shape in order to increase control and reproducibility of pattern formation processes. Our results showed an influence of microcavity dimensions and the rate of refreshing medium on patterns of paracrine signals secreted by cells (COMSOL simulations), which might influence patterning events in 3D in vitro morphogenesis models. We also showed that some of the in vitro morphogenesis models can be cultured in microcavity-based systems in a high-throughput manner. Further, the degree of (axis) elongation and orientation in pluripotent stem cell aggregates can be controlled by changing the size of the microcavities. The development of innovative microfluidic tools in this new research area, also called ‘Morphogenetic Micro Engineering’, will allow us to interfere and eventually control pattern formation in well-described in vitro models of developmental biology and will help us to gain deeper insights into the mechanisms underlying organogenesis. [3] In future, this, in turn, will facilitate us to develop new and more sophisticated tools for biomedical applications and to improve regeneration in adult organisms.

Department of Chemical and Biological Engineering, University at Buffalo, State University of New York, USA

Cardiovascular disease is the leading cause of mortality worldwide. Regarded as the therapeutic gold standard, treatment with autologous grafts suffers from several technical and patient-related risks. Tissue engineered small diameter blood vessels may provide a promising alternative solution as replacement grafts. In this study, we employed adult and induced pluripotent stem cells to engineer fully functional vascular grafts that were implanted into the arterial circulation of a physiologically relevant ovine animal model, where they remained patent and underwent successful remodeling. In addition, we engineered cell-free (off-the-shelf) vascular grafts that were implanted successfully into the arterial system of adult as well as neonatal sheep. Most notably, as the animals grew, the grafts increased in size (length and diameter), demonstrating their potential application for treatment of congenital pediatric disorders. During the course of our studies using mesenchymal stem cells (MSC) to engineer vascular grafts, we observed MSC originating from older donors suffer from limited proliferative capacity and significantly reduced myogenic differentiation potential. This is a major concern, as the patients most likely to suffer from cardiovascular disease and therefore in need of vascular grafts are elderly. Notably, we developed a strategy to reverse the proliferation and differentiation potential of MSC from adult donors as well as to restore of ECM synthesis and contractile function. In addition to MSC, we demonstrated that our strategy could “rejuvenate” senescent skeletal muscle cells (SkMC) and identified molecular pathways that are involved in this process. Our work demonstrate the potential of molecular engineering strategies to reverse the effects of organismal aging and restore the potential of adult stem cells for use in cellular therapies and tissue regeneration. In the second part of my presentation, I will focus on deriving neural crest stem cells (NC) and their derivatives from neonatal and adult epidermis. NC cells are induced by signaling events at the neural plate border during development of vertebrate embryos. Initially arising within the central nervous system, NC cells subsequently undergo epithelial-to-mesenchymal transition and migrate into the periphery, where they differentiate into diverse cell types. We discovered that NC can be derived from postnatal human epidermal keratinocytes (KC) without genetic modification or reprogramming to the pluripotent state. Genome-wide transcriptome analyses showed that KC-derived NC cells are similar to NC cells derived from human embryonic stem cells. Moreover, KC-NC give rise in vitro and in vivo to NC derivatives such as peripheral neurons, melanocytes, Schwann cells and mesenchymal cells (osteocytes, chondrocytes, adipocytes, and smooth muscle cells). Lineage tracing studies by implantation of KC-NC into chick embryos confirmed the NC phenotype of these cells in an in vivo setting. This work represents a paradigm shift as it demonstrates that the epidermis is a novel source of abundant, readily accessible, autologous stem cells for treatment of neurodegenerative diseases, for which cell sourcing remains a severe impediment hampering cell therapy approaches.
Development of adipose stem cell-based approaches for intervertebral disc regeneration and treatment of low back pain

S.M. Richardson
Presenting Author: Stephen M. Richardson s.richardson@manchester.ac.uk
Division of Cell Matrix Biology and Regenerative Medicine, School of Biological Sciences, Faculty of Biology, Medicine and Health, University of Manchester, Manchester, United Kingdom

Low back pain (LBP) represents one of the leading causes of disability in the Western world, affecting over 80% of the population at some during their lifetime. In the majority of cases intervertebral disc (IVD) degeneration is the cause of LBP. Current treatments for LBP associated with IVD degeneration offer poor long-term efficacy and this has led to an increasing interest in the development of cell-based regenerative therapies. IVD degeneration originates in the central nucleus pulposus (NP) region, where increases in proinflammatory cytokines drives a catabolic phenotype in resident NP cells leading to degradation of the aggrecan and type II collagen rich matrix. We have focussed on the development of adult stem cell-based approaches for NP regeneration and compared the anti-inflammatory and regenerative potential of human donor-matched bone marrow mesenchymal stem cells (MSCs) and adipose stem cells (ASCs). Here I will discuss our recent findings on the anti-inflammatory properties of MSCs/ASCs, their directed differentiation to NP cells (specifically with the growth factor GDF6), and the signalling mechanisms which underpin these responses. I will also discuss the development of biomaterials to deliver growth factors and support implanted cells within the harsh microenvironment of the degenerate IVD, which will enable future clinical translation of the next generation of regenerative therapies for IVD degeneration and associated LBP.
Hydrogels that support cell adhesion

S. Rimmer

Presenting Author: Stephen Rimmer s.rimmer@bradford.ac.uk

Polymer and Biomaterials Chemistry Labs., School of Chemistry and Biosciences, University of Bradford, Bradford, West Yorkshire, BD1 7DP, UK

Hydrogel materials provide the closest match to the physical properties of the extra-cellular matrix. However, this is obtained because of their high-water content and this high degree of swelling produces materials that are very non-cell adhesive. In natural systems this allows for specific cell-adhesion interactions without general and non-specific adhesion. Chiefly, interactions between extracellular proteins and integrins provide the signals for adhesion. Amine functional surfaces have been studied as charged modifications of biomaterials for improving cell adhesion. However, only recently have we realized that alkyl primary amine functionality can provide interfaces that are highly selective for epithelial cells.1 In this initial work on human corneal epithelial cells we had assumed that coculture with stromal cells would be required as is in traditional in vitro culture. However, later we showed that culture of the epithelial cells alone was successful and that these hydroxylated hydrogels with alkyl primary amine-functionality were, in fact, poor substrates for fibroblasts.2 Extensive assessment of these 2D culture substrates showed that they did not initiate a significant response from murine peritoneal macrophages; giving them potential as implantable materials to enhance wound healing. With this in mind we showed that implantation in an explanted corneal model supported the re-epithelization of the cornea.4 To be useful as supports for epithelial cells these hydrogels require functionalization with primary amines; secondary and tertiary amines do not support epithelization. It is necessary to attach the amine via an alkyl chain of at least 3 methylene units. The materials do not support chondrocytes, MSCs or osteoblasts. Finally, protein adsorption experiments showed that there was little difference in general protein adsorption between non-adhesive hydrogels (not alkyl primary amine-functional) and cells adhesive hydrogels (alkyl primary amine-functional). These observations indicated a possible enzymatic mechanism and given that a primary alkyl amine interface has the same functionality as lysine units on collagen it seems reasonable to provide the hypothesis that tissue transglutaminases can modify these interfaces during culture to provide an interface that can support these cells. Another approach used by us and many others has been to functionalize hydrogels with integrin binding peptides. A new approach adopted by us is to prepare peptide functional polymers that can blended into hydrogels during manufacture. To do this we have developed semi-interpenetrating hydrogel networks in which the soluble component is branched. The use of polymeric additives in this has major advantages in processing because they can be easily dosed into production procedures such as additive manufacturing. The use of branched polymers with peptide end groups (GRGDS in this case) allows for maximum availability of the peptide ligands and the branched architecture ensured that the functional polymer cannot be leached from the network.

3D bioprinting iPSCs to recapitulate human limb bud development - An osteoarthritis disease model
S. Simonsson

Presenting Author: Stina Simonsson, stina.simonsson@gu.se

1Institute of Biomedicine, Department of Clinical Chemistry and Transfusion Medicine, University of Gothenburg, Sweden

Cartilage lesions that can develop into degenerated osteoarthritis (OA) cartilage are a worldwide burden. As a prospective treatment for such lesions, we have previously shown that human-derived induced pluripotent stem cells (iPSCs) can be 3D bioprinted into cartilage-mimics [1]. The advantages by using an established iPSC line developed from chondrocytes are unlimited, immortal characterized cell source with a differentiation bias towards cartilage [2]. Designing protocols that generates hyaline cartilage from pluripotent cells in vitro is still a challenge, due to that joint formation are late in development and far from the pluripotent state. There are recent protocols for hyaline-like cartilage generation from iPSCs. Herein our 3D differentiation of bio-printed iPSC line experience that resemble limb bud formation (Figure 1) will be discussed.

Figure 1: Limb bud like condensed structures are formed after in vitro differentiation of iPSCs.

Inflammation and bone regeneration
S. B. Goodman
Presenting Author: Stuart B. Goodman, goodbone@stanford.edu
Department of Orthopaedic Surgery and Bioengineering, Stanford University, Stanford, CA, USA

Inflammation is the first stage of tissue healing and regeneration after traumatic injuries, exposure to infectious agents, and other adverse stimuli. If the natural sequence of events comprising tissue healing is interfered with or dysregulated, repair and regeneration of host tissue is impaired. Furthermore, if the injurious stimulus is not quickly mitigated or completely extinguished, either the organism as a whole will succumb (if the injury or response is overwhelming), or the local tissues will progress to a state of chronic inflammation, in which ongoing injury and attempts at repair persist. In the context of orthopaedic surgery, we have studied important interactions among cells of the innate immune system, i.e. the monocyte-macrophage-foreign body giant cell-osteoclast lineage, and the mesenchymal stem cell (MSC)-osteoblast lineage using in vitro and in vivo models. Based on this work, we have confirmed several important principles that underlie how bone is formed, destroyed and remodelled, that are applicable to the engineering of new bone. First, for optimal bone repair, the inflammatory phase of healing cannot be omitted. Second, there exists a definite period of time for the inflammatory phase to occur; shortening this time period mitigates bone healing. Third, during the initial inflammatory phase, pro-inflammatory cytokines and other macrophage-derived molecules precondition MSCs to be more efficient at bone formation. Fourth, if chronic inflammation occurs, the timely introduction of an anti-inflammatory cytokine such as IL-4 by direct infusion, release from a scaffold or via genetically modified MSCs can be effective in quenching inflammation and facilitating bone formation.
Cells and non-cellular players compose cancer microenvironment. In particular, cancer cells interact with fibroblasts, mesenchymal, endothelial and immune system cells. Extracellular matrix (ECM) supports cancer progression, migration and metastasis. Biomaterials are engineered for different matrices for cell-based tissue regeneration as they satisfy most of the qualities of ideal scaffolds. Solid evidences have shown that these protein/polysaccharides-based matrices support the growth, viability and proliferation of various mammalian cell lines and the differentiation of primary cells. Biomaterials can easily be functionalized according to the target application, in particular cancer modelling and therapeutic screening [1]. Three-dimensional cell culture is employed to achieve a comprehensive understanding of the molecular mechanisms underpinning cancer development [2]. In this work, different experimental approaches are used to develop 3D tumor models (breast, bone and lung). Naturally-derived polysaccharides (gellan gum), hyaluronic acid or proteins (silk and collagen) are employed to mimic the tumor microenvironment. The surfaces are designed using hyaluronic acid being a component of ECM for mimicking the extracellular microenvironment of cancer cells. The crosstalk between cancer cells, fibroblasts, stem cells and endothelial cells is reproduced in the 3D cancer models, to mimic the tumor microenvironment. The blended hydrogels composed of silk/gellan gum are developed with different ratios, to modulate the capability of bone cancer cells to self-organize into spheroid-like structures. The interaction between stem cells and osteosarcoma cells is investigated using blended silk/gellan gum freeze-dried hydrogels. Moreover, silk fibroin freeze-dried scaffolds are characterized in terms of porosity and porous interconnectivity. Silk fibroin scaffolds are used as ECM models to seed breast cancer cells (MCF-7) and normal mammary fibroblasts. The 3D microtumor tissues are analyzed using biochemical assays (alamar blue, live-dead, DNA quantification), microscopic techniques (phase-contrast, confocal and SEM), gene analysis, histology, immuno-histochemistry. The 3D microtumors are used as testing platform for anti-cancer drug compounds, in particular doxorubicin. Finally, lung cancer (A549) and endothelial (EA.hy926) cells are incorporated into a tumor-on-chip microfluidic device leading to a more realistic model to investigate intravasation. Time-lapse microscopy is used to monitor the role of protrusions in the mechanism of invasion, and the effect of doxorubicin and Rho inhibitor (C3 transferase) in tumor dissemination is investigated. These results shed light on the mechanisms of cancer development, invasion and strategies to treat the disease.

New approach to regeneration of osteochondral defects by using Agili-C cell-free scaffold
S. Chubinskaya
Presenting Author: Susanna Chubinskaya, susanna_chubinskaya@rush.edu
Department of Pediatrics, Rush University Medical Center, Chicago, IL 60612, USA

The Agili-C™ is a first-in-class acellular implant designed for simultaneous regeneration of cartilage and subchondral bone. Here we provide the evidence of the ability of human adult articular chondrocytes to migrate from cartilage explants into the Agili-C™ scaffold forming hyaline-like cartilage. Normal cartilage was collected from the knee and ankle joints of 13 human donors. The chondral phase of the implant was placed inside donut-shaped cartilage plugs and cultured in 20% serum. Chondrocyte survival, migration, PG synthesis, histology, and collagen II and aggrecan gene and protein expression were used to characterize cellular responses and confirm hyaline-type structure. The data were analyzed with two-tailed t-test comparing the mean of samples cultured with Agili-C™ construct to the mean of control. The P values <0.05 were considered statistically significant. Chondrocyte migration into the Agili-C™ constructs was independent of the joint, gender or donor’s age. Cells remained viable inside 3D construct and deposited ECM enriched in collagen II and aggrecan. By day 60, PG synthesis was 3-fold higher, Agg gene expression was 4-fold higher (p<0.0001) and ColII gene expression was 8-fold higher (p<0.001) respectively in explants containing Agili-C™ (p=0.007) in comparison with control. Additionally, we showed a layer formed on the surface of the implant populated by progenitor-like cells. Concluding, the Agili-C™ implant is capable of inducing hyaline cartilage evidenced by the expression of specific markers and appropriate structural organization suggesting a migration and proliferation of chondrocytes and progenitor cells from the periphery and the surface of the tissue with the formation of ECM.
Immunocompetent skin models to emulate sensitation and allergy formation
S. Gibbs¹,²

Approximately 15-20% of the general population have Allergic Contact Dermatitis (ACD) resulting from environmental chemical exposure, making this skin disease a major health problem. Development occurs in two phases: in the first (induction) phase exposure to a chemical allergen causes immunological priming known as skin sensitization. The second (elicitation) phase is triggered if a sensitized person is again exposed to the same allergen. Therefore, prevention of ACD should be prioritized, warranting extensive efforts into understanding the cellular mechanisms of sensitization in order to identify sensitizers, predict the potency of a sensitizer and most importantly to predict the safe (no response) concentration of a potential sensitizer. This has led to an adverse outcome pathway for sensitization which identifies the 4 Key Events: Key Event 1 – chemical penetration through the skins stratum corneum; Key Event 2 – keratinocyte activation (cytokine secretion); Key Event 3 – antigen loaded Langerhans cell (LC) maturation and migration from epidermis to dermis and then to lymph nodes; and Key Event 4 - antigen presentation by LC to antigen-responsive T-cells in the local lymph node which results in T-cell priming (memory) [1]. Here we describe a unique reconstructed human skin model with integrated MUTZ-3 derived Langerhans Cells (RhS-LC) which enables key events 1, 2 and 3 to be investigated in a single skin model [2,3]. MUTZ-LC display similar phenotypic plasticity as their primary counterparts when incorporated into RhS. We describe differences and similarities in the mechanisms regulating LC migration and plasticity upon allergen or irritant exposure enabling contact sensitizers to be distinguished from irritants. The model therefore provides a unique and relevant research tool to study human LC biology in situ under controlled in vitro conditions, and will provide a powerful tool for hazard identification, testing novel therapeutics and identifying new drug targets. Currently the RhS-LC is being incorporated into a microfluidics device to further investigate immune mediated skin disease and systemic toxicity.

Approaching cartilage repair from several directions using pluripotent stem cells
S. J. Kimber
Presenting Author: Susan J Kimber, sue.kimber@manchester.ac.uk
Division of Cell Matrix Biology and Regenerative Medicine, Faculty of Biology Medicine and Health
University of Manchester M13 9PT, UK

Osteoarthritis (OA) affects the mobility and life-quality of millions of people worldwide with
prevalence increasing during ageing and with risk factors e.g. injury and obesity. Thus, the incidence
of OA is set to rise steeply with an ageing and increasingly obese population. Hyaline cartilage lining
the joints consists mainly of extracellular matrix containing proteins, proteoglycans, glycosaminoglycans and water, with chondrocytes making up less than 3% of the tissue volume. The
matrix produced by the chondrocytes contains region-specific orientation of collagen fibres and is
rich in proteoglycans especially chondroitin sulphate proteoglycan and hyaluronan. Aggrecan with
associated glycosaminoglycans forms the major proteoglycan. Disease and trauma of articular
cartilage result in progressive damage to this matrix. Since cartilage has poor intrinsic repair
mechanisms due to the lack of blood vessels and nerves, this damage commonly leads to OA
accompanied by pain and loss of mobility. Due to the limitations of joint replacement and restrictions
in adoption of autologous chondrocyte implantation there is an unmet clinical need to provide new
ways to repair articular cartilage. Clinical grade human embryonic stem cells (hESCs) or induced
pluripotent stem cells (iPSCs), generated under Good Manufacturing Practice (GMP) conditions, are
a promising cell source for chondrocytes. They can be maintained as an inexhaustible, expandable
cell population which retain their ability to differentiate to all body cell types. hESCs and iPSCs
can be induced to form chondrocytes using standardised protocols based on the temporal course of
signaling during mesodermal development (1) and generating cells of consistent and reproducible
repair potential. We showed that these cells can repair cartilage in an osteochondral defect in the hind
limb femoral head cartilage of immunocompromised rats (2). We refined this protocol (e.g. 3)
extended it into a 3D pellet or 3D scaffold formats in which cartilage extracellular matrix protein is
laid down in vitro. However, although the cells make increasing amounts of collagen II, until recently
they have generated only modest amounts of the major proteoglycan of cartilage, aggrecan. As
aggrecan is crucially important for cartilage compressive properties, this was a weakness in using
such cells therapeutically. In recent work we have shown that epigenetic modifiers can enhance
aggrecan formation over and above other methods such as TGFB family modulation. By histone
deacetylase activation, we achieved a 64 fold increase in aggrecan transcript with parallel
upregulation of the transcription factor SOX 5 (18fold), co-regulator with SOX9 of chondrogenic
genes. This occurred without inducing expression of COLX (indicative of pre-hypertrophic
chondrocytes) or increased COL1. We are now identifying the regulatory pathways associated with
these changes. To improve chondrogenesis in vitro further we have investigated encapsulation in
hydrogels. In collaboration with the Karperien lab (University of Twente) we have identified
hydrogels which support chondrogenesis from hESC far better than our previous scaffold, fibrin. The
results suggest that hydrogels based on carbohydrate chains may be superior to those based on peptide
gels for maturing hESC-prechondrocytes to chondrocytes and maintaining phenotype.

Bone injury response and the extracellular vesicle-mediated crosstalk between immune and mesenchymal stem/stromal cells
S.G. Santos1,2
Presenting Author: Susana G. Santos, Susana.santos@ineb.up.pt
1i3S - Instituto de Investigação e Inovação em Saúde and INEB - Instituto de Engenharia Biomédica, Universidade do Porto, Portugal 2ICBAS - Instituto de Ciências Biomédicas Abel Salazar, Universidade do Porto, Portugal

Tissue response to injury is initiated with acute inflammation, which defends the host against pathogens and prepares the injury microenvironment for tissue repair and remodelling. Coordination of the different stages requires intercellular communication, cell recruitment, proliferation, activation and differentiation. As part of their communication strategies cells secrete Extracellular Vesicles (EV), including exosomes and microvesicles. EV, and particularly exosomes, are reported to play important roles for the different stages of tissue repair and regeneration [1]. Our work has been addressing the communication between immune cells and Mesenchymal Stem/Stromal Cells (MSC), in the context of bone repair. Herein, we will discuss our results and approaches using primary human cells and a rat bone defect model. Using human primary cells, we showed that monocyte-derived Dendritic Cells (DC) can recruit MSC via paracrine action, and that EV are the main effectors of that recruitment, being enriched in chemoattractant mediators [2]. Analyzing the rat femoral bone defect model at 3 days (acute inflammation) and 14 days (inflammation resolution) after bone injury, we characterized the temporal regulation of the systemic response at the levels of immune cell populations and plasma micro(mi)RNA profile. We encountered changes in systemic immune cell populations in blood, draining lymph nodes and spleen at day 3 and a return to baseline by day 14. At the miRNA level, bone injury led to a general down-regulation of miRNA levels in plasma at 3 days, and an up-regulation of let-7 family and miR-21 at day 14 after injury. In silico pathway analysis predicted that most miRNAs temporally affected were involved in miRNA processing, cellular development, proliferation and movement [3]. Additionally, we are analyzing the impact of bone injury microenvironment on bone marrow (BM) precursors of DC and macrophages, and their EV-mediated crosstalk with MSC. Interestingly, the capacity of BM-DC-secreted EV to recruit MSC changes significantly with time after bone injury. Finally, the potential of EV as therapeutic tools, and our work on delivery strategies to preserve their biological action will be discussed.

Osteoarthritis (OA) is the most common joint disorder and the leading cause of disability and chronic pain in the elderly with a major adverse socio-economic impact. To date pharmacological interventions can only relieve pain, whilst cell- and compound based therapies have limited success in the regeneration of damaged tissues. Thus, there is a need for identification of novel targets for diagnostic and therapeutic approaches. The joints are innervated by calcitonin gene-related peptide (CGRP) - and substance P (SP) positive sensory nerve fibers which are a potential source of tibial-femoral pain during OA pathogenesis. Alteration of sensory joint innervation might be partly responsible for degenerative changes that contribute to development of OA [1-3]. OA was induced in wildtype (WT), SP-knockout (Tachykinin1-/-) and CGRP-knockout mice by surgical destabilization of the medial meniscus (DMM). The medial subchondral bone structure was analyzed using µCT and nano-CT techniques. Cartilage matrix alterations were evaluated by scoring of Safranin O-stained sections of knee joints according to OARSI guidelines and by stiffness analysis using atomic force microscopy (AFM). Human chondrocytes obtained from OA patients after joint replacement and stimulated with SP or CGRP in 2D- and 3D-cell culture systems. Subsequently, proliferation, apoptosis, senescence, adhesion ability, GAG concentration, gene expression of marker genes and activation of signaling pathways was analysed. SP-deficient mice revealed a cartilage phenotype which might contribute to the considerable cartilage alterations early after induction of murine OA, ultimately leading to subchondral bone sclerosis at the early stage. In general, loss of sensory neuropeptides induced subchondral bone sclerosis in conjunction with advanced aging and not with OA. In addition, we conclude for both neurotransmitters dose-dependent effects on OA-chondrocyte metabolism and signalling via ERK and cAMP pathways. Underlying mechanisms remain elusive but changes in cartilage and bone cell composition might contribute to OA bone and cartilage phenotype which will be discussed in the presentation.

The human amniotic membrane for regenerative medicine - A critical overview

S. Wolbank¹,²

Presenting Author: Susanne Wolbank, susanne.wolbank@trauma.lbg.ac.at

¹Ludwig Boltzmann Institute for Experimental and Clinical Traumatology in the AUVA trauma research center, Vienna, Austria ²Austrian Cluster for Tissue Regeneration, Austria

Human amniotic membrane (hAM), one of the perinatal tissues arising as a waste material during birth, is well established as therapeutic biomaterial in the clinics. The clinical application is mostly concentrated within ophthalmology and wound care, both of which use devitalized/denuded hAM as barrier in homologous use, as classified by the regulatory authorities. Novel applications in regenerative medicine are currently emerging including stroke, lung damage, liver disease, chronic ulcers or myocardial infarction. On the other hand, a variety of novel hAM formulations have been developed that depend on processing such as drying, lyophilizing, homogenization, or the use of isolated amniotic cells. It is hence crucial to identify the modes of action that justify application for treatment of a specific condition, and in consequence to identify the most suitable formulation, especially since this will reflect on the regulatory classification of the product. Within this presentation different examples for applying hAM derivatives in the field of regenerative medicine will be discussed, comparing the applied formulations, the outcomes and in consequence potential modes of action. One focus will be the potential of hAM and the cells thereof for musculoskeletal regeneration, the second one will be anti-fibrotic applications of hAM derivatives. We and others have previously demonstrated that hAM is a promising gliding and anti-fibrotic material, preventing adhesions in the peripheral nerve, in hernia repair and a model of liver fibrosis. Another crucial point to be discussed is the heterogeneity of natural biomatrices. In hAM we have identified regional differences on various functional levels, including metabolic status, differentiation potential, secretion of cytokines, growth factors, vesicles and lipid components, which led us to conclude that depending on the application the origin of the tissue should be considered.
Systemically administered, yet target-specific therapeutic recombinant proteins for regenerative medicine

T.A.H. Järvinen
Presenting Author: Tero A.H. Järvinen, blteja@uta.fi
Faculty of Medicine and Life Sciences, University of Tampere and Department of Orthopedics and Traumatology, Tampere University Hospital, Tampere, Finland

Growth factors, chemokines, and cytokines responsible for tissue regeneration have been identified. Their therapeutic usage in humans is almost non-existent because of the difficulty in maintaining their bioactivity in the protease-rich milieu of injured tissues. Safety concerns related to unwanted accumulation of potent growth factors in healthy organs have ruled out their use as systemic administration. Systemic, yet target-specific delivery of therapeutic recombinant proteins could be the solution for their translation to the clinical medicine. Angiogenic vasculature forming in the regenerating tissues after injury/surgery provides an opportunity for doing that. Angiogenic blood vessels have unique molecular structures specifically expressed by them, essentially forming a “zip/postal code” for injured tissue. This unique vascular zip code specific for injury/surgery can be utilized as a molecular target for target-specific delivery of systemically administered therapeutics to tissue injuries by ligands (peptides or antibodies identified by in vivo phage display) binding to this specific structure. Molecules with therapeutic potential together with targeting device can be expressed as a part of multi-functional recombinant protein. The desired outcomes of the targeted delivery of therapeutic recombinant proteins are increased drug concentrations in the target and lowered accumulation of the therapeutic payload in the healthy organs. The targeted delivery of systemically administered recombinant proteins to the injured tissue is hopefully rapidly advancing to clinical trials to provide new therapeutics to regenerative medicine.
Two decades of commercializing nanomedicine to aid in human health: Real patient success stories
T.J. Webster
Presenting Author: Thomas J. Webster, th.webster@neu.edu / websterthomas02@gmail.com
Chemical Engineering, Northeastern University, Boston, MA, USA

There is an acute shortage of organs due to disease, trauma, congenital defects, and most importantly, age related maladies. The synthetic materials used in tissue engineering applications today are typically composed of millimeter or micron sized particles and/or fiber dimensions with nanometer smooth features. Although human cells are on the micron scale, their individual components, e.g. proteins, are composed of nanometer features. By modifying only the nanofeatures on material surfaces without changing surface chemistry, it is possible to increase tissue growth of any human tissue by controlling the endogenous adsorption of adhesive proteins onto the material surface. In addition, our group has shown that these same nanofeatures and nano-modifications can reduce bacterial growth without using antibiotics, which may further accelerate the growth of antibiotic resistant microbes. Inflammation can also be decreased through the use of nanomaterials. Finally, nanomedicine has been shown to stimulate the growth and differentiation of stem cells, which may someday be used to treat incurable disorders, such as neural damage. This strategy also accelerates US FDA approval and commercialization efforts since new chemistries are not proposed, rather chemistries already approved by the US FDA with altered nanoscale features. This invited talk will highlight some of the advancements and emphasize current nanomaterials approved by the FDA for human implantation. Most importantly, it will highlight real patient success stories from patients who have received nanomedicine products created in my lab.
Exercise enhances the treatment of volumetric muscle loss by stem cell transplantation
T.A. Rando1,2
Presenting Author: Thomas A. Rando, rando@stanford.edu
1Center for Tissue Regeneration, Repair, and Restoration, Veterans Affairs Health Care System, Palo Alto, California, USA 2Department of Neurology and Neurological Sciences, Stanford University School of Medicine, Stanford, California, USA

Stem cell mediated regeneration of injured or diseased tissue holds great promise as a means to restore tissue structure and function. Our research focuses on the use of muscle stem cells (MuSCs) for the treatment of muscle injuries, particularly those characterized as volumetric muscle loss (VML), using a mouse model of VML. Toward this end, we have studied the characteristics of MuSCs as well as other muscle resident mononucleated cells isolated by fluorescence activated cell sorting (FACS) from mice and from humans to understand the properties that maintain or enhance their potency following transplantation to restore normal structure and function to diseased or injured muscle. Our studies of treatment of VML have focused on the use of MuSCs engrafted onto decellularized muscle tissue employed as a scaffold for the transplantation of cells, and how best to enhance the regenerative potential of the MuSCs transplanted within those scaffolds. Whereas we have found negligible benefit of transplanting the scaffold alone, we have found marked improvement in the structure and functional restoration of injured muscle when scaffolds are seeded with MuSCs. Interestingly, we have found that those improvements are enhanced when MuSCs are transplanted along with other muscle resident cells, particularly cells of the endothelial lineage. More recently, we have focused on the benefits of exercise, in this case voluntary wheel running or forced treadmill running, on the efficacy of muscle regeneration after acute injury and on the efficacy of MuSC therapy for VML. Our studies show a marked enhancement of tissue restoration when mice engage in physical activity (voluntary wheel running) after cell transplantation for VML injuries. In particular, we observe an improvement in both vascularization and innervation of the newly formed muscle fibers. There is an increase in capillary density and an increase in the rate of formation of de novo, mature neuromuscular junctions in the muscles of mice that have engaged in physical exercise compared with those that have not been provided with a running wheel. Our long-term goals are to optimize multiple aspects of the process, ranging from the cells to the scaffolds to the physical activity regimen, to generate a scalable process that will lead to effective stem cell-mediated treatments of VML in humans.

ACKNOWLEDGEMENTS: Financial support was received from the Department of Veterans Affairs, USA (I01RX001222, I01BX002324), and the National Institutes of Health, USA (AG036695, AG047820).
From academia to industry: A translational research approach for soft tissue regeneration
T. Steinberg

Presenting Author: Thorsten Steinberg, thorsten.steinberg@uniklinik-freiburg.de
1Division of Oral Biotechnology, Center for Dental Medicine, University Medical Center Freiburg, Freiburg, Germany

Translational clinical research is an issue everybody is talking about. But the definition in the scientific community is somehow inconclusive, because the translational aspect in clinical research is not unidirectional, but rather means taking into account both point of views: the translation of knowledge from bench-to-bedside and from bed/chair-side to bench as well. Hence, we started a translational research approach for soft tissue regeneration in the oral cavity and here especially for large and full-thickness wound situations, because there is still no satisfying treatment solution on the market. Coming from this dual strategy, we developed a new wound healing medical device by implementing own basic research data and experiences from clinicians, which are facing the clinical need for specific wound situation day by day. The result was a biohybrid membrane, consisting out of two different polymers, gelatin and polycaprolactone, which mediate by an innovative production procedure, the electrospinning technology, and the hierarchic nano-fiber configuration, outstanding biomechanical, regenerative and handling characteristics. The key feature of the membrane is a nano-fiber gradient with increasing fiber diameters reaching from 100nm-800nm which mimics a soft tissue specific biomechanical nano-environment, enabling cells to migrate on those fibers, like a trafficking system, from the wound margins into the membrane [1-3]. To prepare this new developed wound healing device for commercialization, we performed extensive preclinical investigations to proof the safety and efficacy, firstly in vitro, by using human and tissue specific 3D cell cultures and in a further step with a pilot animal study in a mini pig model. Finally, we were able to perform a few individual health trails in patients suffering progressed oral carcinogenesis. All these promising and conclusive data were collected to bring this innovative project on a higher level that the medical device industry got interested to bring this product on the market. But the reality at Universities is that it is very hard or nearly impossible to transfer such a project from academia to the industry, because of the missing clinical data and the high risk from the viewpoint of the industry to fail. For this low readiness to assume a risk, we failed to find a strategic investor in Europe and the US for almost 6 years and finally found a very committed group of investors in China, who were willing to spend the risk money to found a new “medtec” company with the respective production infrastructure and support us on the way to get the regulatory approval for our innovative biohybrid membrane for soft tissue regeneration in China.

Considerations for manufacture of MSCs for clinical development

T. O’Brien
Presenting Author: Timothy O’Brien Timothy.Obrien@nuigalway.ie
REMEDI and CURAM, NUI Galway, Ireland

MSCs are currently being investigated for use in a wide range of clinical disorders. The therapeutic potential is related to their direct differentiation potential, the secretome capable of paracrine effects and the recently described immune reprogramming associated with their use. While a large number of clinical trials are underway worldwide there is wide variation in the methods of cell manufacture. This will make interpretation of trial outcome challenging and comparison between the outcomes of different trials problematic. A number of questions arise when an MSC product is under development including: cell source – bone marrow, adipose tissue, umbilical cord; the use of sorted versus bulk manufactured cells; allogeneic versus autologous; if allogeneic pooled versus individual donor; cell passage and population doubling; choice of bioreactor; conditioned versus unconditioned cells; and choice of xeno free media. Additional challenges reside around potency assays, mechanism of action, repeat dosing and the effect of disease on potential outcomes. A single product for development would have advantages and an off the shelf, allogeneic product cultured in a bioreactor under xeno free conditions would be ideal. These issues will be discussed in the context of developing an MSC therapeutic for the treatment of diabetic complications.
Glycosaminoglycan-based hydrogels for musculoskeletal regeneration
U. Freudenberg
Presenting Author: Uwe Freudenberg; freudenberg@ipfdd.de

Glycosaminoglycans (GAGs) govern important functional characteristics of the extracellular matrix in living tissues. Incorporation of GAGs into biomaterials opens up new routes for the presentation of signaling molecules, providing control over development, homeostasis, inflammation, and tumor formation and progression. Recent approaches to GAG-based materials are reported, highlighting the formation of modular, tunable biohybrid hydrogels, including both theory-driven design concepts and advanced processing technologies. Special emphasis is put on the independent tuning of molecular and physical cues within the GAG-based materials in order to control cell-fate decisions of embedded cells. Based on multi-armed poly(ethylene glycol), heparin, and selectively desulfated derivatives thereof we have developed a modular platform of cell-instructive hydrogels for various applications in the field of musculoskeletal regeneration. Angiogenesis promoting materials have been used for promotion of cardiac regeneration by sustained release of SDF-1a. Moreover, matrixmetalloprotease responsive starPEG-heparin hydrogels provided well-adjusted biomolecular and physical cues in order to guide MSC- and chondrocyte-based cartilage regeneration in vitro and in vivo. Finally, zonal hydrogel constructs allowed in vivo growth of bizonal cartilage with a stable calcified cartilage layer. As a perspective, multiphasic GAG-based hydrogel materials fabricated using microfluidic and additive manufacturing techniques shall allow for a fare-going control of cellular-co-cultures and finally may pave the way for innovative regenerative approaches in the musculoskeletal field and beyond.
Direct reprogramming of human fibroblasts as a novel tool in cardiac tissue engineering
V. Chiono 1
Presenting Author: Valeria Chiono, valeria.chiono@polito.it
1Department of Mechanical and Aerospace Engineering, Politecnico di Torino, Turin, Italy

Heart failure following myocardial infarction is the current leading cause of mortality in the industrialized world. Currently, the only clinical therapy addressing the irreversible loss of cardiomyocytes is heart transplantation. On the other hand, many tissue engineering approaches and cell therapies are under investigation to regenerate myocardial tissue. However, such approaches are limited by the poor grafting and survival ability of implanted cells and by the limited endogenous regenerative potential of human adult heart. Since 2010, a new promising strategy has emerged based on direct reprogramming of CFs into induced cardiomyocytes (iCMs) using transcriptional factors and/or microRNAs (miRNAs) (miR-combo) [1-4]. Early studies have demonstrated the in vitro and in vivo direct conversion of mouse CFs into iCMs and the in vitro direct reprogramming of human CFs [1-4]. However, before prospecting a translation of the approach into the clinics, direct reprogramming efficiency and iCM maturation level should be greatly improved. Particularly, the role of 3D scaffolds/hydrogels in direct cardiac reprogramming needs to be further investigated [3-4]. In this work, the miR-combo mediated direct reprogramming of human cardiac fibroblasts was studied for the first time, by culturing cells in 2D tissue culture plates and in 3D microenvironments consisting of fibrin-based hydrogels. Untransfected cardiac fibroblasts expressed cardiac genes, hence they are “primed” for direct reprogramming respect to other types of fibroblasts. In 2D cultures, after 3 days from transfection, miR-combo treatment increased cardiac gene expression while decreased vimentin gene expression respect to NegmiR control and untrasfected cells. On the other hand, cells cultured in 3D fibrin-based hydrogels as NegmiR control and untransfected cells showed enhanced cardiac gene expression than their 2D counterparts. However, miRcombo transfection did not enhance cardiac gene expression in cells cultured in 3D hydrogels respect to controls after 3 days. At higher times (7 and 15 days), CFs cultured in 3D hydrogels showed a strongly enhanced expression of cardiac genes such as cardiac troponin I and alpha myosin heavy chain 6. Immunocytochemistry data confirmed PCR analysis results. Hence, a 3D biomimetic environment was found to play a key role in enhancing direct reprogramming of human CFs which cannot be simply explained by an enhancement of early cardiac genes. Based on that gene expression profile of reprogrammed cells in different 3D microenvironments is under investigation.

ACKNOWLEDGEMENTS: This project has received funding from the European Research Council (ERC) under the European Union’s Horizon 2020 research and innovation programme (grant agreement No 772168; BIORECAR project).

Harmonized coordination of the myriads of metabolic reactions within a cell as well as regulation of cell-cell interactions in the context of optimized tissue homeostasis and even safe programmed death requires a highly sophisticated and rich communication language. Replacement of injured tissues and organs and their re-engineering with a purpose of successful regeneration may represent an even more complex task with a larger variety of refined signals. There is a compelling need for a more profound understanding and characterization of the signaling landscape by identifying and deciphering the complex interactive signals/markers leading to the balanced regulation of pro- and anti-inflammatory responses, immune reactions, cell differentiation, proliferation and death engaged by the re-engineering and transplantation therapy using suitable cells, biomaterials (including nanomaterials), and/or endogenous and exogenous factors and signals required for translating the great technological promise to clinical success. Historically, much research attention has been focused on cytokines and growth factors. For more than seven decades, lipid mediators - oxygenated free polyunsaturated fatty acids (PUFA) of several major classes such as octadecanoids, eicosanoids, docosapentanoids and docosahexanoids - have been studied and identified as essential components of the overall signaling system [1]. Latest developments of soft-ionization mass-spectrometry combined with high resolution liquid chromatography (LC) brought to life new opportunities offered by Redox Lipidomics. In this talk, I will discuss how this new technological breakthrough has lead to the discovery of a vastly richer communication/signaling opportunities by oxygenated PUFA-phospholipids encompassing hundreds of thousands of possible words in the language composed of individual molecular species of peroxidized phospholipids, their oxidatively-truncated electrophilic derivatives and their adducts with nucleophilic protein targets. Among the unearthing accomplishments in this emerging field of research, are the unique signals of programmed cell death. Oxygenated forms of mitochondria-specific phospholipids, cardio-lipins (CLs), have been identified as intermediates required for the execution of apoptosis. These signals are enzymatically produced by complexes of CLs with an intermembrane space hemo-protein, cytochrome c (cyt c). New classes of regulators of apoptosis have been designed and successful tested in vitro and in vivo - mitochondria-targeted electron scavenging nitroxides conjugated with specific peptides and imidazole-substituted fatty acids. Selective and specific oxidation of PUFA-phosphatidylethanolamines (PE) catalyzed by complexes of 15-lipoxygenase with a scaffold protein, PE-binding protein 1 (PEBP1) has been found critical for the execution of ferroptotic death program occurring in the endoplasmic reticulum and its specific domains, mitochondria-associated membranes. Deciphering of new signals formed from PUFA-neutral lipids and PUFA-phospholipids are important for understanding of the immune response and signaling by extra-cellular vesicles emitted by cells during the transplantation and tissue remodeling.

Abundant extracellular vesicles (EVs) are produced in the bone matrix throughout life, in response to many stimuli (mechanical load, inflammation…). It is known since the seventies that these EVs play a role in the mineralization of skeletal tissue. EV-based cell-free therapy appears to be a promising strategy for the restoration of bone defects. This novel system based on Mesenchymal Stem Cells (MSC)-derived EVs/exosomes provides a new therapeutic option for bone tissue engineering and showed promising potential in joint repair that is mediated by their immunosuppressive as well as pro-regenerative activities. MSC-EVs exert immunomodulatory as well as pro-regenerative effects and mimic therapeutic effects of MSCs. MSC-EVs carrying certain proteins and nucleic acids that can support healing of injured tissues. Strategies for advancing MSC-EV-based therapies are already ongoing. All these data indicate that EV-mediated transfer of mRNAs, miRNAs, or proteins from MSC may be used to reprogram surrounding cells and to support tissue repair. But EV-based exchange of genetic information may be bi-directional. Our working hypothesis is based on the transfer of active molecules (miRNAs, proteins…) associated to EVs derived from the injured cells (e.g. the cells in bone that experienced mechanical stress), to MSCs or other bone cells in order to induce their differentiation or activation, which may then contribute to the bone repair. The role of EVs and their associated molecules in different cells in bones and neighboring tissues (cartilage, blood vessels…) will be discussed in the context of bone regeneration.

Rapid expansion of mesenchymal stem cells using media supplemented with human platelet lysate, suitable for cGMP expansion at large scale

V. Alonso-Camino¹

Presenting Author: Vanesa Alonso-Camino, alonso-camino.vanesa@millcreekls.com

¹Mill Creek Life Sciences, LLC, Rochester, Minnesota, USA

Mesenchymal Stem Cells (MSCs) are a promising candidate for tissue engineering and regenerative medicine applications due to their capacity of self-renewal and multilineage differentiation, ease of isolation and ability to grow in vitro. They are currently being used in hundreds of clinical trials and have been safely administered to thousands of patients with an expanding body of evidence of therapeutic efficacy. Mill Creek Life Sciences’ PLTMax®, derived from normal human donor platelets, arose as an alternative to FBS to be used as a supplement for in vitro expansion of human cells used in translational medicine [1]. It is the only media supplement to date demonstrating clinical cultures of MSCs with long term genetic fidelity [2], rapid expansion and potent clinical activity. PLTMax® is being used worldwide in over 30 clinical trials including Phase I, II and III [3]. The effective transfer into the clinic of allogenic cell therapies using MSCs will depend predominantly on the development of large scale and cost effective manufacturing platforms that allow production of functional cells at the scale required to meet clinical demand. Here we will present the development of an optimized protocol for the establishment of large scale expansion of MSCs using PLTMax® and PLTGold®, a second-generation human platelet lysate that does not require the addition of heparin to remain clot free, thus providing a fully xenogeneic free alternative supplement to grow cells that will be used in clinical applications.

Regulation of cell fate and differentiation by SOX transcription factors in skeletal development, homeostasis and disease

V. Lefebvre¹

Presenting Author: Véronique Lefebvre, lefebvre1@email.chop.edu

¹Translational Program in Pediatric Orthopaedics, Department of Surgery/Division of Orthopaedic Surgery, Children’s Hospital of Philadelphia, Philadelphia, USA

The development and adult homeostasis of our skeleton require proper specification and coordinated, fully functional activities of skeletal progenitor/stem cells and downstream cell types, namely growth plate chondrocytes, articular chondrocytes, synovial fibroblasts, and osteoblasts. The cellular and molecular mechanisms involved in the governance of these processes are extremely complex, as are the anatomical and functional properties of our skeleton and as are the many diseases that can affect our skeleton and seriously impact our lives at any age. Research conducted worldwide over the last decades has uncovered major regulatory players in these processes, such that it is now becoming possible to decode the molecular basis of various diseases and to rationally design preventive and therapeutic strategies for these diseases. Research in the Lefebvre laboratory has focused on transcriptional mechanisms that rank high in the hierarchical regulation of cell lineage determination and differentiation in the skeletal system. Several members of the SOX transcription factor family have been discovered to be pivotal. This talk will review milestones achieved in recent years and research directions being currently pursued. It will include an overview of the cellular and molecular activities of the master chondrogenic factor SOX9 in the early step of specification of progenitor/stem cells to the chondrocyte lineage as well as in the ultimate steps of adult articular chondrocyte homeostasis and fight against osteoarthritis. It will newly reveal a key partner of SOX9 in the chondrocyte lineage and will identify highly conserved motifs in the proteins that are critical for their transcriptional activation functions. The presentation will also highlight the critical importance of SOX4 and SOX11 in specifying skeletal progenitor/stem cells and in controlling timely differentiation of downstream lineages, such as osteoblasts. Finally, a discussion will be opened on the implication of these findings for translational and clinical applications, including tissue engineering strategies.

Development of enabling platform technology for bioprinting of functional and vascularized endocrine human organ constructs
V.A. Mironov
Presenting Author: Vladimir A. Mironov, vladimir.mironov54@gmail.com
Laboratory of Biotechnology Research of 3D Bioprinting Solutions, Moscow, Russia & Regenerative Medicine Institute of Sechenov Medical University, Moscow, Russia

Organ printing could be defined as an automated robotic 3D biofabrication of functional human tissue and organs from living cells and bioprintable biomaterials according to digital model. Here we report first time about the development of novel platform technology for bioprinting of functional and vascularized human endocrine organs using tissue spheroid as building blocks. Bioprinting platform technology includes development of viscous porcine collagen (VisCol) as a bioprintable hydrogel and bioprinter FABION capable to print tissue and organ constructs using viscous collagen scaffold and tissue spheroids. Organo-specific tissue spheroids have been proposed to use for bioprinting of organ parenchyme and endothelial tissue spheroids for bioprinting organ vasculature. Commercially available non-adhesive multiwells (Corning, USA) have been used for biofabrication of tissue spheroids. Viscous porcine collagen have been used for bioprinting porous scaffold with pores suitable for placing tissue spheroids. Tissue spheroids have been precisely automatically placed one spheroid a time into bioprinted scaffold using microfluidic device incorporated into multifunctional bioprinter FABION. The bioprinted tissue and organ constructs have been transplanted on chick chorio-allantoic membrane for estimation their post-printed vascularization, viability and functionality. It have been shown using human ovarian tissue spheroids that bioprinting of functional and vascularized human ovarian tissue is technologically feasible. Thus, our data clearly illustrate a potential of using proposed platform technology for 3D bioprinting of several endocrine functional and vascularized human organs such as thyroid gland, parathyroid gland, ovary, testis, adrenal grand, endocrine part of pancreas and thymus.
Sheep and goat as model animals for cartilage repair in biomedical research

W. Brehm¹²

Presenting Author: Walter Brehm, brehm@vetmed.uni-leipzig.de

²Saxonian Incubator for Clinical Translation (SIKT), University of Leipzig, Leipzig, Germany

Sheep and Goat have been widely used for translational research in various fields with an emphasis on orthopedic research. Bone regeneration, tendon healing, vertebral surgery particularly cartilage repair are important topics using these species. Recently, the fact that the Sheep usually give birth to twins was used to study the healing of osteochondral defects in ovine fetuses. While the size and the biomechanical features of the Sheep and the Goat together with their availability, cost of purchase and cost of keeping are frequently cited arguments for the choice of both species for experimental approaches, it is of paramount importance to be aware of the specific behavioural, physiologic and immunologic characteristics, which have to be respected when planning and performing studies in these species. To name a few spots, the behavior of Sheep and Goat after experimental surgery is fundamentally different from Human, in that these animals will fully load their locomotor system very shortly after anaesthesia. Considering this is of fundamental importance upon planning as study focused on cartilage repair. Sheep and Goat both have a strong immune system, which needs to be respected when planning the application of potentially immunogenic materials. As an example, the application of bovine fibrin glue has led to massive invasion of immune cells in a osteochondral defect model in the Goat. Experimental design has to respect the anatomy, biomechanics, physiology and immunology of the model species to avoid false negative results of potentially beneficial treatment strategies, and even more to reduce the unnecessary use and suffering of animals. We will therefore present an overview of ovine and caprine cartilage defect models pointing out pros and cons, how to improve the outcome and how to avoid pitfalls.

ACKNOWLEDGEMENTS: Thanks to all the colleagues with whom I had the pleasure to work.

Regeneration of functional human lung by distal airway stem cells: From benchside to bedside
Wei Zuo¹,²
Presenting Author: Wei Zuo, zuow@tongji.edu.cn
¹Shanghai Pulmonary Hospital, School of Medicine, Tongji University, Shanghai ²Kiangnan Stem Cell Institute, Zhejiang, China

Irreversible destruction of bronchi and alveoli can lead to multiple incurable lung diseases. Identifying lung stem/progenitor cells with regenerative capacity and utilizing them to reconstruct functional tissue is one of the biggest hopes to cure such diseases. Previously we demonstrated lung regeneration in mice following H1N1 influenza virus infection, and linked distal airway stem cells (DASCs) expressing Trp63 (p63) and keratin 5, to this process. Pre-existing, intrinsically committed DASC(p63/Krt5) undergo a proliferative expansion in response to lung damage, and assemble into nascent alveoli at sites of interstitial lung inflammation. Selective ablation of DASC in vivo prevents this regeneration, leading to pre-fibrotic lesions and deficient oxygen exchange. Recently we showed that a rare population of SOX9+ DASCs located at airway epithelium rugae can regenerate adult human lung. SOX9+ DASCs can be readily isolated by bronchoscopic brushing and indefinitely expanded in feeder-free condition. Expanded SOX9+ DASCs can differentiate into alveolar cells in a monolayer in vitro culture system. Such cells can also give rise to alveolar and bronchiolar epithelium after being transplanted into injured mouse lung, with air-blood exchange system reconstructed and recipient’s lung function improved. Moreover, we conducted the first autologous DASC transplantation clinical trials in patients with bronchiectasis, COPD and IPF, respectively. Lung tissue repair and pulmonary function enhancement was observed in patients 3~12 months after cell transplantation. Altogether our current work indicated that functional adult human lung structure can be reconstituted by orthotopic transplantation of tissue-specific stem/progenitor cells, which could be translated into a mature regenerative therapeutic strategy in near future.

Injectable scaffolds for wound healing
W.X. Wang
Presenting Author: Wenxin Wang, wenxin.wang@ucd.ie
Skin Research and Wound Healing Group, Charles Institute of Dermatology, School of Medicine, University College Dublin (UCD), Dublin, Ireland

Adjusting biomaterial degradation profile to match tissue regeneration is a challenging issue. Poly(β-amino esters) (PBAEs) and their networks have attracted great attention as biodegradable polymers in the field of tissue scaffolds and gene delivery. However, the mechanical properties and biological effects were limited due to the linear structure and poor solubility. Therefore, a series of novel hyperbranched PBAEs (HP-PBAEs) with three-dimensional architecture have been developed as the improved construct for generation of biocompatible and injectable hydrogel. The polymers displayed fast gelation with thiolated hyaluronic acid (HA-SH) via “click” thiol-ene reaction. HP- PBAE/HA-SH hydrogels showed tuneable degradation profiles both in vitro and in vivo by using diamines with different alkyl chain lengths and poly(ethylene glycol) diacrylates with varied PEG spacers. The hydrogels with optimized degradation profiles encapsulating ADSCs were used as injectable hydrogels to treat two different types of humanized excisional wounds - acute wounds with faster healing rate and diabetic wounds with slower healing and neo-tissue formation. The fast-degrading hydrogel had the accelerated wound closure in acute wounds, while the slow-degrading hydrogel showed better wound healing for diabetic wounds. The results demonstrate that the new HP-PBAE-based hydrogels in combination with ADSCs can be used as a well-controlled biodegradable skin substitute, which demonstrates a promising approach in the treatment of various types of skin wounds.
Biomaterials and biofabrication methods for musculoskeletal tissue engineering
W. Swieszkowski
Presenting Author: W. Swieszkowski, wojciech.swieszkowski@pw.edu.pl
Faculty of Materials Science and Engineering, Warsaw University of Technology, Warsaw, Poland

This study shows a biofabrication technology which relies on the simultaneous deposition of cells and biomaterials in a layer-by-layer fashion, to form 3D well-organized heterogeneous structures that can mirror relevant complex biological architectures both physiologically and morphologically. Our 3D biofabrication approach is based on a microfluidic system coupled to a co-axial needle extruder for high-resolution computer-controlled 3D deposition of hydrogel fibers laden with different cells. By formulating tailored hydrogel based bioink and precisely controlling the 3D spatial organization of the extruded hydrogel fibers, the novel 3D bioprinting method has been tested for the fabrication of advanced engineered constructs for the regeneration of musculoskeletal tissues [1,2]. Depending on application, the biomimetic hydrogels were composed of modified biopolymers like gelatin, alginate, hyaluronic acid, or PEG-fibrinogen. The gels were laden with different types of cells including bone marrow-derived human mesenchymal stem cells, muscle precursor cells or chondrocytes. The obtained with high resolution (~ 100 μm), a fiber-based 3D printed living constructs mimic organized musculoskeletal tissues like bone, cartilage, tendon or muscle.

Extracellular vesicles in blood and lymphatic vasculature

W. Holnthoner

Presenting Author: Wolfgang Holnthoner, wolfgang.holnthoner@trauma.lbg.ac.at
Ludwig-Boltzmann-Institute for Experimental and Clinical Traumatology, Austrian Cluster for Tissue Regeneration, Vienna, Austria

Extracellular vesicles (EVs) include exosomes, microparticles, and apoptotic bodies and are phospholipid bilayer-enclosed vesicles that have once been considered as cell debris lacking biological functions. Recently, however, these structures gained tremendous interest, since they are believed to be implicated in a variety of pathological settings. EVs, which are secreted by endothelial cells, have been found to play diverse roles in disease by promoting cardiovascular diseases, but also survival of endothelial cells. One of the main challenges in this field is the isolation and characterization of EVs. Different methods have been developed, yet, standardization of the protocols is still lacking behind. This calls for clinically approved, standardized, and efficient isolation and characterization protocols to harvest and purify endothelial extracellular vesicles. However, such methods and techniques to fulfill stringent requirements for clinical trials have yet to be developed or are not harmonized internationally. The focus of our lab lies in the enrichment and characterization of endothelial EVs. We analyze the obtained fractions by thromboelastometry, nanoparticle tracking analysis and flow cytometry. Our aim is a better understanding of the role of endothelial cell-derived EVs in coagulation, but also their function in cell-cell communication between endothelial and their surrounding stromal cells in tissue engineered vasculature.

Molecular and functional analysis of MSC-derived extracellular vesicles in the context of osteoarthritis

X.-N. Wang
Presenting Author: Xiao-nong Wang, x.n.wang@newcastle.ac.uk
1Institute of Cellular Medicine, Newcastle University, UK

INTRODUCTION: MSC secreted extracellular vesicles (MSC-EVs) showed chondroprotection and osteoarthritis attenuation in animal models. Our previous work observed a distinctive miRNA expression profile in MSC-EVs compared to their parental MSCs. We further investigated the chondrogenesis miRNAs in MSC-EVs and their impact on human osteoarthritic chondrocytes.

METHODS: MSC-EVs were isolated from MSC-conditioned media by differential ultracentrifugation. MSC-EV enclosed chondrogenesis miRNAs were assessed by qRT-PCR. Human articular chondrocytes (HACs) were generated from the articular cartilage from patients with osteoarthritis. Following co-culture, the effect of MSC-EVs on HAC migration was examined by scratch assay and chemotaxis assay.

RESULTS & DISCUSSION: MSC-EVs expressed EV signature markers CD63, CD9, CD81, Alix and Flotillin-1 with characteristic particle size range and cup-shaped morphology. MSC-EVs contained well-recognised chondrogenesis microRNAs, with miR-140-5p, miR-142-3p, miR-145-5p, miR-630, miR-29b-3p expression significantly higher and miR-125b expression lower than their parental MSCs. HACs were capable of acquiring MSC-EVs (Figure 1). The HACs exposed to MSC-EVs showed a faster wound closure and high migration capacity compared to those not exposed to MSC-EVs (Figure 1).

CONCLUSIONS: MSC-EVs encapsulate well-recognised chondrogenesis microRNAs. MSC-EVs have functional impact on human osteoarthritic articular chondrocytes. These findings may have implications in developing cell-free therapy for degenerative diseases such as osteoarthritis.

Figure 1: Confocal microscopy images of HACs uptake MSC-EVs. Red=PKH26 labelled MSC-EVs, green=WGA-488 stained cell membrane, blue=DAPI stained cell nucleus. The scale bars indicate 5um. Effect of MSC-EV on HACs wound closure (left, n=12) and transwell migration (right, n=6). Error bars indicate mean +/- SEM.

Bone tissue engineering in vitro and in vivo using 3D printed scaffolds
X.B. Yang
Presenting Author: Xue Bin Yang, x.b.yang@leeds.ac.uk
Biomaterials & Tissue Engineering Group, Division of Oral Biology, School of Dentistry, University of Leeds, UK

The ability to generate functional bone tissue is still a major challenge for clinical translation. Although many different types of biomimetic scaffolds are available, however to date, many researchers are still working on the development of ‘functional’ biomaterials for bone tissue engineering applications. Since bone formation is a dynamic process, it may require different properties of the scaffolds during the entire period of the bone regeneration. This talk will start with an overview of the natural procedure of bone development, fracture healing, as well as bone remodeling during lifetime, which may provide evidence-based guide for the design and manufacture of novel biomaterial scaffolds for functional bone tissue regeneration. It has been general accepted that an ideal scaffold for bone formation should be biocompatible, biodegradable, osteoinductive, osteoconductive, cost effective and supporting angiogenesis, extracellular matrix production and mineralisation. This talk will demonstrate the use of different commonly available 3D scaffolds (such as PLA/PLGA, BioGlass, Glass ceramics, and so on) for bone tissue engineering both in vitro and in vivo, and discuss the advantages and limitations of different scaffolds. Over the last a few years, 3D bioprinting have become one of the most advanced technologies for biomaterials design and fabrications. The 3D printed poly-lactic acid (PLA) scaffolds has great potential to tailor different geometrical designs for improved cellular attachment and growth. In collaboration with Dr Liu at University College London, we have investigated the effect of fibre angle in 3D printed PLA scaffolds on human dental pulp stem cells (hDPSC) attachment, growth and osteogenic differentiation, both in vitro and in vivo. PLA scaffolds containing fibres angled at either 45° or 90° were prepared via 3D printing (UCL). hDPSCs were pre-labeled with Cell Tracker Green prior to be seeded on the 3D printed scaffolds for 4 hours. Fluorescence microscopic images showed that 45° angled PLA scaffolds significantly enhanced the cell attachment compared to that on the 90° angled PLA group (p<0.0001). After 3 weeks of osteogenic culture in vitro, SEM confirmed that almost all macro-pores were fully covered with cell sheets in the 45° angled PLA group. In contrast, only a limited amount of cellular bridging was present in the 90° angled PLA group. The majority of cells on the 3D printed scaffolds in both groups are viable with only a few dead cells at weeks 4. After 5 weeks, histology showed marked cellular growth and new collagen matrix formation, with positive immunohistochemical staining to bone specific markers in both groups. In a separated study, a novel histone deacetylases inhibitor (HDACi) - MI192 were used to pre-treat human bone marrow stromal cells (hBMSCs) for two days prior to be cultured as pellets and assembled in a 3D printed PEGT/PBT scaffold to form the Micro-Tissue (In collaboration with Dr Woodfield in Otago University). Then the Micro-Tissues were cultured in osteogenic medium for 6 weeks. Results showed that MI192 pre-treatment extensively enhanced hBMSCs ALP, OCN and Coll1α protein expression and extracellular matrix mineralisation within the in Micro-Tissues, which indicate the potential of using MI192 pre-treated cells and 3D printed scaffolds for bone tissue regeneration.

Regenerative therapy is a medical treatment based on the natural-healing potential of body itself. To realize the regenerative therapy, it is necessary to enhance the cell ability of proliferation and differentiation which contributes to the healing potential. To this end, several biomaterial technologies have been investigated to give cells a local environment for their ability enhancement. If a cell scaffold or a key bio-signalling molecule is supplied to the right place at the right time or concentration by the release technology of biomaterials, the body system initiates to physiologically function, resulting in the natural induction of cell-based tissue regeneration. With the recent scientific development of stem cell biology, various molecules to enhance in vivo cell recruitment have been available for cell-based regenerative therapy. For example, the controlled release of a cell recruitment molecule can enhance the in vivo recruitment of stem cells, followed by the local functional activation of cells recruited by another drug released, resulting in a promoted cell-based tissue regeneration. On the other hand, inflammation is one of the essential host responses to pathologically modify the process of tissue regeneration. Without inflammation, no tissue regeneration takes place. The inflammation process was modified through the local release technology of an anti-inflammatory drug. The positive regulation of inflammation further enhanced the therapeutic efficacy of tissue regeneration induced by the release technology. Tissue regeneration based on the in vivo cell recruitment is a new and promising therapeutic strategy of regenerative medicine.
Development of dynamic culture systems to investigate the topographic influence on the limbal epithelial stem cells’ fate
Y. Yang
Presenting Author: Ying Yang, y.yang@keele.ac.uk
Institute for Science & Technology in Medicine, School of Medicine, Keele University, Stoke-on-Trent, UK

The limbus lying between cornea and conjunctiva is an important tissue for the cornea maintenance and repair. The limbal stem cells are found to reside at the basal of Palisades of Vogt (POV). Observing closely at POV, it is understood that limbal stem cells share the common anatomic feature of compartmental locations as other adult epithelial stem cells, such as in skin [1], intestine or airway tract (alveoli). However, the role and types of insoluble molecules, extracellular matrix (ECM) composition and especially topographic features of ECM acting as stem cell niche have not been fully elicited. In this project, two different bioreactors, including suction bioreactor and compression bioreactor, were designed to mimic the limbal stem cell niche of POV in limbus. The suction bioreactor and compression bioreactor can change the cell culture substrate from flat to curved morphology after cells attaching on the substrates. We hypothesized that the curved substrates would change the aggregation and migration state of the limbal stem cells, and the change would be curvature size dependent. Limbal stem cells were extracted from porcine limbus tissues and identified by their unique surface marker, p63 antibody. After 48 hours culture of the corneal limbal stem cells on the bioreactors, several p63 positive cells were aggregated heterogeneously depending on the curvature of the substrate. Furthermore, higher density of p63 positive cells were maintained and aggregated more in stem cell culture media. Thus, the two new bioreactors offer a unique tool to mimic the limbal structure enabling deeper understanding of limbus function for better corneal disease treatment.

INTRODUCTION: There is a growing interest in the development of biomaterials involving the immobilization of growth factors, which would allow these artificial materials to regulate specific cellular functions, including the gene expression processes associated with cell growth and differentiation. To design such proteins as a strategy for the surface modification of metals and ceramics, biomimetic approaches inspired by underwater adhesive proteins have been employed with biological materials. One of the proteins is the salivary stathelin protein which is a multifunctional molecule that possesses a high affinity for calcium phosphate minerals such as hydroxyapatite (HA), maintains the appropriate mineral solution dynamics of enamel, promotes selective initial bacterial colonization, and functions as a boundary lubricant on the enamel surface.1 Another is mussel foot protein which is involved in a sticky pad at the end of threads which stick firmly to rock, or any other hard surface. It is known that the active sites for the adhesion of both proteins consist of post-translationally modified amino acids such as phosphoserine and 3,4-dihydroxyalanine (DOPA). Here two kinds of growth factor epidermal growth factor (EGF) and insulin-like growth factor (IGF) were modified with the motif.

METHODS: To prepare phosphoserine-incorporated EGF, we employed the solid phase synthesis method. The minimum portion of bio-active EGF was conjugated with the short peptide with the binding sequence in statherin. Tyrosinase treatment was employed for incorporation of DOPA into IGF by converting the tyrosine residues to DOPA. In the procedure, a tyrosine-lysine-tyrosine-lysine-tyrosine sequence was added to the C-terminal of IGF using conventional genetic recombinant technology. Subsequently, the tyrosine residues in the product were converted to DOPA residues by tyrosinase.

RESULTS & DISCUSSION: The EGF derivative bound to HA and titanium (Ti), whereas unmodified EGF did not. In addition, smaller amounts of bound EGF had higher effects than soluble EGF. As a conclusion, the bound EGF has higher activity than the soluble form because of its immobilization. The binding affinity of IGF was also significantly higher than that of IGF. Furthermore, the bound IGF did not dissociate even after it had been washed with phosphate buffered saline. The cell growth assay using NIH 3T3 cells also showed that the bound IGF produced a significant enhancement of cell growth, compared with soluble IGF. The relative activities of immobilized or bound growth factor have also been observed for other growth factors. The activity is attributed to high local concentrations of immobilized growth factor, as well as the multivalency and inhibition of down regulation by the bound growth factor.

CONCLUSIONS: We have provided a summary of new adhesive growth factors prepared by site-specific incorporation of non-natural amino acids which play a key role in underwater adhesive proteins. In future, the combination of these approaches will provide new design tools for protein engineering and biomaterials.

Bioprinting has recently emerged as an enabling technology in tissue biofabrication at high fidelity. This talk will discuss our recent efforts on developing a series of advanced bioprinting strategies, including sacrificial bioprinting that allows generation of perfusable microchannels embedded in hydrogel microchannels, microfluidic and hollow fiber bioprinting that achieves production of standalone cannular tissues, and multi-material bioprinting based on both extrusion and stereolithographic modalities that enables creation of complex hierarchical tissue microstructures. Innovations in various cytocompatible and bioactive bioink formulations will also be presented. These platform bioprinting methods have been demonstrated to facilitate faithful fabrication of biomimetic tissues and their models spanning from the heart, liver, and musculoskeletal system to blood vessels and beyond, as well as their diseased forms, for applications in regenerative medicine and in accurate screening of therapeutic agents.

Smart biomaterials are increasingly used in tissue engineering and regenerative medicine. Based on smart biomaterials, three-dimensional scaffolds, cell sheets, theranostic systems, as well as numerous drug delivery systems had been developed. The key factors in the design and development of smart biomaterials and intelligent structures are molecular design and fabrication techniques. Moreover, in recent years, interest in the principles of the fabrication of smart biomaterials has grown particularly. Attention to various methods of fabrication is primarily due to the minimization of products. In addition, it is necessary to obtain hierarchically organized structures at various characteristic lengths from nm to cm. In this report, we consider the concept of design and fabrication of biomaterials on the example of thermoresponsive polymers with low critical solution temperature. Over the last couple of decades a number of innovative approaches to manufacturing thermoresponsive films for advanced cell culture applications have been developed and refined. Unlike traditional cell culture detachment methods, detachment from thermoresponsive substrates allows for the detachment of cells without the disruption of cell-to-cell junctions [1-3]. Therefore this approach can facilitate the harvesting of cell sheets, which can be applied for tissue engineering purposes. Thermoresponsive films have been successfully employed to host mammalian cells with a view to tissue reconstruction, such as corneal, endothelial and many others. In this report, we will analyze various methods for obtaining thermosensitive thin and ultrathin films. Among them: grafting, spin coating [1], photo crosslinking [2], physical sorption [3] and others. We will demonstrate, that method of preparation of the thermoresponsive materials seems to have a considerable influence on biocompatibility [1]. In conclusion, we consider the relatively new use of the thermosensitive materials for the fabrication of three-dimensional scaffolds. In particular, we give examples of the use of thermosensitive polymers for electrospinning and 3D printing.

Macrophages as important players in regeneration of osteochondral defects

Y.M. Bastiaansen-Jenniskens

Presenting Author: Yvonne M. Bastiaansen-Jenniskens, y.bastiaansen@erasmusmc.nl

Department of Orthopedics, Erasmus MC, University Medical Center Rotterdam, The Netherlands

Joint injuries may result in cartilage defects and inflammation of the joint. The immune response and inflammatory environment are known to directly influence the repair tissue produced. Macrophages are one of the cell types residing in synovium and intra-articular fat tissues and can acquire a spectrum of phenotypes with the pro-inflammatory or M1 macrophages and anti-inflammatory/repair or M2 macrophages on both ends of this spectrum. Stimuli from the environment can direct the macrophages to these different phenotypes. Cytokines and growth factors are the usual suspects here, but extracellular matrix, immune complexes, bacterial fragments, and implanted biomaterials can also alter the phenotype of macrophages. We have demonstrated that the secretome of synovium or infrapatellar fat pad tissue can influence the cartilage formation by bone marrow derived stromal cells (MSCs). When comparing the reaction of isolated tissue macrophages from osteoarthritic synovium or infrapatellar fat pad with the effect of peripheral blood monocytes that were differentiated to M1 and M2 macrophages in vitro, the effect of macrophages from osteoarthritic joint tissues was mostly comparable to the effect of M1 macrophages [1, 2]. We are investigating the ability to modulate the macrophage phenotype in the tissue, aiming to create an environment that fosters cartilage regeneration. First attempts are made in our lab to modulate macrophages residing in the synovium or infrapatellar fat pad using commonly used drugs. The results of these experiments are encouraging; Triamcinolone is capable of modulating macrophage phenotype in the tissue from pro-inflammatory to anti-inflammatory, whereas rapamycin has the opposite effect. Treatment of synovium and infrapatellar fat pad explants with triamcinolone reduced the negative effects of these tissues on MSC chondrogenesis in vitro. Taken together, targeting macrophages seems a good strategy when aiming for regenerative therapies and possibilities seem to exist to improve this regeneration via the macrophage.

INTRODUCTION: Currently, there is a lack of knowledge surrounding the relationship between naïve mesenchymal stem cells (MSCs) and the low oxygen, pro-inflammatory niche of the degenerate intervertebral disc (IVD). The objective of this study is to identify secreted factors from donor-matched adipose (ASC) and bone-marrow (MSCs) derived stem cells that may potentiate the survival and ingrowth of sensory nerve fibres present within degenerate discs and their regulation by oxygen tensions and inflammatory cytokines.

METHODS: Donor-matched ASCs and MSCs were stimulated with either IL-1β (10ng/ml) or TNFα (10ng/ml) for 48 hours in either 21% or 5% O₂. Quantitative real-time polymerase chain reaction analysis (qRT-PCR) was performed to assess expression of trophic factors involved in the survival of nerves (NGF, BDNF & NT3), blood vessels (VEGF, FGF-2, Ang-1 & Ang-2) as well as expression of pain associated neuropeptides (Substance P & CGRP) from ASCs and MSCs. Conditioned media was collected and secreted proteins were analysed using enzyme linked immunosorbent assays and multiplex human magnetic Luminex® assay.

RESULTS & DISCUSSION: Here, we report constitutive expression and secretion of neurotrophic and angiogenic factors from donor-matched ASCs and MSCs, demonstrating that hypoxic stimulation of ASCs triggers increased secretion of NGF, NT-3, Ang-1, Ang-2 FGF-2 and VEGF-A compared to MSCs. We demonstrate transcriptional and translational upregulation of NGF, Ang-1 and FGF-2 in response to cytokines in ASCs under 21% and 5% oxygen (Figure 1).

CONCLUSIONS: To the best of our knowledge this is the first report addressing the response of human donor-matched ASCs and MSCs to a hypoxic and inflammatory environment in terms of assessing their neurovascular profiles. This work demonstrates the importance of cell-selection for tissue specific regeneration to reduce ectopic sensory nerve growth and improve patient outcomes.

INTRODUCTION: The mechanical inputs form the surrounding microenvironment are interpreted by cells using mechanotransduction pathways. Fibers have been employed to mimic the extracellular matrix (ECM) to regulate cellular responses. [1]

METHODS: Fabrication of multi-layered 3D structured fibers with precise diameter, inter-fiber distance and angle, and specific surface topographies is demonstrated by using solvent assisted spinning (SAS). The fiber surface topography is altered by applying solvents with different solubility and volatility. The surface topography, hydrophobicity, crystallinity and stiffness of fibers are evaluated. To investigate the their mechanotransduction behavior, cells are stained for F-actin, vinculin, and two different mechanosensitive reporter proteins, Yes-associated protein (YAP) and myocardin related transcription factor A (MRTFA).

RESULTS & DISCUSSION: Depending on the solvent system, thermal or non-solvent induced phase separation results in microfibers with smooth, grooved, or porous fibers. Due to their hierarchical structures, the porous fibers are the most hydrophobic, followed by the grooved and smooth fibers, respectively. Increasing the polymer concentration or changing the nozzle size leads to a range of fiber diameters from ~2 to 10 µm. Interestingly, SAS fibers demonstrate higher degrees of crystallinity compared to polymer pellets, while AFM measurements suggest a stiffness in the MPa range without significant differences between the surface topographies. The average ratio of YAP fluorescence intensity (Fnucleus/Fcytoplasm) is ~ 1.91, whereas in case of smooth fibers, this ratio increases when cells are grown on porous (~ 2.91) or grooved (~ 3.37) fibers.

CONCLUSIONS: This report shows for the first time that, unlike for stiff 2D substrates (e.g. TCPS) where only stiffness matters, YAP shuttling can be influenced by the topography of substrates in case of 2.5D single microfibers. As cells undergo a forced apical/basal polarity on 2D substrates but wrap around the fibers in a more 3D manner, the internal stresses of the F-actin filaments will change, which may lead to alterations in the mechanotransduction pathways. As the composition, stiffness, and crystallinity of fibers are similar between the fibers with different surface topographies, cells seem to sense nanotopographies and spread accordingly, independent of the other parameters. SAS, therefore, provides a unique platform to study the interaction between cells and single ECM-like fibers in a precise and reproducible manner, which is of great importance for new material developments in the field of tissue engineering.

INTRODUCTION: Efficient initiation of differentiation of human pluripotent stem cells (hPSCs) is dependent on the responsiveness of stem cells to external induction cues, which is a prerequisite for deriving a homogeneous population of nephron progenitor cells (NPCs) and ureteric bud cells (UB). In this study, we improved protocols for driving efficient differentiation of hPSCs into NPCs and developed an extracellular matrix (ECM) based hydrogel for further improving the differentiation of NPCs into renal vesicles.

METHODS: We induced reversible arrest of hPSCs in G1 phase of cell cycle validated by the expression of Retinoblastoma protein-I(RB1). We compared the differentiation ability of synchronized and non-synchronized hPSCs into NPCs, and into renal vesicles. The NPCs were characterized by QPCR, immunocytochemistry, and flow cytometry. We further developed a sacrificial kidney ECM (K-ECM) based hydrogel and evaluated the morphology and architecture of the protein fibers comprising the hydrogel for long-term stability of these hydrogels in vitro.

RESULTS & DISCUSSION: RB1 expression was visualized to be homogenously over-expressed by ShPSC compared to UNShPCS. The efficiency of derivation of NPCs and UB in ShPSC was improved (93-99%) respectively, compared to UNShPCS (73%), which also translated to efficient renal vesicles output. The NPCs were characterized by the co-expression of SIX2, SALL1, CITED1, PAX2 and N-Cad. The UB were characterized by the co-expression of CXCR4 and CD117. K-ECM derived hydrogels not only supported the maintenance of NPCs, but also the formation of renal vesicles from NPCs upon induction with exogenous Activin-A and FGF-9, as characterized by flurochrome conjugated LTL.

CONCLUSIONS: Collectively, these data clearly illustrate the beneficial effect of cell synchronization and ECM driven efficient differentiation of hPSCs. This strategy holds the potential to provide a platform to get sufficient and homogenous number of NPCs and renal vesicles for kidney regeneration, drug screening and in vitro disease modeling of kidney disorders.

1Department of Chemical Engineering, Northeastern University, Boston, MA 02115, USA

INTRODUCTION: Health care system is facing significant concerns nowadays such as antimicrobial resistance and cancer. New approaches should be considered, and nanotechnology has been found as a powerful solution to them. Current synthetic methodologies for production of nanoparticles, based on physicochemical standards are known to be easy-to-get straightforward. Nevertheless, there is a cost associated with the limitations that should be overcome from these approaches, such as the production of toxic by-products or the lack of biocompatibility of the products. Therefore, new methods are needed, and green chemistry offers itself as a suitable answer.

METHODS: In this research, tellurium nanowires were synthesized using a green synthesis methodology (TeNWs). Then, they were used as a template for the synthesis of metallic nanoparticles in an easy and straightforward method with no need of reducing agent that was completed within 1 minute of reaction. Nanoparticles were characterized, and the synthetic process was compared with the ones described in literature, with the aim to compare the methods in terms of chemical needed, reaction conditions and economic implications. Other structures containing both metallic nanoparticles and nanowires, known as synergy, were also obtained in the process of synthesis. Besides, biocompatibility and anticancer tests of both structures – the synergy and the nanowires - with human tissue were accomplished, growing human dermal fibroblast (HDF) cells and melanoma cells in media in the presence of both nanosystems. After an incubation time of 5 days, the cell growth was analyzed using MTS assay. Furthermore, antibacterial properties were tested.

RESULTS & DISCUSSION: The experiments showed that the use of green nanostructures enhanced the growth of the cells in comparison with the control. Furthermore, anticancer and antimicrobial studies showed an improved performance of the synergetic structure compared to the bare nanowires structures, causing a higher depletion of cell viability.

CONCLUSIONS: Thus, here green-synthesized nanostructures were demonstrated to overcome traditional chemistry approaches. In addition, they can be considered a suitable tool for the controllable and quick growth of metallic nanoparticles. Moreover, green synergetic nanostructures have been proved to present enhanced biocompatibility, anticancer and antibacterial properties than previous synthetized TeNWs.
Evaluation of tendon and skin fibroblasts for scaffold-free tendon tissue engineering using macromolecular crowding technology

INTRODUCTION: Human tendon injuries exert healthcare expenditures exceeding €145 billion per year. Current repair procedures usually rely on tendon tissue grafts, which have a limited regenerative efficacy. Tissue equivalents produced in vitro by scaffold-free tissue engineering (SFTE) show promise for tissue regeneration but the long culture times that are necessary for their production hinder their clinical translation [1]. Macromolecular crowding (MMC) is a biophysical phenomenon that accelerates in vitro matrix deposition by several orders of magnitude [2], decreasing the production times of tissue equivalents in vitro. Both tendon (TFs) and dermal fibroblasts (DFs) have shown good performance in tendon regenerative settings and show promise for tendon SFTE. Herein, we sought to compare the performance of TFs and DFs in tendon SFTE by using MMC technology.

METHODS: Human TFs and DFs (25,000 cells/cm²) were treated with MMC (10 μg/ml) and 100 μM L-ascorbic acid phosphate 24h after their seeding. Medium without MMC was used as control. Media were changed every 3 days and read-outs were performed 4, 7, and 10 days after plating. Cell morphology, proliferation, viability and metabolic activity were assessed. Collagen deposition and matrix metalloproteinases (MMPs) production were analyzed by SDS-PAGE and gelatin zymography, respectively. Different tendon markers were analyzed at the gene and protein levels by means of RT-qPCR and immunofluorescence. Additionally, the proteomic profiles of TCs and DFs treated with MMC were elucidated by means of nLC-MS/MS analysis.

RESULTS & DISCUSSION: Cell morphology, proliferation and viability were not affected by MMC, whilst metabolic activity was slightly decreased in the presence of MMC. Collagen deposition was increased by MMC in TCs and DFs in a very similar fashion. MMPs secretion profile of TCs and DFs showed great similarity and was not affected by MMC. Also, great similarities in the expression of tendon markers by TCs and DFs were found by immunofluorescence and RT-qPCR. nLC-MS/MS provided in great detail the global protein expression profile of TCs and DFs treated with MMC.

CONCLUSIONS: TCs and DFs showed great phenotypic similarity under our experimental conditions. Collectively, these results show that DFs may be a promising alternative to TCs for tendon SFTE.

INTRODUCTION: One of the biggest challenges in the field of tissue engineering is how to achieve a functional integration of the implanted constructs with the host vasculature. This process demands the design of a new generation of smart biomaterials capable of stimulating angiogenic processes by releasing chemoattractant agents. Current methods to evaluate this process involve either the use of in vitro models that poorly represent the actual human physiology or in vivo assays which have many limitations such as their high cost or genetic interspecies differences. The goal of this work is to design a microfluidic 3D cell culture device that can better mimic human physiology to optimize the design of such biomaterials.

METHODS: Two designs of the microfluidic platform were created using CAD software. In both cases there is a main cell culture chamber flanked by two media channels. In the first design, these features are connected by an array of microchannels (2x2 µm²), while in the second design, both features are in direct contact and microposts are used to confine the cells in the main chamber. After the master was obtained, PDMS replicas were created by standard soft-lithography. A finite element analysis of the device was performed to model mass transport and study the generation of biochemical gradients. Experimental validation of the transport model was performed using a fluorescent dye. Finally, the possibility to create an endothelial tissue inside the device was tested using HUVEC cells embedded in a fibrin gel. Viability and morphology were assessed by fixing the cells after 3 days of culture and performing an immunostaining with DAPI and phalloidin.

RESULTS & DISCUSSION: both microfluidic platforms were successfully fabricated, and a gradient could also be generated in both devices, being the slope for microchannel design much steeper (-30 mM/ml) than in the micropost design (-5.8 mM/ml). The HUVEC culture in 3D was also viable, while the cells didn't form an interconnected network.

CONCLUSIONS: Collectively, these data illustrate that the design based on the micropost architecture outperforms the microchannel one, as it allows to obtain a wider range of concentrations relevant to study cell migration. It was also possible to create an endothelial tissue inside the devices using HUVEC cells embedded in a fibrin gel. Future work will focus on further optimizing this platform by developing a synthetic biomaterial to support controlled endothelial network formation and apply it to test different biomaterials capable of releasing chemoattractant agents such as growth factors, ions, etc.

INTRODUCTION: Tendinopathies represent half of all musculoskeletal injuries worldwide. Inflammation contributes to both tendon healing and to tendinopathy but the mechanisms leading to pathology are unknown. In previous studies, we showed that pulsed electromagnetic field (PEMF) actuation modulates tendon cell behaviour in inflammatory environments, and that PEMF actuated membranes could influence inflammation responses in a rat ectopic model [1]. Herein, we propose to investigate the synergistic action of PEMF and magnetic responsive membranes in i) tendon cells treated with IL-1β to mimic a tendinopathy environment and ii) the phenotype of macrophages cultured on the membranes.

METHODS: Human tendon cells (hTDCs) were seeded (5000 cells/cm²) on membranes of starch and polycaprolactone impregnated with iron oxide nanoparticles before treatment with IL-1β. Afterwards, hTDCs were exposed for 1h to a 5Hz 4mT PEMF with a 50% duty cycle. The phenotype of human macrophages on PEMF actuated membranes was assessed to confirm their immunomodulatory potential.

RESULTS & DISCUSSION: The expression of pro-inflammatory (TNFα, IL-6, IL-8, COX-2) and ECM remodeling (MMP-1,-2,-3 and TIMP-1) genes tend to decrease in PEMF actuated membranes, while anti-inflammatory gene expression (IL-4, IL-10) increases. Also, CD16++ and CD206+ were only detected in macrophages cultured on PEMF actuated membranes.

CONCLUSIONS: PEMF actuated membranes show a modulatory effect on the inflammatory profile of hTDCs. The expression of anti-inflammatory/repair markers in macrophages highlights the immune modulatory potential of PEMF actuated membranes envisioning tendon healing strategies.

Development of a biomimetic, functional and vascularized peripheral nerve model

A. Malheiro, P. Wieringa, L. Moroni

Presenting Author: Afonso Malheiro, a.malheiro@maastrichtuniversity.nl
1MERLN Institute for Technology-Inspired Regenerative Medicine, Maastricht University, The Netherlands

INTRODUCTION: In vitro peripheral nerve (PN) models remain underdeveloped. To overcome this, we have devised a simple and inexpensive method to fabricate a 3D biomimetic and functional peripheral nerve model. Using this model, we have shown its application for drug testing as well the ability to incorporate other target tissues, such as vasculature.

METHODS: We devised a co-culture platform composed of an aligned electrospun scaffold, containing primary Schwann cells (SCs) and PC12 cells, and a fibrin hydrogel. We carried the co-culture for 7, 21 and 28 days and at every timepoint evaluated the effect of PC12 priming and fibrin hydrogel addition, by measuring neurite network formation and neurite myelination. Through calcium imaging we assessed cell functionality. To show drug response, we applied suramin (100µM), in the presence or absence of the inhibitor Nimodipine (300µM). The following day we evaluated cell viability, apoptosis and tissue morphology. To build the neurovascular construct, we first co-cultured SCs and PC12 for at least 7 days, then added a fibrin hydrogel containing endothelial cells (hMVECs) and human fibroblasts, and carried this culture for at least 10 days longer.

RESULTS & DISCUSSION: Within 7 days of culture on aligned nanofibrous scaffolds, the SCs developed Büngner Bands-like structures, and produced robust amounts of nerve ECM proteins, such as laminin, fibronectin and collagen IV. 7 days after adding PC12, these developed aligned neurites that were longer and more numerous, when SCs were present (compared to no SCs control). Priming PC12 before seeding also improve neurite length and density in all conditions compared to non-primed cells. Fibrin gel addition led to neurite length reduction but also to an increase in the network volume. For longer co-cultures of 21 and 28 days, neurites became myelinated with evidence of nodes of Ranvier formation. Myelination area was significantly increased in conditions with primed PC12 compared to the non-primed counterparts. This area remained constant from day 21 to day 28, but the thickness increased overtime. When fibrin gel was added, 3D volumetric myelin bands were observed and the myelin thickness was slightly increase compared to bare scaffold conditions. Drug test studies revealed that PC12 neurites are sensitive to suramin (at 100µM, 24h treatment), evidencing a decrease in cell viability and neurite length/density and increase in apoptotic activity (compared to untreated samples). When simultaneously adding nimodipine (300µM), there was a partial rescue, denoted by an increased viability and neurite length/density compared suramin only conditions. Finally the neurovascular constructs showed the successful formation of a mature vessel network (vWF+, Ve-cadherin+) intertwined with the neurite network. Moreover, it was possible to observe neurovascular patterning, with neurites following the vessel direction.

CONCLUSIONS: We successfully developed a 3D PN model that is biomimetic, functional and allows for drug testing. Moreover, addition of target tissues is also possible, as shown with addition of vasculature.

INTRODUCTION: Synthetic vascular grafts cause inflammation that leads to thrombosis and intimal hyperplasia. To avoid these complications, we produced a completely biological graft by weaving threads of human extracellular matrix (ECM) \cite{1}. Currently, threads are obtained from sheets of ECM synthesized by human skin fibroblasts cultured in vitro \cite{1}. Here, we propose the use of human amniotic membrane (HAM) sheets, which are readily available in large quantities and at minimal cost. Moreover, the HAM has low immunogenicity and proven clinical safety \cite{2}. In a first step towards the production of vascular grafts, the objectives of this study were to 1) perform a HAM mechanical cartography to better understand the properties of this material and, 2) to produce and characterize HAM threads.

METHODS: Fetal membranes were collected after a cesarean delivery at term. HAMs were sampled using a standardized pattern in 2 areas (placental and peripheral) and 2 directions (radial and circumferential). Tensile tests were then performed at 1\% length/s to record force (F\textsubscript{max}) and strain (S\textsubscript{max}). T-test or one way ANOVA were considered statistically significant when p<0.05. HAM was cut in ribbons with a custom cutting device and twisted at different levels to produce threads.

RESULTS & DISCUSSION: The 8 HAMs studied had similar mechanical properties. On average, 103 ± 10 samples were analyzed per membrane. Intra-tissue variability highlighted the fact that placental and peripheral areas could be considered as mechanically distinct. Overall, placental HAM was significantly stronger by 82 ± 45 \% and more stretchable by 19 ± 6 \% than its peripheral counterparts. Our results also demonstrated that placental, but not peripheral, HAM presented isotropic mechanical properties. Cryo scanning electron microscopy showed that threads surface was very smooth and transmission electron microscopy showed that collagen fiber compaction increased with twisting resulting in a decrease of thread diameter and changes in mechanical properties.

CONCLUSIONS: To our knowledge, this cartography is the most detailed analysis of HAM mechanical properties. This data is relevant to many fields since HAM is used in clinical applications and in many tissue engineering projects. Our next step will be to use HAM threads for the development of a new woven vascular substitute.

INTRODUCTION: Glioblastoma multiforme (GBM) is the most malignant form of central nervous system. The highly lethal nature of this tumour mainly originates from its exceptionally infiltrative and dispersive nature that contributes to tumour angiogenesis and metastasis. 3D models of cancer are increasingly utilized to provide insight into how the tumour microenvironment regulates its behavior. We engineered biomimetic vascularised tumouroids to provide insight into how microenvironmental cues of the tumour stroma, such as ECM density and hypoxia, regulate GBM neovascularisation and invasion along blood vessels.

METHODS: Patient-derived GBM cells and Human Umbilical Vein Endothelial Cells (HUVECs) were used to construct spheroids by the hanging drop method. These spheroids were then embedded in fibrin gels, with concentrations of 2.5, 5 or 7.5 mg mL⁻¹, containing Human Dermal Fibroblasts (HDFs). The experiments were carried out under hypoxic (1% O₂) or normoxic (20% O₂) conditions. Time-lapse images were taken using inverted fluorescent microscopy and then deconvolved using a Zeiss module. HUVECs vessel area and length were analysed using ImageJ Angiotool Software. GBM co-localization along blood vessels was quantified using the Pearson’s correlation coefficient.

RESULTS & DISCUSSION: This tri-culture method triggered robust HUVECs angiogenesis creating lumenised capillaries that sprouted radially outwards into the surrounding fibrin gel. Low oxygen concentration increased GBM invasion but significantly decreased the development of endothelial networks as measured by vessel area and length. Interestingly, high fibrin gel concentration led to an increase in the percentage of GBM cells that invade along the blood vessels (see Figure 1).

CONCLUSIONS: The results demonstrate that the tissue-engineered GBM model can be used as a novel platform to study GBM invasion along blood vessels in vitro. We observe biomimetic GBM invasion on the basal surface of the blood vessels, which is reported to occur in vivo.

Figure 1: Typical fluorescent images of the vascularised tumouroid model taken at day 3. HUVECs (red) and GBM cells (green) are embedded in 2.5 mg mL⁻¹ (left) and 7.5 mg mL⁻¹ (right) fibrin gels containing HDFs under normoxia.

INTRODUCTION: Ovarian carcinoma (OC) presents a significant challenge in designing effective drug treatment and in understanding cellular processes during disease progression, especially during the transition from a solid form of the tumor to a detached spheroid form, in effusion. Emerging evidence shows the various functions of sphingolipids, and specifically, Sphingolipid-1-phosphate (S1P) as regulators of cancer progression [1]. Herein, we ventured to construct a 3D OC in vitro culture system using alginate macroporous-based scaffolds and dynamic perfusion bioreactor [2] to mimic the 3D tumor microenvironment.

METHODS: The basal mRNA levels of S1P receptors’ expression and relative proportion were established by RT-PCR analyzing of over 250 samples from ovarian cancer patients. 433 OC cells were cultured in 4 different culture forms for X days: (a) monolayer (b) seeded into alginate porous scaffolds, under static conditions, (c) alginate scaffolds in perfusion bioreactor, (D) cell spheroids. RT-PCR analysis was conducted after 3 days’ culture.

RESULTS & DISCUSSION: Cultivation of 433 cells within alginate scaffolds, cultured under flow velocity of 50 mL/h resulted in S1P receptor mRNA expression levels similar to those of primary samples from OC patients. Moreover, the relative proportions of each receptor were also similar to those of the primary tumor samples. By contrast, no such similarity was detected for monolayer and spheroid cultures. Confidence Interval comparison was performed, supporting the bio-similarity of the dynamic model results to those of the solid tumor results.

CONCLUSIONS: A novel in vitro model was designed and established for Primary OC, appropriated for experiments with a relatively large number of the samples.

ACKNOWLEDGEMENTS: Financial support was received from Azrieli college (AB).

Emulsion-templated porous polymers as scaffolds for 3D cell culture and tissue engineering
A. M. Eissa

Presenting Author: Ahmed. M. Eissa, a.m.eissa@warwick.ac.uk
Department of Chemistry, University of Warwick, Coventry, U.K.

Highly porous polymeric materials can be prepared by emulsion templating technique, whereby a high internal phase emulsion (HIPE) is created in which the continuous (non-droplet) phase contains polymerisable monomer(s). Polymerisation then results in a well-defined macroporous polymer (foam), known as a polyHIPE. The nature of the formation of PolyHIPEs creates a highly porous, interconnected monolith structure, the architecture of which can be tightly controlled. These polyHIPE materials can serve as scaffolds for the culture of cells and, ultimately, tissues in 3D, allowing cells to mimic their native structure and function in vitro. Applications of these polymeric scaffolds are foreseen in 3D cell culture, tissue engineering and regenerative medicine. However, one potential limitation of these polyHIPE materials as 3D cell scaffolds is surface chemistry. Cells in vivo are typically surrounded by a complex extracellular matrix that contributes to cell anchorage and function. For example, it is well known that hepatocytes (liver cells) possess a galactose-binding cell receptor (asialoglycoprotein). The presence of galactose residues on the surface of polyHIPE scaffolds could improve hepatocyte adhesion and function while growing on the scaffold, leading to enhanced performance in liver tissue engineering applications. This presentation will describe different preparation strategies of such polyHIPE scaffolds and their subsequent functionalisation with biomolecules in order to further improve cell adhesion and function while growing on the scaffold, mimicking the native extracellular matrix (ECM). Initial cell culture experiments with primary rat hepatocytes and human endometrial stem cells will be presented. Subsequently, the application of these polymer materials as matrices for in vitro 3D cell culture and tissue engineering will be discussed. One current project involves the utilisation of such polymer scaffolds to create an advanced 3D model of human endometrium (womb in a dish) in order to study normal and pathological embryo implantation events that cannot be studied directly in humans.

INTRODUCTION: The regeneration of craniofacial bone tissues presents a unique challenge due to their complex structure, multiple embryonic origins and distinct molecular mechanisms of development [1]. With their developmental relevance to the craniofacial skeleton, high expandability and potential for personalized medicine, human pluripotent stem cell derived neural crest stem cells (NCSCs) are an attractive cell source for craniofacial reconstruction. However, current clinical utility is limited by a lack of understanding of the derivation of ectomesenchymal stem cells (eMSCs) from NCSCs, their phenotype, differentiation potential and osteogenic capacity.

METHODS: NCSCs were derived from human embryonic stem cells following [2]. They were differentiated to eMSCs on PDMS substrates of differing stiffness for 7 days and characterized. After 21 days of osteogenic differentiation in PCL-TCP scaffolds, eMSCs were implanted in rat cranial defects to assess bone regeneration.

RESULTS & DISCUSSION: Lower substrate stiffness increased the multipotency of derived eMSCs. This process was regulated by Rho-ROCK mediated CD44 signaling, via modulation of PDGFR signaling. We benchmarked eMSCs to mesodermal bone marrow MSCs (BM-MSCs) and found them to be functionally and transcriptionally distinct, with persistent expression of cranial neural crest markers. eMSCs showed comparable osteogenic and chondrogenic ability to BM-MSCs in 2-D in vitro culture, but lower adipogenic ability. They exhibited greater proliferation than BM-MSCs and comparable construct mineralization in 3-D polycaprolactone-tricalcium phosphate (PCL-TCP) scaffolds in vitro. eMSC derived osteogenic constructs were more proliferative, less mature and showed differential levels of FGF signaling compared to BM-MSCs. Both eMSC and BM-MSC seeded scaffold constructs could enhance bone regeneration in a rat critical-sized calvarial defect model.

CONCLUSIONS: Our study sheds light on the mechanisms affecting the multipotency and osteogenesis of eMSCs and demonstrates the potential of eMSCs for future clinical applications. Our results indicate that the ontogeny of an MSC population impacts both its phenotype and functionality.

INTRODUCTION: To address current limitations in nerve guidance conduits (NGCs), a filled NGC with an internal matrix consisting of aligned microporous channels was fabricated. To allow for increased rates of Schwann cell migration, this study will investigate the incorporation of extracellular matrix (ECM)-derived neuro-conductive macromolecules into microporous NGCs.

METHODS: ECM molecules were incorporated into a selected matrix of collagen-chondroitin sulphate (Coll-CS). ECM combinations were incorporated into Coll-CS slurries and directionally freeze-dried. Effect of ECM incorporation on the porosity and pore alignment was assessed using SEM. Pro-regenerative effects of ECM scaffolds were assessed using primary rat isolates in 2 and 3D culture for 14 days with lead candidates progressing to in vivo testing in a rat sciatic nerve model.

RESULTS & DISCUSSION: ECM-NGCs were found to be highly porous and uniform throughout. There were significant increases in Schwann cell proliferation with the highest levels observed when multiple ECM macromolecules were present. 3D ex-vivo culture found that small alterations in the ECM composition elicited significant changes in neural regeneration potential (figure 1). Up to 50% recovery in stimulation response was observed at 4 weeks with further tests ongoing (figure 2).

CONCLUSIONS: These findings clearly demonstrate the benefit of ECM macromolecule incorporation and highlight the high impact of ECM combination selection.

INTRODUCTION: Platelet lysate (PL) gained great interest in medical fields due to platelets’ role in the immune response against infections and tissue healing¹. The antimicrobial properties of PL patches are already known²; however, the main mechanisms or elicitors for its antibacterial (AB) activity are still unclear. Herein, we aimed at unraveling the AB action mechanisms of PL patches against Staphylococcus aureus.

METHODS: PL was prepared by freeze/thaw cycles¹ and concentrated by ultrafiltration. AB activity of PL patches ¹,² was evaluated against S. aureus using an overlay gel assay. PL patches were further characterized by Blue Native-2D Electrophoresis and 2D Electrophoresis under denaturing native conditions to identify AB proteins, and identified by MALDI-TOF/MS. The permeabilization of S. aureus outer and inner membranes by PL was investigated using fluorescence microscopy, after staining with PI and SYTOX Green. The expression of S. aureus genes leading to bacterial adherence and formation of biofilm, were evaluated.

RESULTS & DISCUSSION: PL exhibited AB activity against S. aureus. Native-PAGE and 2D electrophoresis showed different proteins present in PL with similar isoelectric points (pH 3-10 and 5-8) but with different molecular weights. MALDI-TOF data showed the presence of unresolved peaks around 25-30kDa, and 70kDa. The permeabilization assays suggest that PL damages S. aureus membranes.

CONCLUSIONS: Herein, our results demonstrate AB activity of PL against S. aureus. PL is composed by different proteins or complexes with similar isoelectric points (at pH 5-8), but different molecular weights as identified through proteomics tools. Further studies will be made to unveil PL effect on microbial activity, elucidating their main mechanism of action.

INTRODUCTION: Mesenchymal stem/ progenitor cells (MSCs) are applied in experimental clinical procedures as a promising tool in regenerative medicine. Although MSCs from different tissues exhibit many common characteristics, some markers and biological properties are different and depend on their tissue of origin [1]. In this study, we characterize the biological properties of MSCs during long-term culture isolated from: bone marrow (BM-MSCs), adipose tissue (AT-MSCs), skeletal muscles (SM-MSCs), and skin (SK-MSCs).

METHODS: Tissue samples were collected from deceased donors and from limbs amputated due to critical limb ischemia (study approved by a local Bioethics Committee). BM-MSC (n=8), AT-MSC (n=7), SM-MSC (n=9) and SK-MSC (n=7) were isolated and long-term cultured for 10 passages (P) in standard conditions. MSCs markers for: CD73, CD105, CD90, proangiogenic CD146, PDGFRα, CD31, and multipotency PW1 were examined by flow cytometry, and immunofluorescence. Multipotency was evaluated for osteo-, adipo- and chondrogenic potential. Stemness markers for mRNA for Sox2 and Oct4, and genetic stability for p53 and c-Myc were assessed using qPCR. 27 bioactive factors were screened using the multiplex ELISA array. Spontaneous fusion by co-culture of SM-MSC with BM-MSC or AT-MSC stained with PKH26(red) or PKH67(green) was assessed.

RESULTS & DISCUSSION: All examined MSCs showed the basic MSC phenotype CD73, CD90, CD105 stable up to P10. However, their expression decreased with the age of culture, as confirmed by fluorescence intensity. The proangiogenic properties of MSCs were confirmed by CD146 and PDGFRα expression, but long-term culture is unfavorable for maintaining the proangiogenic function of examined MSCs, apart from BM-MSCs. All examined MSCs, except BM-MSCs, expressed PW1, a marker associated with differentiation capacity and apoptosis. Only SM-MSC express CD56, a marker characteristic for muscle progenitor cells, stable up to P5. The stemness markers Sox2 and Oct4 were detectable in all examined tissue-specific MSCs during long-term culture. All examined MSCs were stable in terms of p53 and c-Myc, however their expression differs between passages. The differentiation capacity of BM-MSCs and AT-MSCs was maintained up to P10. In contrast, SK-MSCs and SM-MSCs had a limited ability to differentiate into adipocytes. ELISA revealed secretion of IL-6, IL-8, MCP-1, MIP-1β, VEGF in different concentrations, depending on MSC niche. AT-MSC and BM-MSC were able to fuse with SM-MSC population.

CONCLUSIONS: Variability in biological properties of MSC from different tissue niche may influence on MSC quality and therapeutic potential. Long-term culture affects the biological properties of MSCs obtained from various tissues. The source of MSCs and the number of passages should be considered in the preparation of MSCs for regenerative medicine.

INTRODUCTION: Current treatment failures of high risks Neuroblastomas (NB) may be due to the lack of in vitro models for studying, in a given patient, the efficacy of potential therapeutics, including those aimed to enhance anti-tumor immune responses. We here propose 3D alginate-based hydrogels as pre-clinical culture systems where to test recent therapeutic approaches.

METHODS: Cell-laden NB alginate spheres were prepared by using two different neuroblastoma cell lines: HTLA-230, SH-SY5Y and cultured up to 1 week. The morphology of the hydrogels, cell organization, cell viability and proliferation was monitored up to 1 week of culture. We analyzed NB cell-laden alginate spheres, cultured with and without INF-γ, for the surface expression of ligands regulating natural killer and T cell mediated immune responses. NB cells cultured in traditional 2D conditions were used as control for all the tests described above.

RESULTS & DISCUSSION: NB cell lines proliferated within our hydrogel spheres with a rate comparable with traditional 2D cultures, but with a spheroid morphology and a clustered organization, resembling in vivo phenotype. The ligands surface expression analysis highlighted a novel and clinical-relevant constitutive and IFN-γ-inducible NB immune-phenotype in the 3D hydrogels. Interestingly, we analyzed a ligand (PVR) involved in the formation of immune synapses with natural killer cells, crucial for killing of ex-vivo derived tumors. A strong downregulation of PVR, that occurs in vivo, was observed in IFN-γ-treated NB cell-laden alginate spheres (Fig.1) and was not detected in the traditional 2D culture system (data not shown).

CONCLUSIONS: This work highlighted a novel and clinical-relevant constitutive and IFN-γ-inducible NB immune-phenotype when cultured in the 3D hydrogels. In particular, the PVR trend observed in our 3D model well resemble the PVR variations occurring in vivo, which are not well appreciated in 2D standard culture conditions. Thus, 3D hydrogel-based spheres might represent a valid platform where to evaluate the efficacy of personalized interventions aimed to optimize the current and innovative immunotherapies.

Figure 1: A) Picture and optical image of NB loaded alginate spheres. B) Cell viability represented by live/dead images of NB cell-laden alginate spheres after 24 hours of culture. C) Immunofluorescent images of PVR in NB cell-laden alginate spheres cultured a week either in the absence or in the presence of INF-γ
Mesenchymal and neural stem cells coculture for TERM applications in CNS

Disruptions of central nervous system (CNS) architecture are devastating, due to the irreversible process of neuronal death, the limited regenerative capabilities of brain and the current lack of effective treatments. Nowadays, regenerative medicine and cell replacement therapies are very promising approaches to treat the damaged brain [1]. In this context, stem cells represent an important cell source for transplantation therapies, and biomaterials can help in recapitulating the three-dimensional environment of the brain that usually gets compromised in the injured site. Among the different types of scaffolds, hydrogels are very interesting for brain tissue engineering. A few years ago, we have demonstrated that alginate (obtained through CaCl₂ crosslinking) supports and enhances neural differentiation of murine Embryonic Stem Cells with respect to traditional 2D-cultures, and the encapsulated cells spread neurites and form connections among themselves [2]. Currently, we are testing alginate-based hydrogels to support human neural- and mesenchymal-SCs injection into the brain. Indeed, regarding the cells source, both the transplantation of neural stem cells (NSCs) and mesenchymal cells (MSCs) has been reported to elicit beneficial effects by regenerating neurons or secreting molecules and factors that help in the healing process [3]. The surprising ability of MSCs to regulate neural stem cell proliferation and differentiation has prompted research in understanding their interaction with NSCs and their impact on CNS regeneration. At the moment we are focusing on the identification of the best conditions for NSCs and MSCs coculture in alginate hydrogels. We are investigating: the best conditions for NSCs encapsulation, the optimal culture media and culture conditions, whether MSCs can survive in the coculture medium (maintaining their stemness) and setting up a preliminary coculture system. In the setting of the coculture, one of the major difficulties is the use of serum, as it is necessary for MSCs, while pushing NSCs toward glial differentiation. We have thus started to define the culture conditions and investigate whether we can create "compartmentalized" cocultures that would at least partially retain serum. By adding an alginate outer layer to our beads, we were able to retain the BSA (used as a "proxy" for serum) inside the biomaterial, creating a promising approach for coculture. In parallel, we positively observed that MSCs can survive, proliferate and maintain their stemness (CD44+ and CD73+) even in absence of serum, supporting the hypothesis that the use of “compartmentalized” coculture systems with low serum content would likely be exploitable for MSCs culture. In the future, the coculture of MSCs and NSCs would allow in vivo applications such as transplantation in injured animal models for CNS tissue regeneration.

INTRODUCTION: Adult mesenchymal stem cells (MSCs) are a promising candidate for treating tendon injuries. Recent studies have demonstrated that adult MSCs are capable of differentiating down tendon-like cell lineages and can improve tendon healing in animal models [1]. Despite critical limitations and safety concerns, fetal bovine serum (FBS) is still predominantly used for MSC expansion in clinical protocols [2]. Here we present preliminary data on a prototype serum-free medium optimized for in vitro tenogenic differentiation of human bone marrow-derived MSCs.

METHODS: Human bone marrow stem cells were seeded at 30,000 cells/cm² in 24-well plates. Once culture wells reached >95% confluence, cells were cultured in serum-free tenogenic differentiation medium (SF-TDM) and maintained for up to 21 days. Medium change was performed every 3 days. Tenogenic differentiation was assessed via qPCR, immunocytochemistry, flow cytometry, western blot and bilineage differentiation assays, carried out at day 0-3-8-21.

RESULTS & DISCUSSION: qPCR analysis showed that SF-TDM induces early Scx gene expression, which is followed by upregulation of Tnmd, Mkx, Col1, and Col3. Immunocytochemistry confirms Scx expression at early time points. Cells with spindle-shaped morphology and high Tnmd expression are seen in cultures after 21 days in SF-TDM. Moreover, evaluation of collagen deposition clearly indicates that cells cultured in SF-TDM first synthesize a matrix rich in collagen type III, followed by collagen type I, thereby resembling the physiological tendon repair process. Eventually, bilineage differentiation assay indicates that tenogenic lineage-committed cells exhibit decreased capacity to differentiate towards osteogenic and adipogenic lineages.

CONCLUSIONS: This defined serum-free formulation is capable of generating tenocyte-like cells derived from hBM-MSCs in vitro expressing tenogenic markers, such as Scx, Tnmd, TnC, Collagen I and Collagen III.

INTRODUCTION: Linear poly(ethylene oxide) (PEO)-based polymers can be mixed with α-cyclodextrins (CDs) in water to form poly(pseudo)rotaxanes (PPRs), thus obtaining supramolecular (SM) gels with thixotropic and self-healing properties [1]. Moreover, the presence of free CDs can be exploited to encapsulate and release drugs in biological environments. Herein, novel polyurethanes (PUs) were synthesized to improve mechanical properties and stability in aqueous environment of SM hydrogels based on CDs.

METHODS: PUs were synthetized using Poloxamer P407 as diol (PEO 70%wt), 1,6-hexamethylene diisocyanate and two different chain extenders: 1,4-cyclohexane dimethanol (PU: CHP407) and N-Boc serinol (PU: NHP407). PU and CD aqueous solutions were then mixed at different ratios and the resulting SM structures were characterized by Attenuated Total Reflectance Infrared (ATR-FTIR) spectroscopy, Proton Nuclear Magnetic Resonance (¹H-NMR), Dynamic Light Scattering (DLS) and X-Ray Diffractometry (XRD). Self-healing and thixotropic behavior was assessed by rheological characterization. Swelling and dissolution were studied at 37°C and cytotoxicity tests were performed according to ISO10993.

RESULTS & DISCUSSION: ATR-FTIR, NMR, DLS and XRD results proved the formation of SM structures based on PPRs. SM hydrogels were obtained by mixing PU and CD solutions at final PU and CD concentrations of 1-9%w/v and 9-10%w/v, respectively. Gelation kinetics required from 20 minutes to overnight incubation at room temperature to obtain stable hydrogels. Rheological strain-sweep tests showed the ability of the gels to adapt to high strains (up to 500%) recovering the starting properties within 15 minutes. Moreover, some formulations showed an instantaneous recovery of gel state after complete rupture (Fig. 1). PU-based SM hydrogels exhibited good stability in aqueous environment and were non-cytotoxic.

CONCLUSIONS: The good mechanical and biological properties of the designed PU-based SM gels make them promising platforms for advanced drug delivery applications.

INTRODUCTION: When regenerating bone by mimicking the endochondral pathway, the cartilaginous template engineered in vitro acts as a transient substrate to trigger remodeling and new bone formation in vivo. The regenerated bone will temporarily have a mosaic composition derived of both, donor and host cells and, after remodeling it will be entirely host derived. Since the host is only transiently exposed to foreign cells, it has been postulated that non-autologous mesenchymal stromal cells (MSCs) could be potentially used for endochondral bone regeneration (EBR). However, a potential immune reaction against the non-autologous implant could impair the regenerative process. The aim of this study is to characterize endochondral bone formation and the immune response evoked when different types of non-autologous MSCs are implanted.

METHODS: Four groups were included in this study to compare the EBR of autologous and non-autologous chondrogenically stimulated MSCs. Constructs containing MSCs were cultured in chondrogenic differentiation medium for 28 days. The spheroidal constructs were embedded in a 6x3.5x3.5 mm collagen gel and implanted in a critical size femur defect, stabilized with a PEEK plate in Brown Norway (BN) rats. MSCs derived from Dark Agouti rats or humans were implanted in BN rats to obtain an allogeneic and a xenogeneic transplantation, respectively. Collagen only and constructs with embedded BN MSCs represented the negative and the syngeneic control groups. To quantify bone formation over time, μCT was performed at 4, 8 and 12 weeks. At 1 and 12 weeks, samples were explanted and decalcified to analyze the early (n=5) and late immune response and extent of bone formation on histological sections (n=8). In addition, at 12 weeks, lymphocytes were isolated from the superficial inguinal lymph node and co-cultured with the corresponding implanted MSCs as previously described.

RESULTS & DISCUSSION: After 12 weeks, bone formation was highest in the syngeneic group (89.2±11.3 mm³), followed by 37.2±32.6 mm³ for allogeneic, 16.4±5.9 mm³ for xenogeneic, compared to the collagen control (5.96±5.9 mm³). Furthermore, 7/7 defects of the syngeneic control group and 2/8 of the allogeneic group were fully bridged. No full bridges were observed in the xenogeneic or the collagen groups. Lymphocytes-MSCs co-culture showed mild donor-specific T cell proliferation only for the xenogeneic group.

CONCLUSIONS: These data show that non-autologous MSCs can be used for EBR. The closer the donor cells are related to the recipient, the more mineralized tissue formation and defect bridging was observed. Currently, further analyses are ongoing to confirm EBR on histology and to characterize the local and systemic immune responses evoked.

Fracture localisation of osteogenic polymersomes and modulation of their accumulation by Kupffer cell depletion
A.R. Hailes¹,², E. Scarpa¹, J.M. Kanczler¹, J.P. May¹, T.A. Newman¹, N.D. Evans¹,²

INTRODUCTION: Pharmaceutical treatments to aid bone fracture repair are not yet available in clinic. Potential therapies may target signaling pathways involved in fracture repair, but are limited by off-target effects and poor bioavailability at the injury site [1]. Polymeric nanoparticles (PMs) may provide a solution enabling controlled spatio-temporal drug delivery [2]. In this study we test the hypotheses that PMs loaded with CHIR-99021, a Wnt agonist, can activate the Wnt signalling pathway in vitro and in vivo, and that PMs will passively accumulate at a fracture site, when injected at different times points post-injury. Furthermore PM accumulation at fracture sites can be modulated by depletion of Kupffer cells of the liver.

METHODS: A luciferase reporter cell line was exposed for 24 hours to a range of concentrations of free and PM-encapsulated Wnt agonists, BIO (PM-BIO) or CHIR-99021 (PM-CHIR), and luminescence was quantified. To assess activity in vivo, 200 µL of PM-BIO and PM-empty (control) at a concentration of 2 x10¹² PMs/ml were injected IV. Bone and liver tissue was then extracted and processed for qPCR to assess Wnt-related gene expression at 24 and 48 hours. For in vivo studies, a 1 mm drill-hole defect was made in the femur of male MF1 mice. PMs loaded with fluorescent dye, DiR, were injected either 1 hour or 7 days post-surgery, with or without prior Kupffer cell depletion by administration of 5 mg/ml clodronate 2 days prior to surgery. Kupffer cell depletion was confirmed by immunohistochemistry. Whole body and extracted organs were imaged using the in vivo imaging system (IVIS) and fluorescence was quantified.

RESULTS & DISCUSSION: Free and PM-encapsulated BIO/CHIR induced luminescence in vitro, in a dose-dependent manner, indicating Wnt signaling activation. PM-BIO injected in vivo induced no significant difference in Wnt-related gene expression. PM-DiR fluorescence was observed at the site of injury. Intensity was 4-fold higher when PM-DiR were injected 1 hour compared to 7 days post-surgery. Initial quantification suggests lowered liver-specific accumulation after Kupffer depletion with no effect on fracture-specific accumulation.

CONCLUSIONS: PMs loaded with BIO/CHIR induce Wnt signaling in vitro. PMs also accumulate passively in vivo at a target fracture site, during different phases of healing. Future work will investigate the effect of increasing the dose of encapsulated BIO on in vivo Wnt-related gene expression and fracture repair outcome.

INTRODUCTION: Extracellular vesicles (EVs) increasingly gain focus in regenerative medicine for promoting tissue repair and alleviating inflammation. However, there are no standards for EV isolation from patient blood nor for quality assessment owing to lack of knowledge about active components or mechanisms of action. It is known that high, low and very low density lipoproteins (HDL, LDL, VLDL) as well as chylomicrons copurify with EVs during isolation from various body fluids including blood via ultracentrifugation (UC) or size exclusion chromatography (SEC). The aim of our study was to develop an isolation strategy to purify EVs from blood derived products which are already in clinical use. Therefore, we analysed EV preparations from citrate-anticoagulated platelet-rich plasma (CPRP) and hypACT™ serum.

METHODS: Particle concentrations after UC, SEC or a combination of both were assessed via nanoparticle tracking analysis (NTA). EVs were labeled with annexin V (AnnV), CD63 as well as CD41 and analyzed by flow cytometry (FC). Low-density and high density lipoprotein (LDL and HDL) content was determined via FC in EV preparations by labeling of Apolipoprotein A1 (ApoA1) and Apolipoprotein B100/48 (ApoB-100) as well as detection via Western Blot. Presence of EVs was confirmed by cryo electron microscopy.

RESULTS & DISCUSSION: NTA revealed 100-fold higher particle concentrations after SEC than after UC or UC+SEC in both, CPRP and hypACT™ serum. AnnV, CD63 as well as CD41 were detected on EVs via FC. It also revealed efficient clearance of ApoB-100 bearing particles by UC, while ApoA1-positive particles persisted. SEC alone removed ApoA1-positive particles, but failed to remove ApoB-100 bearing particles. The combination of enrichment via UC and purification via SEC enabled efficient clearance of ApoA1 as well as ApoB-100 indicative of removal of HDL and LDL. These findings are also supported by Western Blot analysis.

CONCLUSIONS: EV preparations are commonly contaminated with lipoproteins due to their similar size and density. The coupling of UC to separate EVs from lipoproteins by density and SEC to yield separation by size enabled efficient clearance of lipoproteins from CPRP or hypACT™ serum and obtaining pure EV preparations. The developed isolation strategy will benefit the field of regenerative medicine by avoiding obfuscation of results when testing EV preparations from blood derived products in disease models.

INTRODUCTION: Radiotherapy is an established part of treatment of both primary and recurrent pelvic malignancies. The efficacy of pelvic radiotherapy requires an optimal compromise between tumor control and toxicity to healthy, non-neoplastic tissues. Many cancer survivors, exhibit overlapping symptoms resulting from multiple visceral organ dysfunctions which have been recently recognized as a new pathology called “pelvic-radiation disease”. Up to 50% of these cancer survivors suffer from chronic visceral pain. Persistent pain considerably affects the patient’s quality of life. Stem cell-based approaches using mesenchymal stromal cells (MSC) have proved promising for the development of future therapeutic approaches (http://www.clinicaltrials.gov).

METHODS: Rats were subjected to 27 Grays colorectal irradiation. Visceral hypersensitivity (VH) and involved mechanisms were assessed over time using the visceromotor response to colorectal distention. VH was analyzed following the stabilization of mast cells (MC) by Ketotifen (twice a day for 1 week by oral gavage, 1 mg/ kg/day). Additionally, studies were performed in rats receiving MSC therapy, e.g. intravenously injection of 1.5 or 5 million MSC, 3 or 4 weeks after irradiation.

RESULTS & DISCUSSION: Radiation-induced chronic VH. We demonstrated the involvement of peripheral mechanisms where mast cells play a significant role. MSC treatment decreased the interactions between mast cells and nerve fibers and reversed mechanical VH. In patients treated by pelvic radiotherapy, we also reported increased spatial interactions between MCs and nerve fibers in the rectum [1]. Moreover, we showed that MSC compassionate treatment in patient’s refractory to regular treatment, seems to have substantial benefits on gastrointestinal complications like abdominal pain [2]. Finally, we have recently submitted a dossier to initiate a phase II clinical trial, the aim of which is to assess MSC therapeutic benefit on hemorrhage and pain in patients subjected to pelvic or abdominal radiotherapy (“PRISME”, protocol number: P130935; EUDRACT 2014-001462-99; NCT02814864).

CONCLUSIONS: Our work will provide new insights into the follow-up of the MSC efficiency in the treatment of VH and co-morbidities associated to “pelvic radiation disease”.

INTRODUCTION: Neurorprosthetic electrodes are routinely used in clinic to treat multiple diseases of the central nervous system including Parkinson’s and Alzheimer’s disease [1]. However, studies indicate that, in situ, mechanical traumas due to the insertion and micromotions of the electrode results in an adverse tissue response characterized by glial scar formation and electrode encapsulation [2]. In this study, we aim to develop an inflammatory model using fluid shear stress on neural cell populations to reproduce gliosis in vitro.

METHODS: Using a parallel-plate flow chamber system, ventral mesencephalic mixed primary cells were exposed to different level of pressure-driven fluid flow allowing to apply a defined shear stress (from 0.1 to 4 Pa) for either a 5-minute pulse to reproduce the insertion only, or up to several hours to mimic micro-motions between the implant and the tissue. The cells were then kept in culture for 14 days before being assessed for gliosis hallmarks. The morphology and protein expression of neurons and glial cells were quantified by image analysis. qPCR and Western -blots were used to detect the expression level of neuroinflammatory proteins.

RESULTS & DISCUSSION: Data have shown that the applied shear flow leads to astrocyte reactivity and inflammatory environment. Shear stresses from 0.1 to 4 Pa have all significantly increased the GFAP protein expression, number and size of astrocyte cells (Figure 1), along with the up-regulation of several neuronal pro-inflammatory markers and reactive oxygen species.

CONCLUSIONS: In conclusion, we developed an in-vitro model using parallel flow shear stress that mimics damages at the interface of the neuro-electrode. This model will certainly be a precious tool for future researchers developing anti-inflammatory and anti-gliosis biomaterial approaches.

INTRODUCTION: Peripheral nerve transsections can lead to tactile loss and complete paralysis of the upper or lower limbs. Rapid regeneration is the key for an optimal recovery of motor functions, but so far clinicians do not have effective tools to repair wide nerve gaps when autograft is not possible [1]. Our goal is to produce a fully autologous viable nerve tube (NT) in which a network of capillaries is developed by seeding endothelial cells (ECs) for rapid vascularization and Schwann cells (SC) for axonal migration. These nerve tubes containing EC and SC’s (NTECSC) could allow a faster recovery for patients with major peripheral nerve transsections by supporting better axonal migration, an essential aspect for a functional recovery.

METHODS: NT’s consist of human fibroblast sheets and seeded with both EC and SC’s which are rolled to form a filled tubular structure. NTECSC were implanted in immunodeficient RNU rats to repair a 15 mm sciatic nerve defect. Graft remodeling is followed by axonal migration quantification using immunofluorescent staining of neurofilament M after 2, 4 and 8 weeks of implantation.

RESULTS & DISCUSSION: After NTECSC were successfully implanted in rats, their internal structure was quickly remodeled. A revascularization was observed along the entire tube length as early as the 4th week post-implantation. Red blood cells were presented in the pre-establish human capillaries showing the effectiveness of the anastomosis. Nerve fibers migrated and reached the distal nerve stump after 8 weeks. Axonal migrations over short distances were similar to the autograft control. Moreover, myelinated fibers are present in the NTECSC.

CONCLUSIONS: The development of a pre-vascularized NT with autologous ECs may greatly increase the speed of blood vessel reconnection in the graft. This fast vascularization is an essential parameter to facilitate axonal migration over long distances in a well-oxygenated environment [2]. In addition, long term SC incorporation within the NT may release neurotrophic factors and improve peripheral nerve regeneration.

INTRODUCTION: Physiological and experimental data highlight the role of the sensory nervous system in angiogenesis, bone repair and regeneration [1]. Our previous work demonstrated that sensory neurons induce the osteoblastic differentiation of mesenchymal stem cells (MSCs) [2]. Here, we study the cellular communication between sensory neurons (SNs) and endothelial cells (ECs) in order to assess the influence of the sensory nervous system on angiogenesis.

METHODS: Rat primary dorsal root ganglia-derived SNs and bone marrow-derived ECs were cultivated using microfluidic platforms. This indirect co-culture approach allows us to better mimic the in vivo physiological microenvironment by physically separating the cellular bodies of both cell types. Specific immunostaining after 4 days of culture was performed for confocal microscopy and classical transmission electron microscopy in order to study the close interaction between both cell types. Expression of angiogenic markers was assessed by RT-qPCR after 4 and 7 days of mono- and co-culture, and Mmp2/Mmp9 concentration was determined using an assay kit.

RESULTS & DISCUSSION: SNs are able to emit neurites toward the compartments containing ECs, where they closely interact. Among the angiogenic markers analyzed (Tek, Angpt1, CD31, VegfA, Col4 and Mmp2), a significant up-regulation of VegfA and Mmp2 was detected in ECs co-cultured with SNs. In particular, after 7 days of culture, ECs show a 20-fold upregulation of Mmp2 in presence of SNs. Further analysis showed that Mmp2/Mmp9 enzyme concentration was also significantly increased in ECs when they were co-cultured with SNs compared to the mono-culture of ECs.

CONCLUSIONS: Our preliminary results suggest that SNs can closely interact with ECs. SNs are able to modulate the expression of vascular endothelial genes and stimulate angiogenesis through ECM remodeling.

INTRODUCTION: Cardiovascular disease is the most common cause of death worldwide [1], but surgical options are restricted by the limited availability of autologous vessels segments, and the suboptimal performance of prosthetic grafts. This calls for advanced materials and fabrication schemes. Here, we describe a one-step electrospinning approach to obtain elastin-like fibrous scaffolds for cardiovascular applications.

METHODS: Chemically-modified elastin-like recombinamers (ELRs) bearing azide and cyclooctyne groups were coaxially electrospun to fabricate crosslinked click-elastin-like fibers. SEM was used to investigate fiber morphology. Cellular studies were carried out with primary human vascular smooth muscle cells (SMCs) and endothelial cells (ECs).

RESULTS & DISCUSSION: We fabricated, in a single step, electrospun elastin-like fibers that were crosslinked via catalyst-free click chemistry [2]. The fibers were structurally stable in aqueous environments at physiological temperature for at least 3 months, and they showed a mean width of 1.45±0.32 µm, which is in the reported range for the native elastin fibers in the vascular tunica media. No catalysts, additives, crosslinking agents or highly toxic solvents were needed, obviating the risk of compromising the cytocompatibility. SMCs and ECs interacted with the fibers, and proliferated, which demonstrates that ELRs’ bioactivity was maintained after the electrospinning. These cells are relevant for cardiovascular tissue engineering as they provide the main extracellular matrix synthesis and hemocompatibility, respectively. Indeed, the potential of the system was demonstrated by fabricating fibrous tubular scaffolds for e.g. vascular bioengineering.

CONCLUSIONS: Here we developed an approach that combines the advantages of the click chemistry and the innovation of the ELRs with the coaxial electrospinning for the obtaining of water stable fibrillar elastin-like structures in a single step under physiological conditions. This represents a significant step in advancing the electrospinning technology to biomedical applications.

INTRODUCTION: During many years of evaluation of the reaction of the human body to metallic implants, various studies have been made to investigate the resistance of several materials at different infections [1, 2]. The aim of the study is to investigate different Ag- containing hydroxyapatite (HA) coatings enriched with SiC obtained by RF magnetron sputtering, against the action of different microorganisms.

METHODS: The coatings were prepared at different deposition conditions, by varying the RF power fed on Ag cathode (0.6 W, 0.9 W and 1.2 W), while maintaining the power fed of HAP and SiC cathode constant (50 W and 15 W, respectively). The detailed conditions are given in Ref. [3]. Thereafter, HAP+SiC+Ag coatings were sterilized for 30 min and incubated with Candida albicans (A), Streptococcus pyogenes (B), Salmonella Typhimurium (C), Staphylococcus aureus (D), for 1 and 7 days of cultivation.

RESULTS & DISCUSSION: The negative reaction means that the growth has failed during experimented time intervals, while positive reaction shows the growth of different microorganisms. Based on the obtained results, one can observe that only sample S2 indicated an antifungal and antibacterial activity, in presence of the concentrated (Conc.) and diluted (Dil.) germ suspensions. Probably for the S1 coating, the Ag content is too low to provide effects, while for S3, the Ag is too high. A very small reaction was observed for uncoated sample in presence of concentrated germ suspension when incubated with Streptococcus pyogenes.

CONCLUSIONS: Based on the results of the study, it can be concluded that a small addition of Ag into HA coatings can improve the antifungal and antibacterial properties of HA.

ACKNOWLEDGEMENTS: The work was supported by the following grants of the Romanian National Authority for Scientific Research and Innovation, CCCDI – UEFISCDI, Project no. 60PCCDI/2018 (MedicalMetMat), no.68/2018 (CoatDegraBac), within PNCDI III, as well the Core Program 2019 and Institutional project no. **ExCeL: Combining extrusion bioprinting on cellulose scaffolds with lamination for perfusable tissue constructs**

A. Shahin-Shamsabadi¹, P. R. Selvaganapathy¹,²

Presenting Author: Alireza Shahin-Shamsabadi, shahinsa@mcmaster.ca

**INTRODUCTION:** Three-dimensional tissue constructs have considerable applications in understanding of human physiology as in vitro models. They accurately mimic physiological responses of natural tissues [1,2] and several methods such as bioprinting have been developed to fabricate them [3]. Previously developed bioprinting techniques have limitations in incorporating multi-materials and cell types and integrating perfusion channels to form thick 3D structures. Here, we report a new method termed ExCeL that combines extrusion printing, xurography, and lamination to create scalable, multi-material, multi-layer constructs.

**METHODS:** This process starts by pretreating the paper with the hydrogel’s crosslinker (calcium (Ca) for sodium alginate). Hydrogel is then extrusion printed which rapidly crosslinks as it wicks into the paper. In order to create 3D structures, the pretreated paper is cut into desired patterns that constitute channels and then bioinks (hydrogel with cells) is printed on it in predefined patterns. Finally, the individually printed layers are stacked on top of each other and allowed to bond through gel penetration and crosslinking to create the final 3D structure.

**RESULTS & DISCUSSION:** Initially the paper scaffold was treated with 1 M Ca (printing speed of 2000 mm/min and flow of 0.5 mL/min) solution to incorporate the cross-linking agent in it. Then paper scaffolds were cut using xurography to create 2 mm sized hollow channel region. Next, bioinks (2 wt% alginate with cells) were printed using gauge 18 needle, speed of 500 mm/min, and flow rate of 0.5 mL/min achieving a print resolution of 1.08±0.07 mm. HUVEC bioinks were printed annular to the hollow channels while 3T3 bioink was printed surrounding it. The printing allowed clear separation of different cells within a homogeneous matrix. Finally, lamination of multiple layers allowed formation of perfusable channels.

**CONCLUSIONS:** In summary, a new bioprinting technique has been developed that is based on printing hydrogel on paper and its in situ crosslinking. Paper provides mechanical stability that thin hydrogel layers lack and allows for patterned printing of complex structures. This bioprinting method has the capability to fabricate structures that mimic some of the biological complexity of tissues in vitro.

INTRODUCTION: Pro-inflammatory cytokines, especially tumour necrosis factor-α (TNF-α) and interleukin-6 (IL-6), play a crucial role in the development and progression of osteoarthritis (OA) [1]. Although the beneficial effects of antibody (Ab) therapy, they present deleterious side effects and inadequate efficacy due to their short half-life. Therefore, this works proposes the immobilization of anti-TNF-α and anti-IL-6 Abs at the surface of polymeric nanoparticles (NPs) to selectively capture and neutralize those cytokines. Our system aims to extend and increase the Abs therapeutic efficacy (NPs protects them from degradation), and to reduce the systemic side effects using intra-articular (IA) delivery.

METHODS: NPs were prepared as previously described [2]. After accessing the maximum immobilization capacity, a co-culture model of inflammation was used to examine the cytokines neutralization effect in vitro. The in vivo therapeutic effect was assessed in an experimental monoarthritis rat model by measuring clinical parameters, nociceptive behaviour (mechanical allodynia - flexion/extension test, and mechanical hyperalgesia - pressure application measurement (PAM)) and histological analysis.

RESULTS & DISCUSSION: The maximum Ab immobilization ability was 10 μg/mL for anti-TNF-α Ab and 15 μg/mL for anti-IL-6 Ab. The biological properties as well as the synergistic effects of the two antibodies were validated in the co-culture system. Indeed, the biofunctionalized NPs with both Abs exhibited a prolonged action and stronger efficacy than free Abs. In vivo experiments confirmed the safety profile and a higher efficacy of the bio-functionalized NPs in comparison with free Abs, since they significantly decreased mechanical allodynia and hyperalgesia. Overall, it was shown the successful reverse of arthritis nociceptive impairments and inflammatory scenario.

CONCLUSIONS: These results clearly demonstrate the beneficial effects and safety profile of the biofunctionalized NPs after local delivery. In conclusion, this approach can lead to a revolution in the OA treatment.

INTRODUCTION: Parkinson’s Disease (PD) is a neurodegenerative condition related with the death of dopaminergic neurons in the substantia nigra and to an increased state of neuroinflammation due to the aggregation of aberrant proteins [1]. Given that glycans may behave as regulators of protein stability [2], it is important to understand how glycosylation relates to PD pathophysiology. Furthermore, the cross-species comparison between human and rat brains may also elucidate the relevance of animal models in terms of brain N-glycosylation in the development of novel biomaterial approaches for tissue regeneration.

METHODS: Brain tissues were homogenised using RIPA buffer and the proteins entrapped in an acrylamide gel. PNGaseF was used to release the N-glycans and 2-Aminobenzamide to label them. The labelled glycans were purified and analysed on HILIC-UPLC, WAX-UPLC and Mass Spec. Further validation was performed using lectin histochemistry on tissue sections.

RESULTS & DISCUSSION: Reproducible chromatographic profiles of 60 peaks, containing glycan structures, for both striatum and nigra were obtained from human brain tissue. These were shown to have high prevalence of mannose and fucose residues. The abundance of 13 peaks is significantly different between the healthy brain regions. Most of the detected glycans in the striatum are neutral (78% both in healthy and PD brains), whereas in the nigra this percentage differs (85% in healthy vs 78% in PD). In the case of rat brains, sialylation differences are seen in the striatum since the binding of SNA-I and MAA lectins differs between healthy and LPS model brains.

CONCLUSIONS: This study presents an UPLC-based method for N-glycan profiling of brain glycoproteins with high reproducibility, both in rat and human tissues. The differences in sialylation in the nigra of PD patients (vs. healthy controls) highlights the involvement of sialic acids in the onset of the disease.

INTRODUCTION: Cardiovascular disease represents 31% of global deaths every year [1], requiring novel options to promote adequate vascularization for tissue substitutes [2]. Herein, we assessed the influence of an external magnetic field on mesenchymal stem cells (MSCs) cultured on magnetic responsive scaffolds, specifically targeting the increased secretion of angiogenic factor VEGF-A.

METHODS: Scaffolds of gelatin (type A, Sigma Aldrich), containing 1% (V/V) Fe3O4 nanoparticles, were fabricated. Human bone marrow MSCs were seeded at 80,000 cells/cm² on top of gelatin scaffolds. A neodymium magnet was placed beneath the cell culture plate to provide low magnetic field intensity (0.08T). Controls include MSCs cultured on scaffolds in the absence of the magnet (0T) and in polystyrene culture plate (TCP), in the absence or exposed to the magnet. VEGF-A expression and respective protein were quantified by rtPCR and ELISA, respectively.

RESULTS & DISCUSSION: The MSCs in the scaffold exposed to the magnetic field expressed increased values of VEGF-A (p<0.0001) and respective protein (results not shown) (p<0.0001) in comparison with the values obtained in the absence of magnetic field. It was also observed an increase in the expression of VEGF-A by the MSCs cultured on TCP under magnetic field (p<0.0001) when compared with the TCP condition in the absence of magnetic stimulation. Sprouting functional assay of endothelial cells (HUVECs) revealed an improvement in the number of tubes and branch points (results not shown) when cultivated in the media from the MSCs cultured in the scaffolds by comparison with the TCP reference (p<0.0001).

CONCLUSIONS: These data illustrate the improvement of the MSCs capacity to secrete VEGF-A when cultured on the scaffolds under the application of a low intensity magnetic field.

REFERENCES
INTRODUCTION: In this work, we used a double channel microfluidic chip with two parallel microchannels (vascular and extravascular compartment) connected by a micropillar constituting a permeable vascular membrane [1]. The microfluidic chip can be used for studying the vascular transport and tissue permeability of nutrients, waste products and drug molecules, and the intravasation and extravasation of cancer cells.

METHODS: The extravascular channel was seeded with 18,000,000 human glioblastoma U87 GFP+ cells/mL embedded in 50:50 matrigel matrix for 72 hours (Figure 1A). The high density of cells allows one to mimic the tridimensional (3D) architecture and replicate “a piece of tumor tissue” in only 24 h. Free Docetaxel (DXTL) was injected in the vascular channel at physiologically relevant flow rates. Different concentrations of DXTL (0.01, 0.1 and 10 µM) were added into the vascular channel for 24, 48 and 72 h.

RESULTS & DISCUSSION: The highest concentration of DXTL (10 µM) has a remarkable deleterious effect on U87 cells over time corroborated also by cell viability measurements. Also, Figure 1B clearly shows the positive influence of flow in cell death after 48 and 72 h. The extravascular channel in the direction of flow exhibits less viable cells as a function of time. 3D images of U87 cells, measuring the same area in different time points, show that the size significantly decreased upon treatment with 10 µM DXTL over time. The cell viability data obtained by measuring the intensity of fluorescence shows that only 10 µM DXTL was able to kill cells after 48 and 72 h.

CONCLUSIONS: This cancer-on-chip model allows us to simulate the in vivo environment of a tumor by means of 3D culture conditions of cells allowing the spatial organization of the tumor resembling a piece of tissue and the dynamic flow of culture medium and therapeutic drugs simulates the real scenario. This 3D dynamic system can also be used to mimic several brain diseases, to test new therapeutic compounds and personalized treatments using cells from patients.

Natural polyphenols reduce the toxicity of soluble Aβ42 oligomers
A.R. Araújo1,2,3, S. Gigante4, L. Moura5, R. L. Reis1,2,3, R. A. Pires1,2,3

INTRODUCTION: Aging and oxidative stress are the main triggers of supramolecular self-assembly of amyloidogenic proteins, such as Amyloid β 1-42 (Aβ42), one of the hallmarks of Alzheimer Disease.[1] Recent studies indicate that Aβ42 toxicity is not derived from the protein aggregates themselves but to their soluble oligomeric structures[2]. Herein, we evaluated the capacity of natural polyphenols[3] to: modulate Aβ42 aggregation; reduce the cytotoxicity of Aβ42 oligomers; and to reduce the presence of reactive oxygen species (ROS) in the biological environment.

METHODS: The polyphenols vescalagin/castalagin were extracted from the outer bark of Cork oak tree. The capacity of these molecules to modulate the Aβ42 fibrillization was evaluated by CD, Thioflavin T, STEM and AFM. The antioxidant potential was accessed by DPPH assay and DCFH-DA dye in the presence H2O2. Cell studies were conducted with SHSY-5Y neuroblastoma cell line. The capacity of these colecules to decrease the cytotoxicity of Aβ42 oligomers was evaluated by Live/dead staining, alamarBlue® assay and immunocytochemistry.

RESULTS & DISCUSSION: CD and Thioflavin T measurements revealed that vescalagin/castalagin was able to remodel the Aβ42 aggregation pathway, through the inhibition of the self-assembly of its oligomers/monomers. These polyphenols were also able to disassemble preformed fibrils/oligomers. STEM and AFM images showed a remodeling and significant decrease of Aβ42 fibril size. DCFH-DA dye results also showed the ability of these molecules to decrease the ROS under cell culture conditions, while reducing the presence of toxic oligomers/fibrils.

CONCLUSIONS: Both vescalagin and castalagin were able to remodel the aggregation process of Aβ42 and rescue cells from oxidative stress (H2O2) diminishing the toxicity promoted through the spreading of Aβ42 monomers/oligomers.

INTRODUCTION: Impaired bone fracture healing is a major, increasing socioeconomic burden. The targeted delivery of therapeutic agents such as acoustically-stimulated microbubbles (MBs) and nanodroplets (NDs) may overcome pharmacokinetic limitations in treatment. Therefore, in this is study, we tested the hypothesis that MB and ND preparations are non-toxic to human bone cells and promote osteoblastic differentiation in human marrow stromal cells.

METHODS: MBs were fabricated using a 9:1 molar ratio of 1,2-distearoyl-sn-glycero-3-phosphocholine (DSPC) to polyoxyethylene(40) stearate (PEG40S), which were hydrated in PBS and sonicated in a two-step process to form a MB suspension. NDs were formed in a similar way using PFP for the core as opposed to room air. A range of volumetric concentrations of MBs (1:100 - 1:2) or NDs (1:100000 - 1:100) were applied to MG63 osteocarcinoma cells for 20 minutes, 40 minutes, 6, 24 or 72 hours. Alamar Blue® test was carried out to quantify cell metabolic activity, as an indicator of cell viability. To determine the effect of MBs on osteogenic differentiation, room air filled MBs were applied to Stro-1+ marrow stromal cells for 14 days. Osteoinduction was tested using alkaline phosphatase (ALP) assay and gene expression studies.

RESULTS & DISCUSSION: DSPC-PEG40S MBs had a dose-dependent effect on cell metabolic activity of MG63 cells over 72 hours; this was significant only at 1:2 concentration (63% ± 6%, p<0.0001). Up to 24 hours, no cytotoxic effects were observed by either MB or ND exposure. MBs in the presence of osteoinductive factors induced the expression of osteoinductive markers (Runx2).

CONCLUSIONS: DSPC-PEG40S MBs and NDs are non-cytotoxic within clinically relevant time frames at suitable concentrations, proving a safe drug delivery method. These results also support in vivo studies reported in the literature to have used up to $8 \times 10^8$ MB/ml in mice [2]. Further studies are taking place to assess the extent of Stro-1+ osteogenic differentiation induced by MBs.

Figure 1: MB exposure to MG63 cells, up to 24 hours, had no cytotoxic effect. However, exposure of MBs for up to 72 hours significantly decreased cell metabolic activity.

INTRODUCTION: To date, one of the key issues in regenerative medicine and tissue engineering is the lack of blood vessels, which ensure nutrient and oxygen transport within the engineered constructs and prevent their necrosis after transplantation. One of the approaches to fabricate the microvasculature is the use of biomaterials that induce vasculo- and angiogenesis, and fibrin is of particular interest to achieve this goal. As fibrin has rapid biodegradability and opacity, this study aimed to synthesize a non-toxic biodegradable fibrin modification which can induce vasculogenesis.

METHODS: We prepared PEG-fibrin conjugates [1] at different molar ratios and characterized their structural (scanning electron microscopy, atomic force microscopy, differential scanning calorimetry [2], small-angle x-ray scattering [2], infrared spectroscopy) and biological properties (cell viability and vasculogenesis assays).

RESULTS & DISCUSSION: PEGylation of fibrinogen allowed us to overcome the mentioned drawbacks and achieve the gel transparency and preserve its biocompatibility. The use of high resolution crystallographic structures of fibrinogen allowed us to perform rigid body modelling in the case of oligomer formation and restore the mutual orientation of the oligomeric species. Atomic force and scanning electron microscopy and other methods together with small-angle X-ray scattering permitted us to achieve a clear picture of the conjugate structure and properties. We revealed that the gel prepared from PEGylated 5:1 fibrinogen (25 mg/mL) using 1:0.2 U protein to thrombin ratio provided the most favorable microenvironment for spreading, growth, and proliferation of fibroblasts and human umbilical vein endothelial cell (HUVECs) and human adipose-derived stem cell (hASC) coculture. Within this gel, hASCs and HUVECs formed cell extensions and cell-to-cell contacts and expressed specific extracellular matrix proteins and vasculogenesis inherent enzymes which were studied via immunofluorescent staining, gelatin zymography, western blot, etc. The morphological development of this coculture within a perfused hydrogel over 12 days led to the formation of interconnected HUVEC-hASC network. Moreover, this gel supported better the formation of multibranched cords than the pure fibrin gel and other modifications. Analysis of tubule growth rate, length, and branching showed that the differentiated ADSCs had higher angiogenic potential than the differentiated hUC MMSCs.

CONCLUSIONS: All data collected allowed us to reveal optimal composition of the modified fibrin gel, which is required for tailored gel formation with the needed particle sizes and homogeneity level for successful cell encapsulation and induction of vasculogenesis.

Coagulation influences properties of extracellular vesicles isolated from autologous blood derived products

INTRODUCTION: Autologous blood derived products gain more and more interest in the field of regenerative medicine due to their ability to stimulate soft and hard tissue regeneration. Platelet rich plasma (PRP) is the most commonly used blood derivative in clinical practice due to its high concentration of platelets and the perceived high growth factor levels. Drawbacks of using PRP is high donor variability, discrepancies among preparation protocols and the presence of cells (platelets, leukocytes) which can evoke cellular processes, especially inflammation, when injected into the host. It is a possibility to isolate only the active components of blood derivatives which may overcome this problem. EVs are particles transporting bioactive molecules (proteins, miRNAs, lipids) and therefore represent novel mechanisms by which signals are communicated among different cell types. In the current study we focused on extracellular vesicles (EVs) isolated from two autologous blood derivatives, PRP and hyperacute serum and investigated whether the clotting cascade influences EV properties.

METHODS: EVs were isolated from citrate-anticoagulated PRP (CPRP) and hyperacute serum using differential ultracentrifugation followed by a size exclusion chromatography. Particle concentration and size were determined by nanoparticle tracking analysis. Cryo-electronmicroscopy was performed to visualize isolated EVs. Expression of miRNAs transported within EVs as well as in their respective input material was analysed by qPCR.

RESULTS & DISCUSSION: Nanoparticle tracking analysis revealed higher particle concentrations and bigger sized EVs within CPRP compared to hyperacute serum. These findings were confirmed by cryo-electronmicroscopy. Profound differences were detected regarding miRNA expresion between the two blood derivatives. 126 miRNAs were identified which were expressed both in input material (PRP or hyperacute serum) as well as in the corresponding EVs. Interestingly, the correlation between miRNAs in EVs and input material was higher in CPRP compared to hyperacute serum meaning that in hyperacute serum miRNAs were identified which were higher expressed in EVs than in the corresponding input material.

CONCLUSIONS: EVs from autologous blood products represent a novel and cell free approach for regenerative strategies. We observed that the clotting cascade (plasma versus serum) has an influence on concentration, size and miRNA expression patterns of EVs. These differences might have an impact on the biological mode of action of blood derived products used in clinics.

INTRODUCTION: Tissue engineering by self-assembly consists of growing cells on surfaces made of thermoresponsive polymers, that allow the production of contiguous cell. In this approach cell-cell junctions and deposited extracellular matrix (ECM) remain intact, which provides a better cell localisation at the site of injury. However, these systems lack the possibility to fabricate multi-layered and three-dimensional cell sheets that would better recapitulate native tissues. Moreover, the fabrication of ECM-rich cell sheets would be highly desirable. This limitation could be overcome by inducing macromolecular crowding (MMC) conditions [1]. Herein we venture to fabricate electrospun thermoresponsive nanofibres to sustain the growth and detachment of ECM-rich tissue substitutes.

METHODS: A copolymer of 85% poly-N-isopropylacrylamide and 15% N-tert-butylacrylamide (pNIPAm/NTBA) was used to produce homogeneous fibres. Human adipose derived stem cells (hADSC) were treated with media containing macromolecular crowders to enhance matrix deposition. Immunocytochemistry was conducted in order to estimate matrix deposition and composition. Adipogenic, osteogenic and chondrogenic assays were performed both with and without the presence of MMC. Non-invasive cell detachment was enabled by decreasing the temperature of culture to 10 °C for 20 minutes.

RESULTS & DISCUSSION: The electrospinning process resulted in the production of pNIPAm/NTBA fibres in the diameter range from 1 to 2 µm. Cell viability, proliferation and metabolic activity revealed that hADSCs were able to grow on the thermoresponsive scaffold. The cells were able to detach as an intact cell sheet in presence of MMC. Moreover, it was demonstrated that MMC, by a volume extrusion effect, enhances Collagen type I deposition, which is one of the main components of the ECM. Histological analysis revealed that in the presence of MMC the cells were able to self-assembled into three dimensional multi-layers. The cells were able to differentiate towards the osteogenic, adipogenic and chondrogenic lineage in the presence of MMC.

CONCLUSIONS: The pNIPAm/NTBA fibres were able to successfully sustain growth and detachment of ECM-rich tissue equivalents. We believe that replacement, repair and restoration of tissue function can be accomplished best using cells that create their own tissue-specific extracellular matrix with a precision and stoichiometric efficiency still unmatched by man-made devices.

INTRODUCTION: Transplantation of donor-derived pancreatic islets or beta cells has the potential to treat diabetes, but is impaired by poor survival and immune rejection. The ELASTISLET project aims at developing a novel biocompatible encapsulation system, based on functionalized Elastin-Like Recombinamers (ELR), to both attract rapid vascularization and provide immune isolation, in order to achieve long-term viability and function of transplanted islets. Integration and survival of transplanted islets depends on the rapid vascularization of the capsule surface, while avoiding invasion with breakage of the capsule integrity. To promote vascularization, ELRs were functionalized with a pro-angiogenic peptide (QK peptide). Here, we sought to determine the optimal concentration of QK-peptide crosslinked to ELR hydrogels which ensure robust, normal and functional vascular growth.

METHODS: ELR hydrogels were functionalized with increasing concentrations of QK peptide (0%, 10%, 50% and 100%) Bulk hydrogels or ELR-coated gelatin microparticles (GMPs) were implanted into the posterior leg muscles (gastrocnemius) of SCID mice. Vascular growth was quantified after 1, 4 and 8 weeks in vivo by histological analysis.

RESULTS & DISCUSSION: Bulk ELR injections showed that both 50% and 100% concentrations of QK peptide significantly increased vascularization compared to controls, whereas the 10% dose was insufficient. Implantation of GMPs coated with 3 ELR layers confirmed that grafting with both 50% and 100% QK induced increased vascularization compared to both empty ELR and uncoated GMPs already after 1 week in vivo. Further, invasion of GMPs by mononuclear cells and blood vessels was not observed and vascular growth was limited to the GMP surrounding area. Remarkably, the vascular response induced by both 50% and 100% QK-ELR: 1) was stable over at least 8 weeks (no regression over time); and 2) did not show any tendency to penetrate the ELR coating and grow inside the coated GMPs.

CONCLUSIONS: QK-functionalized ELRs increase vascularization dose-dependently both in bulk and in the form of thin-layer capsules. This composition could be exploited as an encapsulation strategy in order to improve viability and function of transplanted pancreatic islets or other cell types.

INTRODUCTION: Strategies for endogenous cartilage repair aim to treat cartilage injuries by targeting joint-resident progenitor cells in situ. Previously, we found that silencing microRNA (miR)-221 in human mesenchymal stromal cells (hMSCs) in vitro strongly enhanced their cartilage production in vivo [1]. We here aimed to develop a fibrin/hyaluronan (FB/HA) hydrogel delivery system to inhibit miR-221 in endogenous cells, for in situ guided cartilage repair.

METHODS: FB/HA was loaded with antimiR-221/lipofectamine complexes and the release of antimiR-221 was monitored over 14 days in vitro. FB/HA-mediated transfection of hMSCs was determined by flow cytometry and qRT-PCR. An animal cartilage defect model consisting of bovine osteochondral units implanted subcutaneously in nude mice was employed to assess endogenous cell invasion and cartilage production in vivo.

RESULTS & DISCUSSION: FB/HA functionalized with antimiR-221 strongly retained the inhibitor in vitro (>85% after 14 days). Culture of hMSCs into antimiR-221 loaded FB/HA led to highly effective cell transfection (~80%) and miR-221 knockdown (>99%), as validated by flow cytometry and qRT-PCR, respectively. When hMSCs were seeded on the surface of the constructs, hydrogel invasion by the cells led to miR-221 knockdown within 7 days. Interestingly, the use of lipofectamine was found to be not necessary for hydrogel-induced miR-221 silencing. When implanted in a cartilage defect in vivo, antimiR-221 loaded FB/HA enhanced cartilage production by endogenous cells, with a statistically significant 2-fold increase in the units displaying high cell infiltration. The newly formed tissue showed extensive production of collagen II and good integration with native cartilage and bone.

CONCLUSIONS: We developed a novel hydrogel-based system that induces miR-221 silencing in endogenous cells and enhances endogenous cartilage repair. Our study opens a new avenue for antimicroRNA therapy for cartilage injuries, providing a versatile methodology for in situ guided tissue repair.

INTRODUCTION: Osteoarthritis (OA) is the most prevalent musculoskeletal disease, but no pharmacological treatment is yet available. This lack in anti-OA drugs finds among its causes the inadequacy of present OA in vitro models. OA is a multi-factorial disease leading to pathological changes not only in the cartilage but also in the subchondral bone and in the calcified hypertrophic interzone interfacing these two tissues. Classic in vitro systems do not capture this complexity. Here, building on our recently developed microfluidic techniques [1, 2], we established a 3D microsystem capable of hosting two directly interfaced microtissues and suitable for induction of OA traits through chemical or mechanical stimulation. Specifically, we aimed at generating a cartilaginous layer in contact with a layer mimicking the hypertrophic interzone.

METHODS: Cartilaginous and hypertrophic layers were generated from human articular chondrocytes (AC) and human bone-marrow mesenchymal cells (MSCs), respectively. Cells were embedded in enzymatically formed and degradable poly-ethyleneglycol based hydrogels. Hydrogels’ mechanical properties, cellular density and culture medium were optimized. Specifically, we aimed at a unique culture medium allowing for hypertrophic traits induction in the interzone layer, while maintaining a stable cartilaginous phenotype in the cartilage layer. RT-PCR analyses and immunofluorescence (IF) were conducted on separated and composite constructs at day 14.

RESULTS & DISCUSSION: In single culture, supplementation of both chondrogenic (CH) and osteochondral (OCM), phosphate enriched, media resulted in MSC expressing significantly higher levels of hypertrophic markers (Col10a1, IHH, BSP2 and BMP2, Fig 1b) with respect to ACs. OCM resulted in MSC derived denser calcified tissues, while not changing the capability of ACs to deposit a matrix rich in Glycosaminoglycan and Collagen type-II. Direct coculture allowed reaching a double tissue construct with a direct interface. Present experiments aim at a deeper tissues’ characterization, and investigation of changes occurring following chemical and mechanical induction of OA traits.

CONCLUSIONS: Results demonstrate the potential of the strategy to develop a microfluidic joint on a chip model with possible application in anti-OA drugs screenings.

The effect of ageing on tenocytes cultured in the presence of xenogeneic vs allogeneic serum

INTRODUCTION: Tenocytes can be expanded in vitro to study their characteristics, to understand the mechanisms underlying tendinopathies, or else to obtain a suitable amount of cells for tissue engineering applications. However, tenocytes expansion in vitro has been associated to phenotypic drift (1). Moreover, their synthetic activity as a function of ageing in culture has not been completely assessed to date. The use of macromolecular crowding (MMC) reportedly increases the deposition rate of fibrillar collagens (2). Herein we compare xenogeneic and allogeneic sera as media supplements for the expansion of equine tenocytes (eTC) at three different sub-culture passages, in the presence or absence of MMC.

METHODS: eTC were isolated by migration method from the superficial digital flexor tendons (SDFT) of 5 donor horses. Cells were cultured in the presence of 10% fetal bovine (FBS) or equine (ES) serum. eTC were examined at P3, P6 and P9, in the presence or absence of 75 ug/mL of crowding agent carrageenan. Viability, metabolic activity and proliferation were assessed by calcein AM / ethidium homodimer staining, resazurin reduction and DAPI staining respectively. Collagen type I deposition was assessed by silver staining and immunofluorescence (IF). ECM composition was investigated by IF. MMPs synthesis was assessed by zymography assay. All experiments were performed at days 3, 5 and 7 after seeding.

RESULTS & DISCUSSION: Silver staining and IF showed increased deposition of collagen type I in the presence of MMC and FBS. This result remained steady throughout the examined passages. In the absence of MMC the deposition of Collagen type III was constantly higher in ES, however no difference was observed in the presence of MMC. The highest deposition was observed in P6. Deposition of collagen type IV was generally higher with ES, was not affected by MMC and peaked in P6. Deposition of Collagen type V was dramatically increased by MMC, was higher with FBS and peaked at P6. Collagen type VI deposition was slightly increased by MMC, markedly increased with FBS in P6, while it dropped with ES at P9.

CONCLUSIONS: The present data suggest ES in the presence of MMC at early passages as a preferable choice for the production of extracellular matrix rich, xenogenic free cell sheets applicable to tendon tissue engineering. On the other hand, FBS is clearly preferable for eTC expansion to later subculture passages.

Assessing cell motility on line and pillar microengineered surfaces: An automatic tool to detect and track cells in brightfield microscopy

A. Carvalho¹,²,³, T. Esteves¹,², P. Quelhas¹,², F.J. Monteiro¹,²,³
Presenting Author: Angela Carvalho, angela.carvalho@ineb.up.pt

INTRODUCTION: When studying cell-surface interactions, it is of major interest to evaluate how different topographical stimuli can alter cell functions. Cell motility, essential in many biological processes, is known to be influenced by the surrounding environment. Several software’s have been developed for analysis of cellular motility. However, application on periodic patterned substrates is ineffective, with interference of the patterns on the automatic tracking of cells [1-2]. In this work, we developed a MATLAB-based tool to automate the process of tracking unmarked cells on patterned surfaces.

METHODS: hMSCs were seeded on microengineered SiO₂ surfaces with line and pillar-shape patterns. A spectral Confocal Microscope Leica TCS-SP5 AOBS was used to record time-lapse images every 5 min for a period of 18h. Time-lapse videos were processed using the developed cell tracking tool to obtain information on cell migration distance, velocity, trajectory and persistence. Both automatic and manual modes were tested, as well as manual correction of incorrectly tracked cells.

RESULTS & DISCUSSION: The software accurately detected and tracked cells on both micropatterned surfaces and a flat control. The automatic mode was significantly faster than the manual, also eliminating user subjectivity. Both micropatterned surfaces showed a significantly higher migration distance and velocity when compared to the flat surface. The trajectory and persistence results showed that cell movement was modulated by the underlying topography.

CONCLUSIONS: We proposed a novel approach to detect and track unmarked cells on patterned substrates, by removing the existing background patterns in brightfield microscopy. Cellular behaviour was evaluated in terms of trajectory, velocity, migration distance and persistence. Cells on both microstructured surfaces displayed improved motility parameters when compared with the flat control.

INTRODUCTION: The clinical treatments for tendon lacerations can be compromised by adhesion formation [1,2] due to tendon synovial sheath disruption and aberrant healing. Hence, there is the need for development of novel anti-adhesion systems capable of allowing tendons to glide. One of the most promising approaches relies on the introduction of a biomembrane that acts as a physical barrier for adhesion-forming cells whilst regenerating tendon synovial sheath [3]. Here, we propose a novel hybrid approach that combines electrospinning and 3D bioprinting techniques to produce a bilayer biomembrane for the restoration of tendon synovial sheath integrity and the prevention of post-operative adhesions.

METHODS: Polymeric meshes were prepared by electrospinning, using a 10% w/v solution of poly(ε-caprolactone) (PCL) (Mₐ=50,000) in HFIP and setting process parameters at 1ml/h (flow rate), 20kV (voltage) and 20cm (needle-collector distance) for 1h. Mesh morphology was assessed via SEM and fibre diameter evaluated with ImageJ. Tensile testing of PCL meshes was performed using an Instron 3344 equipped with a 10N load cell at 10mm/min strain rate. 3T3 cells were encapsulated in PGD-α1 self-assembling peptide hydrogel (SAPH) (2×10⁶ cells/ml) and cell-laden constructs were printed using a 3D Discovery. Cell viability was evaluated at 1h, 1, 3 and 7 days post-printing via LIVE/DEAD assay.

RESULTS & DISCUSSION: The spinning process produced PCL meshes with thin fibres (Mean = 0.254 µm) (Fig. 1A) and high mechanical properties (Fig. 1B). Cell-laden constructs with high structural integrity, reproducibility, geometrical and dimensional accuracy were obtained. Good cell viability and proliferation was detected at day 7 post-encapsulation (Fig. 1C). PCL mesh and cell-laden SAPH construct can be combined (Fig. 1D) to create a bilayer biomembrane for restoration of tendon lubrication and prevention of adhesions.

CONCLUSIONS: The thin fibres and high mechanical properties of electrospun mesh provide a physical barrier with good structural integrity. 3D bioprinting allows accurate spatial distribution without affecting cell viability. Moreover, in the proposed approach, ECM-mimicking SAPHs can potentially stimulate cells to produce HA for long-term lubrication.

INTRODUCTION: The craniofacial area is prone to trauma or pathologies often resulting in large bone damages. One potential treatment option is the grafting of a tissue-engineered construct seeded with adult mesenchymal stem cells (MSC). The dental pulp appears as a relevant source of MSC as dental pulp stem cells display strong osteogenic properties, and are efficient at bone formation and repair. FGF-2 and/or hypoxia primings were shown to boost the angiogenesis potential of dental pulp stem cells from human exfoliated deciduous teeth (SHED). Based on these findings, we hypothesized here that these primings would also improve bone formation in the context of craniofacial bone repair.

METHODS: SHED were seeded in dense collagen matrices [1] and cultured in osteogenic medium for 21 days after FGF-2 or hypoxia priming. The level of mineralized nodule formation was assessed by alizarin red and von Kossa staining, and micro-CT analysis. The osteogenic differentiation was evaluated by immunohistochemistry and Western blotting. Matrices were implanted in critical size bilateral calvarial bone defect in immunodeficient mice to assess in vivo bone formation.

RESULTS & DISCUSSION: We found that both hypoxic and FGF-2 primings enhanced SHED proliferation and osteogenic differentiation into plastically compressed collagen hydrogels, with a much stronger effect observed with the FGF-2 priming. After implantation in immunodeficient mice, the tissue-engineered constructs seeded with FGF-2 primed SHED mediated faster intramembranous bone formation into critical size calvarial defects than the other groups (no priming and hypoxia priming).

CONCLUSIONS: This study reveals that FGF-2 priming of tissue engineered constructs formed by dental pulp stem cells from human exfoliated deciduous teeth seeded within plastically compressed collagen scaffolds strongly enhances craniofacial bone regeneration.

3D-printed TPMS-based structures for bone regeneration
A. Diez-Escudero¹, H. Harlin¹,², P. Isaksson², C. Persson¹
Presenting Author: Anna Diez-Escudero, anna.diez@angstrom.uu.se
¹BioMaterial Systems, Department of Engineering Sciences, Uppsala University, SE-751 21, Uppsala, Sweden ²Solid Mechanics, Department of Engineering Sciences, Uppsala University, SE-751 21, Uppsala, Sweden

INTRODUCTION: Triply periodic minimal surfaces (TPMS) have recently been explored as promising geometries for bone replacement as they give the possibility to combine mechanical stability with high porosity and pore interconnectivity [1]. Furthermore, they have a mean curvature close to zero, just like trabecular bone. Additive manufacturing gives the possibility to produce these types of structures in a straightforward way. Here, a combination of such architectures with polylactic acid (PLA), a resorbable polymer, and fused deposition modelling was explored with the aim to provide scalable complex geometries optimized for bone tissue scaffolding.

METHODS: PLA filament of 2.85 mm was used to print the scaffolds using a 0.25 mm nozzle on a FDM Ultimaker 2+. Three porosities (35-50-65%) were generated through nodal equations for each geometry (Diamond, Gyroid, and Schwarz). Specimen dimensions were 12x24 mm², for mechanical testing (n=6), and 15x5 mm² (diameter x height) for cell cultures (n=3). Compression tests were performed at a displacement rate of 1mm/min. Osteoblast-like cells SaOS-2 (50,000 cells/ml) were seeded dropwise, and proliferation was measured after 1, 2 and 4 days. Tissue culture plastic styrene (TCPS) was included as control. Cells were examined after fixation in a scanning electron microscope (SEM).

RESULTS & DISCUSSION: Young’s modulus followed the following trend for 35% porosity: Schwarz (585 ± 28 MPa) > Diamond (421 ± 89 MPa) > Gyroid (278 ± 70 MPa). Scaffolds dropped 1% in modulus after increasing porosity to 50%, and 20-30% for 65% porosities. Cell proliferation was evaluated with respect to control at 1 day and expressed as percentage. Denser geometries showed higher adhesion after 1 day, however, cell proliferation was more pronounced as porosity increased. Cells were only observed inside pores regardless of the type of geometry, depicting a well spread morphology.

CONCLUSIONS: Gyroid, Diamond and Schwarz geometries gave Young’s moduli in the range of cancellous bone (50-500MPa), even at a relatively high porosity (65%). Even though a lower number of adhered cells at 1 day were found on higher porosity scaffolds, the cell studies suggest that increasing the porosity favors cell proliferation at longer times (4 days) on TPMS scaffolds. These results encourage further studies on the effect of TPMS scaffold porosity as a trigger for cell differentiation.

INTRODUCTION: Green and renewable biomaterials are gaining a great interest for the sustainable fabrication of biologically, physicochemically and mechanically relevant scaffolds for tissue engineering applications [1]. Pectins are heteropolysaccharides extracted from plant cell wall and represent one of the most abundant renewable polymers. Recently, pectins emerged as novel and potential candidate as tissue engineering-based biomaterials due to their biocompatibility and non-toxicity. In this work, the fabrication and characterization of porous pectin-based scaffolds chemically crosslinked by (3-Glycidyloxypropyl) trimethoxysilane (GPTMS) is presented.

METHODS: Low methoxyl pectin (from citrus peel, Herbstreith&Fox) was dissolved in Milli-Q water at 70°C to obtain a 4% (w/v) solution. GPTMS (Alfa Aesar) crosslinker was added to the pectin solution at a concentration of 3.68% v/v to improve its stability in aqueous media. The resulting solution was poured into cylindrical molds (13 mm diameter x 10 mm height) and cooled at -20°C overnight to induce a phase separation. Then, the samples were freeze-dried at -60°C for 48 h to obtain porous matrices. The swelling degree (SD) of the pectin scaffolds (n = 3) was evaluated in Milli-Q water at 37°C at predefined time points for 24h. At each time point the SD was calculated as eq: (Ws-W0)/W0, where W0 and Ws are the weight of the dry and swollen sample, respectively. All samples were subsequently dried at room conditions for 48 h, and the final dry weight (Wf) was measured to estimate the dissolution percentage (D) as eq: (W0-Wf/W0). Mechanical properties of the pectin samples (n = 3) were assessed by uniaxial compressive tests conducted with a Z005 Zwick/Roell testing machine equipped with a 100 N load cell at strain rate of 0.01 s⁻¹. To prevent the specimen disruption, a 30% maximum deformation was applied. The samples were fully swollen before the mechanical test in Milli-Q water at 37°C.

RESULTS & DISCUSSION: Porous scaffolds were obtained by crosslinking pectin with GPTMS. The SD of pectin scaffolds reached the plateau of 361 ± 47% after 1h. The D of the samples after swelling experiments was 5.5 ± 0.4 %. The compressive modulus of pectin scaffolds was evaluated as the slope of the linear region of the stress-strain curve. The compressive modulus was 1.4 ± 0.3MPa.

CONCLUSIONS: A novel crosslinking method for obtaining porous pectin-based scaffolds is here shown. Based on the presented results, the proposed structures could be used as scaffolds with mechanical, swelling and degradation cues for tissue engineering applications. Further experiments are currently taking place to investigate the morphology of the scaffolds. Moreover, the porosity and mechanical properties of the scaffolds will be modulated by changing pectin and GPTMS concentrations. Finally, cell experiments will be carried out in order to evaluate the cytocompatibility of the proposed chemically crosslinked scaffolds.

INTRODUCTION: In idiopathic pulmonary fibrosis (IPF) there is a massive build-up of extracellular matrix (ECM) causing a pathological remodeling of the lung with a progressive decline in lung function. We aim to describe how alterations in the tissues biomechanical properties and the composition of the ECM directs cellular responses in IPF.

METHODS: Human lung samples from healthy and IPF donors were decellularized to generate acellular scaffolds (350µm). The tissue was examined for density, stiffness and protein composition using mass spectrometry. Scaffolds, mounted on holders, were repopulated with healthy primary human fibroblasts and cultured up to 9 days. Using SILAC culture medium and mass spectrometry, the protein composition of newly synthesized heavy cellular proteins in relation to light scaffold proteins were analyzed. The organization and localization of proteins were examined with histology.

RESULTS & DISCUSSION: IPF scaffolds demonstrated an increased tissue density (2.6-fold increase p<0.01) and stiffness (2.4-fold increase, p<0.01) in comparison to healthy scaffolds. Several ECM proteins were differentially expressed between IPF and healthy derived scaffolds, which was also seen in newly synthesized proteins from fibroblasts cultured on IPF or on healthy scaffolds. Repopulated IPF scaffolds showed tendencies towards an increased production of collagen type VII, an anchoring fibril collagen, giving rise to structural alterations. Additionally, the expression of collagen type VII was visualized with antibody labeling. Production of agrin and Wnt-11 were decreased in IPF scaffolds, proteins that are associated with Wnt/β-catenin signaling, a pathway linked to IPF pathology.

DISCUSSION: We show that changes in composition and structural properties have strong impact on cellular responses. Collagen type VII is specifically involved in cell-ECM interaction. Agrin and Wnt-11 are involved in mechano-transduction pathways, which we are now further investigating with RNA analysis. Studying ECM-alterations in healthy and IPF lung tissue revealed important biomechanical and regenerative properties that can be used in the development of new therapeutic treatments.

INTRODUCTION: Articular cartilage tissue lacks the ability to self-repair, thus there is need to explore new bio-approaches for its regeneration. This work aimed to develop a mesenchymal stromal cell (MSC) and human articular chondrocyte (hACH) co-culture for cartilage regeneration, utilizing an innovative 3D thermo-sensitive chitosan (CH)-based hydrogel, ionically cross-linked with β–glycerophosphate (BGP). The direct-contact co-culture system aimed to facilitate cell–cell interactions through surface receptors and enhance the transduction of the molecular signals coordinating chondrogenic differentiation.

METHODS: CH (3.6%w/v) was dissolved in 5 ml of 0.2 M HCl and BGP (1.1g dissolved in 2.2 ml of PBS) was added to obtain a 2.5%w/v final solution for the gelification. Hydrogels were characterised physico-chemically, morpholo-gically (ESEM) and mechanically. The cytocompatibility of an MSC-laden hydrogel was assessed with a Live/Dead assay. Immunofluorescence of collagen type II and CD44 expression, and a histological study on GAGs (AlcianBlue) and collagen (SiriusRed) production were carried out for up to 28 days on the co-culture of hACH spheroids on a MSC-laden hydrogel (A) and three controls: MSC spheroids on a MSC-laden hydrogel in chondrogenic media (B) or in chondrocyte growth media (C), and hACHs spheroid on an acellular hydrogel (D).

RESULTS & DISCUSSION: The sol/gel transition of the fabricated CH/BGP hydrogel occurred at 31-33°C within 5±1 minutes. A compressive and equilibrium Young’s modulus were 37±4 kPa and 17.0±0.8 kPa respectively. ESEM images showed excellent porous structures with pore diameters < 30µm, suitable for cells attachment and nutrients diffusion. Finally, the cytocompatibility was demonstrated, as was the influence of hACH spheroids on new cartilage-like tissue formation.

CONCLUSIONS: The fabricated hydrogels presented fast sol/gel transition time that allowed to encapsulate MSCs, while their intrinsic porous structure and high uptake capability were vital for cell maintenance. This formulation offered a new and valuable platform for co-culturing cells and spheroids in close proximity, and the interactions between MSCs and hACHs resulted in enhanced chondrogenesis and cartilage production.

INTRODUCTION: Animal derived sera are associated to high batch-to-batch variations and potential contaminations and are nevertheless frequently used in cell culture. In vitro engineered adipose tissue is still highly needed to replace lost, damaged or burned subcutaneous soft tissue. Additionally adipose tissue test systems could serve to analyze (patho)physiological processes or screen for potential drugs. In the current approach, we aimed to develop serum-free, defined media for the adipogenic differentiation of human adipose-derived stem cells (hASCs), the maintenance of mature adipocytes and the co-culture of adipocytes and microvascular endothelial cells (mvECs).

METHODS: HASCs were differentiated to mature adipocytes based on a developed defined medium for 14 days. Consecutive, adipocytes were maintained in a defined maturation medium up to day 42. Adipocyte functionality was evaluated by the release of leptin and glycerol, the expression of perilipin A and the incorporation of lipids. Additionally, adipocytes were co-cultured with mvECs in a defined co-culture medium. Next to the expression of CD31 and von Willebrand factor, the functional uptake of acetylated low density lipoprotein was analyzed for the mvECs. Vascular structure formation was evaluated quantitatively.

RESULTS & DISCUSSION: The chemically defined medium led to an efficient adipogenic differentiation of hASCs with 80% compared to serum containing controls. Even after the consecutive long-term maturation till day 42, adipocytes’ cell-specific characteristics were preserved. On top, the co-culture medium facilitated the combined culture of adipocytes and mvECs until day 42 including the formation and maintenance of vascular-like structures.

CONCLUSIONS: Efficient in vitro generation of mature adipocytes out of hASCs based on defined differentiation and maturation media was implemented for the first time. This represents a fundamental achievement for the future application of in vitro adipose tissue in regenerative medicine. Additionally the transfer of the results to other approaches will be of great value for the tissue engineering branch in general.

Figure 1: Immunofluorescence staining of defined differentiated adipocytes on day 14 (A) day 42 (B) and in defined co-culture with mvECs on day42 (C), perilipin A in green, CD31 in red, cell nuclei in blue (DAPI), scale bar = 200µm.

**INTRODUCTION:** Stem cells endowed with skeletogenic potentials seeded in specific scaffolds are considered attractive tissue engineering strategies for treating large bone defects. In the context of cranio-facial bone, mesenchymal stromal/stem cells derived from the dental pulp (DPSCs) have demonstrated significant osteogenic properties. Their neural crest embryonic origin further makes them a potential accessible therapeutic tool to repair cranio-facial bone. The stem cell’s direct involvement in the repair process versus a paracrine effect is however still discussed. In addition, the best cell culture conditions for maximizing the in vivo DPSC osteogenic potential have to be established.

**METHODS:** To clarify these questions, we have followed and compared the fate of fluorescent murine DPSCs derived from PN3 Wnt1-CRE-Rosa^Tomato mouse molar (T-mDPSCs) cultured under normoxia and 5% hypoxia during the repair process of calvaria bone defects. Two symmetrical critical defects created on each parietal region were filled with either i) dense collagen scaffolds seeded with T-mDPSCs cultured under hypoxia, ii) dense collagen scaffolds seeded with T-mDPSCs cultured under normoxia iii) non cellularized scaffolds, or iv) no scaffold. Mice were imaged over a 3-month period by microcomputer tomography to evaluate the extent of repair and by bi-photonic microscopy to track T-mDPSCs. Histological and immunocytochemical analyses were performed in parallel to characterize the nature of the repaired tissue.

**RESULTS & DISCUSSION:** We show that depending on culture conditions (normoxia vs hypoxia): 1) T-mDPSCs are able to survive in the healing defect up to 3 months after implantation and 2) the mechanisms underlying the observed bone repair process are dependent on the DPSC culture conditions before implantation.

**CONCLUSIONS:** Altogether these observations are important for designing efficient therapeutic tissue engineering strategies for the treatment of large craniofacial bone defects. Further work should now focus on dissecting the signaling mechanisms underlying the mDPSCs fate choice upon implantation as well as the molecular dialogue initiated with the host cells.

INTRODUCTION: Angiogenesis, the formation of capillaries from pre-existing blood vessels, is a fundamental physiological process in health and disease and key in tissue engineering. Insufficient blood vessel formation is implicated in a wide variety of diseases with devastating consequences such as myocardial infarction and stroke. Within the tooth, precursor cells with mesenchymal stem cell properties can be found, such as dental pulp stem cells (DPSC) and stem cells from the apical papilla (SCAP). Previously, our research group demonstrated their angiogenic potential in vitro and in the ‘chicken chorioallantoic membrane (CAM) assay [1, 2]. The purpose of this study is to investigate whether DPSC and SCAP are able to establish functional blood vessel formation and blood flow in the mouse matrigel model and to identify the host-induced angiogenic pathways involved.

METHODS: Firefly luciferase (fluc) and the fluorescent protein GFP was stably overexpressed in both DPSC and SCAP by lentiviral transduction. Gelatin sponges loaded with matrigel alone or matrigel containing 1 x 10⁶ fluc⁺ DPSCs or fluc⁺ SCAPs were subcutaneously injected into nude mice. 7, 14 and 28 days xenografts were harvested for qPCR. Survival of transplanted cells was evaluated 7, 14 and 28 days after transplantation using bioluminescence imaging (BLI). Blood flow in the transplants was measured with arterial spin labeling (ASL) MRI. At the final time point of 28 days, samples were processed for ultrastructural analysis.

RESULTS & DISCUSSION: DPSC and SCAP showed remained viability and persistent after transplantation as confirmed with BLI. ASL MRI indicated an increased blood flow in gelatine sponges of both stem cell types compared to control sponges on 28 days but not 7 or 14 days after transplantation. This was supported by an increased number of blood vessels in the electron microscopy samples as well as increased mouse CD31 gene expression. qPCR analysis showed elevated levels of mouse angiogenic genes such as Ang-1 and VEGF on 14 and 28 days after transplantation in all constructs loaded with stem cells compared to controls. Increased levels of human CD31 was not observed, indicating DPSC and SCAP do not transform into endothelial cells but attract host endothelial cells to induce functional blood vessel formation.

CONCLUSIONS: Both DPSC as well as SCAP induce angiogenesis in a paracrine fashion, suggesting that they have a high therapeutic potential in pathologies correlated with inadequate angiogenesis such as stroke, myocardial infarction and chronic wounds.

INTRODUCTION: Bio-ceramic foams, as wollastonite/diopside (W/D), are obtained from preceramic polymers containing micro-sized filler powders. This process presents limited processing temperature and microstructural homogeneity, resulting in foams that mimic porous internal structure of human cancellous bone [1]. Recent discovery of short peptides able to communicate with the biological environment are opening new avenues toward the manufacture of osteoinductive materials. We demonstrated that a nona-peptide (HVP) derived from Vitronectin sequence is able to enhance human osteoblast adhesion through an osteoblast-specific mechanism [2]. In this study, polymer-derived silicate foams were covalently and selectively functionalized with a retro-inverted dimeric analogue of HVP (D2HVP) designed to increase ionic interactions with cellular Glico-Amino-Glycans (GAGs) avoiding enzymatic degradation of HVP peptide in serum-containing media [3]. Bioceramic scaffolds were then embedded with an ionic-complementary self-assembly peptide (SAP), EAK, to promote cell viability on foam-scaffolds’ surface. Moreover, W/D scaffolds were functionalized with EAK bonded to a pro-angiogenic sequence G7TIM (mapped on Timosine-ß4). In vitro and in vivo bioassays were carried out on differently functionalized W/D foams.

METHODS: W/D foams were prepared as reported in Fiocco et al. [1]. W/D was selectively and covalently functionalized with D2HVP, and treated with 0.15% w/v EAK solution, or 0.15% w/v EAK enriched with 5×10⁻⁵M of EAKG7TIM. Primary h-osteoblasts were used for in vitro bioassays. In vivo assays were performed inserting samples/controls under-skin in a murine model.

RESULTS & DISCUSSION: A compressive strength test revealed no significant decrease in foams’ mechanical properties after functionalization treatment. In vitro results confirmed the absence of cytotoxicity at 4 and 6 days. D2HVP functionalized foams gave a dramatic proliferation increase (more than 15 times) at 6 days in respect to the controls (silanized foams and W/D functionalized with a non-adhesive peptide) and enhanced mRNA specific transcript levels coding IBSP, VTN, RUNX2 and SPP1 at 2 days. In vivo bioassays proved that all functionalized foams were able to stimulate the process of ectopic mineralization, whilst silanized foams (control) didn’t develop any degree of mineralization. W/D functionalized with D2HVP, EAK and EAKG7TIM showed higher Md.S/Po.S (mineralized surface/pores surface) and greater vascularization, with a higher number of blood vessels within the individual pores.

CONCLUSIONS: The synergistic effect between bioceramic structure/composition and specific covalent conjugation of a protease-resistant osteoblast-specific adhesive peptide, combined with the properties of SAPs and their ability to deliver bioactive molecules as pro-angiogenic sequences, represents a potentially useful approach for the production of a next generation scaffold for bone tissue engineering.

INTRODUCTION: Endochondral ossification (EO) has been discussed as a promising strategy for bone defect regeneration [1]. We have shown previously that a soft collagen-based biomaterial with a channel-like pore architecture was able to induce EO in vivo [2]. Here, we present the development of a mechano-hybrid scaffold (MHS) [3] that overcomes contradictory requirements for mechanical stiffness on the cell vs. the tissue length-scale by the incorporation of a 3D-printed support structure.

METHODS: MHS were produced by: 1. Design of the support structure; 2. Production by selective laser sintering; 3. Immersion of the support structure into the collagen dispersion, unidirectional freezing and freeze-drying; 4. Crosslinking and sterilization of the MHS. Mechanical compression tests and structural characterization (SEM and second harmonic imaging [SHI]) were performed. Migration of mesenchymal stromal cells (MSCs) into the material was analyzed and the formation of extracellular matrix (fibronectin collagen-I) by fibroblasts was studied time-dependently.

RESULTS & DISCUSSION: SEM and SHI showed that the incorporation of the support structure had no effect on pore size distribution and pore alignment of the collagen guiding structure. The stiffness of the MHS was controlled by the support structure that could be varied between 1.8±0.2MPa and 12.5±1.1MPa by design modification at constant porosity. By incorporating the support structure the scaffold stiffness increased by more than 3 orders of magnitude (from low kPa for collagen to MPa-range for MHS). While no differences in MSC migration into the materials were observed, in vitro culture revealed that the support structure stabilized the collagen pore walls against cell-induced deformation leading to an aligned cell and ECM-network.

CONCLUSIONS: MHS are a novel multi-scale approach in which mechanical characteristics can be tuned independently at the micro-scale (cell-level) and the macro-scale (tissue-level). Furthermore, MHS allow to extend the principle of scaffold-guided endochondral ossification towards large animal models and thus represent a promising strategy for a translation into the clinical settings.

The field of tissue engineering and regenerative medicine has grown exponentially over the past three decades. Through developments in bioprinting, optogenetics, and the encouraging advancements in biomaterials and various other new technologies, the progressions in the field continue to make a positive impact in clinical applications and patient outcomes, as well as the overall reshaping of modern healthcare. Tissue Engineering is proudly celebrating its 25th year in publication in 2019 and would like to highlight and celebrate the many advancements and achievements of the field and the journal during this talk. With every major milestone publication year, the Journal Editorial Office strives to publish the most significant research in the field as a tribute to the TERMIS and tissue engineering community. We will present the vast achievements the field has successfully executed, as well as talk to new and exciting advances including the importance of specific research that will be highlighted in upcoming special issues. Please join us in celebrating the impact, growth, and future of the field. Tissue Engineering is the official journal of TERMIS and is proud to share this milestone anniversary with all TERMIS members and leadership.
Screening extracellular matrix environments by quantifying matrix deformations and cellular forces around angiogenic sprouts

INTRODUCTION: Cellular force generation is underlying angiogenesis, the process of growing new blood vessels, and is mediated by both chemical and physical (mechanical) cues. We report here on a three-dimensional (3D) live invasion assay utilizing natural collagen and synthetic polyethylene glycol (PEG) matrices to characterize the relationship between cellular traction-induced deformations and extracellular matrix (ECM)-properties during angiogenic invasion. These workflows allow for a mechanical characterization of the angiogenic response to different extracellular microenvironments as a tool for biomaterial screening and disease modeling.

METHODS: Human umbilical vein endothelial cells (HUVECs) were cultured in a monolayer on substrates containing 200 nm fluorescent fiducial markers for live imaging of matrix deformations in 3D. Up to 2.5 hour time lapse confocal fluorescence microscopy imaging was performed after 24 hours of invasion and image stacks were registered to quantify 3D deformations. Angiogenic invasion was quantified in 3D across substrates with varying adhesion ligand binding, stiffness and degradability.

RESULTS & DISCUSSION: Maximum collagen deformations were of the order of 2 to 10 microns. Spatial analyses of displacement fields around in vitro sprouts show displacement maxima near sprout tips and bases. Computer simulations allow estimating sprout forces, based on calculated displacements and elastic properties. Sprout protrusions exert local forces of the order of 20 nN. Displacements vary depending on substrate properties. Stiffness dependent invasion in PEG is found to be further modulated by ligand binding and degradability.

CONCLUSIONS: Our methods quantify displacements and cellular forces around angiogenic sprouts. Our analyses can help in characterizing the mechanical component of the angiogenic response to varying microenvironments allowing for a material screening technique.

INTRODUCTION: Noninvasive imaging techniques have taken precedence over other analysis techniques and this has increased the amount of data considerably. Macrophage response to biomaterial surface morphology and surface chemistry can be better analyzed from images, since other measurable biochemical tests might show a smaller response to the macrophage stress conditions. Under prolonged interaction of a macrophage with a given biomaterial, an analysis of macrophages conducted using imaging techniques may exhibit stressful condition associated with shape change at a faster rate (in time), whereas the chemical response that is acquired using other sensors may continue to be the same [1]. The quantifiable chemical response such as MTT tests, or electrochemical measurements may be less sensitive to the amount of the cytotoxicity of the biomaterial.

METHODS: Medical image analyses rely on tedious preprocessing, image enhancement, and morphological segmentation. In this work, band pass filters, Notch filters, Gabor filters and texture analysis were used and their performance was evaluated based on the type of the input image. Different conditions included: i) patterned surfaces with different groove sizes (2 μm, 20 μm) comparable to the macrophage size, ii) unpatterned surface, iii) clustered macrophages, iv) non-clustered macrophages, v) macrophages with high variance in size and shape, and vi) different macrophage density per unit area. When the macrophages have parameters with a small variance a single algorithm can be employed, whereas in cases where the macrophages have high variance more steps are needed.

RESULTS & DISCUSSION: Different parameters of macrophages were analyzed using the techniques mentioned above. Notch filters proved to be very effective to remove the effect of the micropatterned surfaces on the images. Gabor filters were carefully adjusted to select macrophages with different spatial extents, and the selectivity in the orientation allowed to neglect features that resulted from spurious noise and objects that represented cellular debris. The texture analysis could distinguish macrophages that were affected by the cytotoxicity of the environment (where cytoplasm collapsed around the nucleus) from the unaffected ones (cytoplasm was distinct).

CONCLUSIONS: Different macrophage conditions such as size, shape, macrophage density and host surface morphology were analyzed. Due to different parameters used on the algorithm, further analysis is required in order to make the algorithm fully automated.

Evaluating the effect of acidic microenvironment on human induced pluripotent stem cells-derived cardiomyocytes
A. Ferrini 1,4, L. Zwi-Dantsis 1, N. Rosenthal 4,5, M.M. Stevens 1,2,3

INTRODUCTION: One of major events occurring after a myocardial infarction is an acidification of the tissue, with the pH dropping to 6.5-6.8, due to the switch from aerobic metabolism to anaerobic glycolysis. It has been reported that cardiac differentiation of murine embryonic stem cells is strongly inhibited by extracellular acidic pH 1; however, the effects of pH on cardiac differentiation of human induced pluripotent stem cells (hiPSCs) remain to be investigated. The aim of this study was to assess the effects of low pH on cardiac differentiation of hiPSCs and on differentiated hiPSC-Cardiomyocytes (CMs) in terms of cell viability, CMs yield and gene expression profile. Four pH values were tested: control (pH 7.7), pH 6.8 (value of the ischemic myocardium), pH 7.1 (intermediate between acidic and physiologic) and pH 7.4 (standard recommendation for cell culture).

RESULTS & DISCUSSION: Results from MTT assay and LIVE/DEAD® staining showed that pH 6.8 significantly reduces hiPSC-CMs metabolic activity and viability during differentiation, respectively. The CMs yield quantified by flow cytometry analysis at day 21 was 83.8 ± 1.3% in the control, while it was halved at pH 6.8. Next, gene expression analysis showed a significant down-regulation of cardiac-specific markers in the cells cultured in acidic pH. The same results were confirmed when the pH was lowered at later timepoints, on beating hiPSC-CMs. Finally, we demonstrated that Insulin like Growth Factor-1 (IGF-1) is able to rescue the low pH phenotype, and by adding IGF-1 at concentrations of 10 and 50 ng/mL the yield and viability of the CMs cultured in pH 6.8 were increased back to the control values.

CONCLUSIONS: Taken together, these findings demonstrate that acidic pH significantly affects cardiac differentiation of hiPSCs and already differentiated hiPSC-CMs. A better understanding of the sensitivity of these cells to the acidic ischemic microenvironment is crucial when considering their potential delivery for cardiac repair purposes. Moreover, we showed that the pro-survival growth factor IGF-1 is able to protect the cells from the acidic pH, making it a good candidate for the encapsulation in biomaterial strategies for cell therapy.

INTRODUCTION: Biomimetic collagen and nanohydroxyapatite (coll-nHA) scaffolds enhance bone repair in small defects. However, large defects require the incorporation of additional biomolecules. Having previously identified c-Jun N-terminal kinase 3 (JNK3) as a mechanically-activated modulator of the superior osteogenic potential of MSCs derived from children in comparison to adults. Our aim was to design a therapeutic nanomedicine able to facilitate the intracellular activation of JNK3, and incorporate this into a coll-nHA (coll-JNK3*free) scaffold to recapitulate the extraordinary regenerative potential of children in adults.

METHODS: A JNK3 activator (JNK3*) was made by complexing a JNK3 activator mini-peptide with in-house nHA nanoparticles (NPs), previously used for miRNA delivery. Effects of JNK3* on the metabolic activity and the osteogenic potential of C-MSCs (10-11y) and A-MSCs (20-30y) were evaluated. JNK3* was then, incorporated into the 3D collagen-nHA delivery platform (coll-JNK3* scaffold) and effects were assessed in vitro and in vivo.

RESULTS AND DISCUSSION: No toxic effects of the JNK3* doses (0-5 µM) were observed in either C-MSCs or A-MSCs. When treated with the 5 µM dose, JNK3* uptake reached 90% in C-MSCs and 88% in A-MSCs, and promoted osteogenesis in A-MSCs toward the superior levels previously observed in non-treated C-MSCs. When JNK3* was incorporated into the coll-nHA -coll-JNK3*- the nanomedicine was taken up by A-MSCs as early as day 3 and their osteogenic capacity was significantly increased. When this coll-JNK3* activated scaffold was implanted for two weeks in critical-sized rat calvarial defects, the infiltration of host cells positive for MSC markers CD44, CD105, and CD90 was observed, as was the upregulation of pathways associated with osteogenesis and angiogenesis. Furthermore, significantly enhanced bone volume fraction and histological analysis proved accelerated bone healing in coll-JNK3* treated defects compared to JNK3*free scaffolds or untreated empty defects as early as 4 weeks post-implantation.

CONCLUSIONS: We have successfully developed an off-the-shelf 3D-scaffold-based therapeutic delivery platform, which enhances the osteogenic capacity of MSCs by facilitating JNK3 activation, ultimately showing we can recapitulate children’s regenerative capacity and accelerate bone repair in adults.

INTRODUCTION: The amniotic membrane (AM) is considered to be an ideal means for clinical applications due to providing a substantial source of stem cells alongside with having great scaffold-like characteristics including biocompatibility, low immunogenicity, anti-inflammatory and anti-microbial effects [1], [2]. Simvastatin, a previously well-known in vitro osteogenic factor, has been recently shown to induce osteogenesis and vasculogenesis in vivo concurrently [3]. In the present study, we conducted an in vitro experiment investigating the in situ osteogenic differentiation of the amnion cells cultured in an osteogenic medium and compared the results with a control medium.

METHODS: Human placentas were collected after cesarian sections and the AM was removed by blunt dissection. After being washed by PBS, biopsies were made and placed in 12 well plates containing Control Medium or Osteogenic Medium. The Control Medium comprised of a combination of traditionally used osteogenic regulators consisting of Dexamethasone, vitD3, Ascorbic acid and beta-Glycerophosphate. In the Osteogenic Medium, BMP9 and/or Simvastatin, two molecules which we previously hypothesized to have synergistic osteogenic properties, were added as treatment group. The medium was changed every other day. In order to study the effects of the medium, we measured the amounts of osteogenic specific genes and proteins as well as cell viability. We also evaluated Calcium content as an indicator of late phase mineralization.

RESULTS & DISCUSSION: The results showed that simvastatin and BMP-9 have a noticeable impact on expression of osteogenic specific genes and proteins. The synergistically effects of simvastatin and BMP-9 make them an appropriate candidate for differentiation of stem cells.

CONCLUSIONS: We presented here promising results of a new protocol of in situ osteogenic differentiation of amniotic cells by simvastatin and BMP-9 with possible applications in the clinic.

INTRODUCTION: Skeletal muscle injuries often result in an incomplete regeneration due to the formation of a fibrotic scar tissue [1]. In this work, we evaluated the suitability of different ELR-based hydrogels for the healing of a volumetric muscle loss (VML) defect in rats.

METHODS: ELRs were recombinantly biosynthesized and chemically modified (if needed) as previously described [2]. A VML rat model was used to study the healing of tibialis anterior (TA) skeletal muscles with ELR-based hydrogels. A total of 19 adult male Wistar rats (n = 38 TAs) were randomized in four groups: untreated control (n = 11), biodegradable chemically crosslinked ELR hydrogel (n = 11), biodegradable physically crosslinked SELR hydrogel (n = 11) and no injury control (n = 5). TA muscles were harvested after 2 and 5 weeks and studied through histology (H&E, Picrosirius Red for collagen) and immunofluorescence (anti-M1 (CCR7) and M2 (CD206) macrophages).

RESULTS & DISCUSSION: H&E stained slices showed no significant differences among groups in a gross view, with all the samples showing almost full muscle repair. However, when studied thoroughly, we found a difference in the density and size of the newly formed myofibers, being the ELR-treated samples more similar to the healthy ones, suggesting a better muscle healing. Furthermore, collagen content increased from 2 to 5 weeks in the non-treated samples and those treated with the physical ELR hydrogel (p < 0.05), which is characteristic of fibrotic non-functional tissue. Finally, the samples obtained from animals treated with both ELR-based hydrogels showed a higher content of M2 macrophages than the non-treated control at 2 weeks (p > 0.001), which indicates that the initial inflammatory response may resolve more beneficially, also suggesting a better muscle healing with the use of the ELR-based hydrogels.

CONCLUSIONS: Overall, these results suggest the potential beneficial effect of biodegradable ELR-based hydrogels in muscle healing, which implies a great advance in the field. Further studies should focus in the assessment of the regeneration of skeletal muscle in larger animal models, where a more critical defect can be created and other methods can be used to evaluate the functional recovery of skeletal muscle.

INTRODUCTION: Gene-activated scaffolds (GAS) offer promising wound healing therapeutic capabilities by functional activation of infiltrated cells at the implant site [1]. Using our self-derived pro-angiogenic GAS composed of the gene stromal-derived factor-1α (SDF-1α) loaded onto collagen scaffolds (SDF-1α GAS), we sought to investigate the therapeutic effects on wound healing cells (endothelial, Schwann and adipose-derived stem cells; healthy and diabetic).

METHODS: A collagen-GAG scaffold was soak-loaded with polyethyleneimine-SDF-1α plasmid polyplex (N/P 10) to develop SDF-1α GAS. Experiments were performed by seeding either 1) human umbilical vein endothelial cells (HUVECs) 2) human Schwann cells (SCs) 3) human adipose-derived stem cells (ADSCs). qRT-PCR and immunofluorescence was conducted at days 7 and 14. Specifically, a VE-cadherin (soluble) ELISA and an angiogenesis proteome profiler were employed to monitor endothelial growth and secretion of angiogenic factors in HUVECs and ADSCs respectively. Cultures on gene-free scaffolds were used as control.

RESULTS & DISCUSSION: In HUVECs, SDF-1α GAS significantly suppressed the release of soluble junctional adhesion molecule, VE-cadherin at day 7 (p<0.05) and 10 (p<0.0005). Immunoreactivity also showed a significantly (p<0.05) high expression for VE-cadherin at day 14. In SCs, SDF-1α GAS induced transient activation of SDF-1α, VEGF-A and CXCR7 at both mRNA and protein level. SCs on SDF-1α GAS displayed significantly high, early expression of functional receptor p75NGFR (p<0.0005) and pro-neurogenic laminin (p<0.005). ADSCs (healthy and diabetic) also showed similar activation of SDF-1α, VEGF-A and CXCR7 as that of SCs. ADSCs on SDF-1α GAS displayed strong anti-fibrotic response (~2x) with significantly (p<0.005) low deposition of collagen VI by day 7.

CONCLUSIONS: Overall, SDF-1α GAS displayed enhanced therapeutic effects by (1) preserving endothelial integrity in morphogenic HUVECs, by (2) enhancing the differentiation of SCs towards a functional phenotype and by (3) inducing an early anti-fibrotic response in both healthy and diabetic ADSCs.

INTRODUCTION: Thick tissue engineering constructs produced by layering of cell sheets suffer from poor gas and nutrient exchange and consequently fail1. In this study, we report a facile method to produce viable thick cell sheet constructs using poly (L-lactic acid) (PLLA) fibrous membrane interlayer between MC3T3-E1 cell sheets.

METHODS: PLLA membranes approximately in 150±20 µm thickness were obtained by using an electro spinning set-up. Then, MC3T3-E1 cell sheets were obtained via Nunc UpCell™. The multilayered structures were formed by laminating two cell sheets onto one PLLA membrane and a final constructs were composed of a total of 3 PLLA membranes and 4 cell sheets. There was no PLLA membrane implemented in the construction of control group. All constructs were characterized in terms of cell viability and cell death while ALP activity, collagen synthesis and sGAG quantity were examined only in PLLA/cell sheet construct.

RESULTS & DISCUSSION: The superior viability of multilayered structures containing PLLA membranes was demonstrated during the culture period. Three-dimensional tissue conjugates consisting of cell-biomaterial combinations, which can be transferred in a practical manner and have a wet state thickness of 1 mm, were achieved. According to the results of cell viability by Alamar blue assay, the PLLA/cell sheet structures were observed to survive and proliferate during culture. However, the control group exhibited a decreased cell viability during the same culture period. Lactate Dehydrogenase (LDH) analysis confirmed the acute cell death in the control group. Increased sulfated glycosaminoglycan (sGAG) and collagen synthesis was recorded in the multilayered constructs. In addition, the success of the survival rate of the constructs was verified with live/dead staining.

CONCLUSIONS: A porous nanofiber membrane interlayer used in the fabrication of cell sheet constructs of this study yielded a thick and viable product with enhanced transport, mechanical and handling characteristics.

3D bioprinting of hydrogel constructs with microchannels and vasculature

INTRODUCTION: Despite the recent progress in 3D bioprinting custom cell-laden structures, it is still challenging to engineer well-defined and interconnected vasculature into hydrogels. Conventional bioprinting processes (e.g., printing lattice structure) usually compromise the printability because of the inadequate gelation of bioinks during layer-by-layer deposition. Here we introduce a non-porous approach to fabricate 3D hydrogel constructs with tubular porosity to potentially construct vasculature.

MATERIALS & METHODS: Gelatin is used as printable and sacrificial bioink due to its reversible thermo-sensitivity. Gelatin methacryloyl (GelMA) is used as a matrix bioink after photo-crosslinking. Gelatin and GelMA are simultaneously printed side-by-side for each layer, creating a relatively flat surface for the next layer deposition. We hypothesize that this method enhances the printability of the matrix bioink and enables the pre-loading of endothelial cells during printing.

RESULTS & DISCUSSION: Though viscous bioinks are usually used, in the conventional bioprinting process it is still easy to encounter a fusion of layers and thus poor porosity features on the side. Our approach benefits from the structural support obtained when printing two (potentially more) bioinks side-by-side. There is no concern for layer fusion and the tubular lumen can be generated after removing one of the bioinks. To engineer vascular tissues, endothelial cells are commonly post-seeded into the lumen area which is very likely to result in poor seeding efficiency and homogeneity, especially when dealing with complicated 3D channel networks. The presented approach herein enables the encapsulation and migration of viable endothelial cells in the sacrificial phase and thus the formation of an endothelial monolayer during culturing. Furthermore, this approach could be used to fabricate perfusable hydrogel constructs, with the potential for engineering thick tissue.

CONCLUSIONS: We developed a versatile 3D bioprinting approach to fabricate cellularized vascular constructs in one-pot without the need of post cell seeding. The method enables good printability of constructs with tubular porosity and in situ endothelization.

INTRODUCTION: Chemotherapeutic resistance is a topical question in longstanding treatment of cancer. Therefore, deciphering the basis of chemotherapeutic resistance of cancer cells has evident significance. The cellular response of cancer cells is pre-dominantly modulated by different cell types present in tumor-associated stroma and extra-cellular matrix \cite{1, 2}. At the time of metastasis, cancer cells involve in remodeling the extra-cellular matrix; results in change in pore sizes, interconnectivity and stiffness of cancer stroma \cite{3}. Hence, the critical role of individual cells and extra-cellular matrix in resistance of chemotherapeutics needs to be unwound. Mesenchymal stem cells are actively recruited by tumor-associated stroma \cite{4}. Herein, we venture to explore the influence of human adipose derived stem cells (hASCs) on therapeutic response of human osteosarcoma (Saos 2) within 3D extra cellular environment created using silk fibroin and gellan gum.

METHODS: Silk fibroin – gellan gum based hydrogels with tunable mechanical properties were prepared by varying the blending ratio of gellan gum (GG) to silk to regulate the formation of spheroids of Saos 2 in presence of hASCs in an engineered 3D osteosarcoma model. The proliferation of cells within the spheroids was assessed by Alamar blue assay. For chemotherapeutic response studies, the spheroids were exposed to different dilutions of doxorubicin for 24 h and the viability of cells after treatment was assessed by MTT assay. The morphologies of both cells were examined under confocal and scanning electron microscopies.

RESULTS & DISCUSSION: The highest rates of cell proliferation, spheroid formation and collagen secretion were observed in less stiff hydrogels. It was also identified that the blending of silk with gellan gum enhanced cell survival and functionality possibly owing to biocompatibility of natural silk fibroin. When cultured in equal seeding ratio and treated with the model chemotherapeutic agent such as doxorubicin, the heterotypic culture exhibited different sensitivity compared to homotypic spheroid.

CONCLUSIONS: The heterogeneity of the present model at structural and cellular level, recapitulates more closely the dynamic characteristics of physiological tumor stroma. This is anticipated to be useful in predicting the efficacy of cancer chemotherapeutics.

Innovation in amniotic epithelial cell-based tendon regenerative protocols
Presenting Author: Barbara Barboni, bbarboni@unite.it
Unit of Basic and Applied Bioscience, Faculty of Bioscience and Agro-Food and Environmental Technology, University of Teramo, Via Renato Balzarini 1, 64100 Teramo, Italy

INTRODUCTION:
Amniotic epithelial cells (AEC) have demonstrated to stimulate healing after transplantation in experimental and spontaneous tendon defects [1]. The present research has been designed to assess whether the amplification protocols are able to enhance AEC -based tendon regenerative potential. To this aim, AEC amplified under standardized (CTR) [2], progesterone (P4) [2], and teno-inductive conditions (PRE-DIFF) [3] were compared (Tab. 1). Tendon regeneration was analyzed at d14 and d28 by evaluating AEC ability to promote damage resolution by sparing inflammation-induced healing moieties and encouraging ECM repair.

METHODS:
A tendon defect of 5mm³ in diameter was induced in rams to avoid any endogenous P4 influence. Lesions were filled with fibrin glue in SHAM (n=20) or with fibrin glue plus 5 x 10⁶ CTR (n=20), P4 (n=20) and PRE-DIFF (n=20) amplified AEC (passage III). Tendon microarchitecture was analyzed in explants with hematoxylin-eosin and Herovici and ECM remodeling using immunohistochemistry (IHC) in order to detect von Willebrand Factor and COL 3 and 1. Tendon inflammation was assessed through the IL 12/IL 10 ratio by RT-qPCR.

RESULTS & DISCUSSION:
The injured SHAM tendons showed a still disorganized ECM at d14 displaying scattered COL 3 fibers, hypercellularity and a high vascular density. On the contrary, AEC transplanted tendon revealed clear signs of resolution. In particular, transplantation of P4 and PRE-DIFF cells lead to a mature and organized ECM displaying aligned COL 1 fibers and blood microvessels sustained by a lower IL12/IL10 ratio (p<0.05 vs CTR and p<0.001 vs SHAM). Tissue regeneration further improved in AEC groups at d28. However, the more advanced tissue recovery was observed in PRE-DIFF group. In this case, a significant increase in COL 1 fiber density, a complete alignment of ECM fibers and vessels were recorded in combination with the lowest IL12/IL10 ratio (p<0.05 vs both CTR and P4).

CONCLUSIONS:
For the first time, it has been demonstrated that phenotype has to be considered in order to potentiate AEC tendon regenerative influences. P4 or tenogenic-pre-commitment AEC have showed, indeed, to better encourage early ECM deposition (d14), both by blunting tendon pro-inflammatory phase. PRE-DIFF maintained this anti-inflammatory mediated regenerative ability even at d28 when a complete ECM remodeling was surprisingly observed in the defect area. The present results confirmed the powerful tendon regenerative potential of AEC by pointing towards advanced in vitro protocols insights as a good strategy to improve and standardize AEC-tendon based therapy.

INTRODUCTION: Polymeric microspheres (MS) thanks to their high surface area can be used as substrates for cell culture both in static and dynamic conditions [1]. Moreover, they can be assembled to produce cell-material constructs according to "bottom-up" tissue engineering approach. The drawback of MS is their hydrophobicity and lack of cell-adhesive molecules on the surface. In this study, we propose to develop poly(L-lactide-co-glycolide) (PLGA) MS and modified their surface by adsorption of collagen type I (COL) or poly(L-lysine) (PLL) in order to promote cell adhesion and growth.

METHODS: MS were obtained with emulsification oil-in-water method. 7.5% PLGA (85:15, Mn=100 kDa, Mw=210 kDa) solution in DCM was added to 1% PVA, stirred (1000 rpm) and left for 24 h for DCM evaporation. Formed MS were vacuum filtered, washed, dried and sieved to collect particles with diameter 50-100 µm. 20 mg MS were incubated in 0.1 M NaOH for 30 min, washed 3x in UHQ-water to activate PLGA surface and coated with COL (40 µg/ml, 10 h) or PLL (0.01%, 10 h). MC3T3 osteoblast-like cells were cultured with MS for 14 days in three media: α-MEM, osteogenic medium (α-MEM with 0.05% ascorbic acid and 0.05% β-glycero-phosphate) and osteoclast conditioned medium. Cell adhesion, proliferation, viability and morphology were tested.

RESULTS & DISCUSSION: Emulsification method allowed us to obtain MS with regular shape and size for cell culture. The presence of PLL and COL coatings improved cell adhesion on day 1 in all studied media. The cells were better spread on PLL- and COL-modified MS when compared to non-modified PLGA MS.

CONCLUSIONS: The obtained results show that PLL and COL coatings on PLGA MS improved cell adhesion and growth of MC3T3 cells in all studied media.

INTRODUCTION: The use of patient-derived induced pluripotent stem cells (iPSCs) for disease modelling increased our knowledge of disease processes and offers fascinating perspectives for personalized therapy. The globally increased demand for patient-derived iPSCs has created an urgent need for standardized and automated production processes. To that end, we developed the StemCellFactory, an integrated system for automated reprogramming and expansion of iPSCs for disease modeling and drug screening.

RESULTS & DISCUSSION: On the StemCellFactory platform, we automated reprogramming of human dermal fibroblasts, clonal selection and expansion of primary iPSC clones, and scaled enzyme-free sub-cultivation of iPSC lines. The platform contains various devices, including incubators, liquid handling units, storage places, analytical devices and robots for transportation and handling of materials. For process control, we developed a novel software tool that controls all processes executed by the StemCellFactory and computes on-line acquired metrology data of iPSC cultures for automated decision making, like confluency cell morphology, and turbidity. Management for every device is implemented, comprising data tracking and two-stage error handling. Automated management of resources, disposables and liquids avoids support shortages and guarantees constant production conditions.

OUTLOOK: Within the scope of further enhancing the system towards the generation of state-of-the-art iPSC models, we have devised an implementation plan for the automated genome editing by CRISPR/Cas technology. Furthermore, hardware and software extensions for the generation of iPSC from blood samples were implemented.

CONCLUSIONS: We developed an automated platform and novel software tools that address the technological challenges for automation of complex stem cell culture processes. This includes automated CRISPR/Cas-based genome editing of iPSCs. We expect the StemCellFactory platform to meet the challenges of the increasing demand for patient-derived iPSCs and their derivatives.

ACKNOWLEDGEMENTS: The project "StemCellFactory III" is funded by the European Regional Development Fund (ERDF) under grant number EFRE-0800972.
Microfibrillated silk to make strong yet degradable biomaterials

INTRODUCTION: The production of silk nanofibers using traditional methods (eg. electrospinning) requires the silk to be dissolved before forming nanofibers. This process destroys the hierarchical structure of silk fibroin that imparts its exceptional mechanical properties. Regenerated nanofibers also have much faster biodegradation rate. We have pioneered the production of silk nanofibers, referred to here as microfibrillated silk (MFS), directly from silk fibres using mild chemicals and mechanical exfoliation. The process is easily scalable and can be manipulated to control fibre aspect ratio. Here we report the use of MFS as free standing scaffolds or as reinforcing fillers for hydrogel 3D printing.

METHODS: Degummed silk fibres from Phiosomia ricini silkworms were fibrillated using a combination of milling and homogenisation under alkaline conditions. MFS suspensions were either cast directly to form nonwoven scaffolds or combined with chitosan solution and printed to form MFS reinforced hydrogel scaffolds. The resulting materials were characterised (chemical and mechanical properties, morphology) and tested for cytocompatibility using human derived fibroblasts and HaCaT keratinocytes.

RESULTS & DISCUSSION: The addition of MFS significantly improved the shape fidelity and compressive strength of 3D printed chitosan hydrogel scaffolds without affecting fibroblast attachment and proliferation. By controlling the silk degumming, milling and homogenisation steps, MFS with fibre diameters under 500 nm were produced. These fibre based constructs were able to support the growth and proliferation of fibroblasts and HaCaT keratinocytes. Scaffold degradation testing is ongoing and will be discussed.

CONCLUSIONS: The development of MFS enabled the production of silk biomaterials with superior mechanical properties, as the structural component of the material and as a filler/bulking agent. The flexibility of the process will enable the development of a range of fibre reinforced composite biomaterials.

INTRODUCTION: Glaucoma, vascular and ischemic malfunctions, and trauma result in severe damage to optical nerves and may lead to blindness. Currently there is no treatment option for such conditions. In this study, we aimed to develop a novel decellularization protocol to produce optical nerve grafts. The ECM composition and in vitro cytotoxicity characterizations are reported.

METHODS: The optic nerve segments were isolated from bovine eyes. A decellularization protocol, modified version of a previously suggested method for sciatic nerves, was established and conducted [1]. Several protocols were compared. Tissues were agitated in distilled water for 7 h and rinsed in PBS for 72 h in all groups.

In order to investigate the effectiveness of the proposed protocols and to understand the extent of matrix protection levels, collagen and glycosaminoglycan (GAG) content were analyzed. in vitro degradation and swelling tests were performed. The cell removal capacity of each protocol was studied by routine histology and transmission electron microscopy (SEM).

RESULTS & DISCUSSION: The H&E staining studies showed enhanced preservation of scaffold integrity in all groups (Figure 1 A-G). There were no cell nuclei observed in tissues after DAPI stainings (Figure 1 H-N). Analyses revealed a 28.11 mg/mg collagen content in native optic nerves while these values were calculated as 17.72, 10.32, 9.28, 14.21, 15.85, and 9.27 for decellularization groups of 1 to 6, respectively. There was a significant difference (p < 0.001) in collagen content per mg tissue among the control and decellularization groups. Additionally, decellularized tissues showed semi-transparent appearance.

CONCLUSIONS: A suitable method was developed as a result of thorough comparisons. The proposed decellularization protocol may pave the way for prospective studies towards novel approaches in the treatment of optic nerves.

INTRODUCTION: In the recent years, microfluidic systems have shown to be a powerful tool for recreating tissue- and organ-like functions by different approaches, providing basis for developing preclinical assays with improved predictive power [1]. The development of new drugs is increasingly expensive, time-consuming while only a few compounds can reach the market fulfilling all safety and efficacy criteria. Evaluating potential drug candidates at early stages of the preclinical process became essential by finding new technologies. Microfluidic culture platforms conjoining human microtissues in a physiological-like arrangement could provide a translational solution [2]. Starting with assay relevant a few organs, Human-on-a-chip platforms aim to combine more than ten organs to mimic the healthy and diseased physiology with patient specific engineered tissues to create the Patient-on-a-chip. This allows to create personalized medicine solutions for diseases and evaluate drug responses with the patient’s specific genetic background [3].

METHODS: In multi-organ-chip (MOC) platform integrated with an on-chip micro-pump, we established thirteen different organ equivalents combined into twelve different co-culture platforms interconnecting two to four organs.

RESULTS & DISCUSSION: We showed that in MOC we can study physiologically relevant organ crosstalk, induce and study diseases such as Diabetes type II, lung cancer and Absorption, Distribution, Metabolism, Excretion and Toxicity (ADMET) of compounds [4-6] and will present our latest advancements on the MOC platform.

CONCLUSIONS: The microphysiological systems create new opportunities and solutions to drug discovery dilemma at the preclinical phase as well as bringing new challenges up [7]. Advancements in tissue engineering field to create patient specific physiologically relevant combination of organ models with advanced microfluidic platforms to mimic the responses of different genetic backgrounds and emulate human biology at the preclinical phase would substantially improve prediction of drug safety and efficacy.

INTRODUCTION: The development of complex in vitro cell-based models and advanced tools that enable their characterization are of utmost importance for drug screening and disease modeling. Current in vitro cell-based models for cardiotoxicity assessment rely on homotypical cardiomyocyte cultures, which do not resemble the complexity of the human cardiac environment. The aim of this study was to develop a physiologically relevant in vitro cardiac microtissue, using human-induced pluripotent stem cell (hiPSC) that better recapitulates the human heart microenvironment features and allows the prediction of potential cardiotoxic effects.

METHODS: A novel 3D hiPSC-derived tri-culture cardiac microtissue was developed by combining aggregates of hiPSC-derived cardiomyocytes (hiPSC-CM) with hiPSC-derived endothelial cells and mesenchymal cells (hiPSC-EC+MC) inside alginate microcapsules that were cultured in dynamic conditions for up to 2 weeks. A toolbox of analytical techniques, including quantitative MS-based proteomics, was implemented to unveil the molecular crosstalk involved in the communication between the different cell types and their impact on hiPSC-CM maturation.

RESULTS & DISCUSSION: The tri-culture microencapsulation strategy was successfully implemented showing maintenance of cell viability, metabolic activity and cellular phenotype up to 15 days of culture. Particularly, characterization of the cardiac microtissue showed evidences of structural maturation of hiPSC-CM when compared to hiPSC-CM mono-cultures. For further depiction of the communication between the different cell types co-cultures of hiPSC-CM and hiPSC-EC were established also showing evidences of structural maturation of the hiPSC-CM in co-culture. Evaluation of hiPSC-CM functionality by calcium imaging showed similar calcium handling properties of hiPSC-CM in both mono and co-culture, although some differences were observed in response to drugs, namely to norepinephrine. More importantly, quantitative whole proteomic analysis revealed increased expression of: (i) ratios of morphological cardiac maturation-related proteins (MYH7/MYH6, MYL2/MYL7, TNNI3/TNNI1); and (ii) extracellular matrix proteins, namely collagens I, III, fibronectin and other soluble proteins, which may be responsible for the communication between both cell types.

CONCLUSIONS: Overall, this study provides insights towards the establishment of biologically-relevant in vitro cardiac tissue models. Additionally, the characterization methods herein implemented were demonstrated to have an essential role in in vitro cardiac preclinical research for the understanding of in vivo microenvironment recapitulation.

INTRODUCTION: Polymers are widely used biomaterials for tissue engineering applications due to having tailorable properties, however, they need modifications to improve their limited interaction with biological tissues. Two key points were aimed in this study. First, manufacturing of multiscale porous scaffolds, made of photocurable polymer, by combining techniques of emulsion templating and 3D printing. Secondly, decorating these scaffolds with in vitro generated ECM to increase their biological performances.

METHODS: Scaffolds, made of high internal phase emulsion (HIPE) of methacrylated PCL, were created via additive manufacturing. MLO-A5s were cultured on scaffolds for 4-weeks. Cellular activity, mineral and collagen deposition assays were performed. Cell penetration depth was assessed by histology images. Microarchitecture of scaffolds and cell attachment were observed under SEM. After decellularisation, to confirm the efficiency of the process, DNA content was measured. Both plain and hybrid scaffolds were recellularisated by using human embryonic stem cells-derived mesenchymal progenitors (hES-MPs) and compared. Finally, chick allantoic membrane (CAM) assay was used to explore the angiogenic potential of the scaffolds.

RESULTS & DISCUSSION: Multiscale porous scaffolds were obtained successfully. ECM matrix composed of mineral and collagen was deposited on scaffolds and then 95% of DNA was removed (decellularisation). In recellularisation process, cells not only showed higher attachment on ECM decorated scaffolds but also exhibited significantly higher increase in cellular activity and cell infiltration. Additionally, CAM assay showed that the presence of ECM on scaffolds resulted in higher angiogenic potential in comparison with plain scaffolds.

CONCLUSIONS: 3D printed PCL polymerized HIPE scaffolds support cell adhesion, proliferation and migration and it is a promising candidate to fulfill the requirements of defect-matching bone grafts. Additionally, our in-vitro generated ECM decorated polymer system proposed an applicable approach to improving bioactivity and angiogenesis of polymer scaffolds to encourage precursors to differentiate mature bone.

INTRODUCTION: Previous studies have elucidated the possible role of fetal tissue in scar-less healing. Our study takes one-step forward and makes use of bioreactor expended human fetal mesenchymal stem cell (FMSC) to produce MSC secretion (HFS). We employ poly (lactic-co-glycolic acid) (PLGA) particle as a slow release capsule and prove the promoting effect of HFS encapsulated PLGA (HEP) particle on the healing of diabetic skin wound which is considered as refractory skin defect in clinical scenario.

METHOD: FMSC were seeded on collagen-coated polystyrene microcarrier in the ratio of one million cells/30g carriers in a commercially available bioreactor (PBS, USA). Upon collection of HFS, cultures were incubated with serum-free medium for 24hrs. Collected condition medium was filtered with 70μm cell strainer (Falcon) and removed the cell debris by centrifugation. The supernatant was subjected to lyophilization. HFS was reconstituted in the concentration of 100ng/mL. Alamar blue (Invitrogen) was used to test cell viability. Scratch assay and co-culture insertion (BD Bioscience) was used to test cell migration ability. Furthermore, fibroblast populated collagen lattice (FPCL) model and organotypic keratinocyte-fibroblast co-culture (OKC) system were used to test the effect of HEP in vitro. For in vivo study, we employed streptozotocin-induced diabetes model in rat and created a full thickness defect on rat back skin.

RESULTS & DISCUSSION: FMSCs were mixed with microcarriers and cultured under stirring within bioreactor for 14 days. Alamar blue test showed that 50ng/mL HFS maintained human fibroblast and keratinocyte viability (n=3, p<0.05). HFS also promoted cell migration of the two types of cells after treatment for 3 days (n=3, p<0.05). Simultaneously, HFS prohibited FPCL contraction and promoted keratinocyte differentiation in OKC model after 7 days treatment (n=3, p<0.05). Then HFS was encapsulated in PLGA particle by double emulation method. BCA test showed that in vitro release of proteins of HEP could sustain at lease for 1 week. ELSA data showed that HFS contains PDGF-BB. The promoting effect has also been observed on the diabetic rat model (n=6, p<0.05). HFS also contains long non-coding RNA H19 that may contribute to regulate skin healing.

CONCLUSIONS: In summary, HEP may slow release encapsulated HFS to promote skin defect healing in the diabetic rat model. PDGF-BB and H19 may contribute to the promoting effects of HFS on skin healing.

¹University of Mons, Research Institute for Biosciences, Biology of Marine Organisms and Biomimetics Unit, 23 Place du Parc, 7000 Mons, Belgium ²University of Innsbruck, Institute of Zoology and Center of Molecular Bioscience Innsbruck, Technikerstr. 25, 6020 Innsbruck, Austria

INTRODUCTION: Biological glues are a promising source of inspiration for biomedical applications. Many temporary attaching animals, like flatworms and sea stars, rely on a duo-gland adhesive system, where adhesive glands secrete the proteinaceous glue and a different gland type produces a de-adhesive substance [1]. We aim to identify and characterize these secretions, in order to provide templates for biomimetic approaches.

METHODS: To understand the molecular and morphological basis of biological adhesion, we used a large toolbox combining molecular biology and histological methods. We combined proteomics, RNA-seq, in situ hybridization, RNAi, lectins, immunohistochemistry, histological staining, transmission- and scanning electron microscopy.

RESULTS & DISCUSSION: The simplest temporary adhesive system can be found in the marine flatworm Macrostomum lignano. We showed that the attachment of M. lignano relies on the secretion of two large adhesive proteins, Mlig-ap1 (5,407 aa) and Mlig-ap2 (14,794 aa) [2]. In Mlig-ap1 several known protein-carbohydrate and protein-protein interaction domains are present. Furthermore, Mlig-ap1 is characterized by lysine- and arginine-rich repeats, rendering regions of this protein extremely positively-charged. Mlig-2 is glycosylated and contains two von Willebrand factor domains, two trypsin inhibitor-like domains, a low density-lipoprotein receptor domain, and multiple thrombospondin type-1 repeats. Based on RNAi knockdown experiments, we propose that Mlig-ap2 attaches to the substrate and Mlig-ap1 exhibits a cohesive function [2].

The adhesive secretion of sea stars shares many characteristics to that of flatworms. In Asterias rubens, one protein was characterized and named sea star footprint protein -1 (Sfp1) [3]. Sfp1 resembles Mlig-ap1 in many aspects including the unusual large size, similar protein domains and carbohydrate binding sites. In A. rubens, 22 additional proteins were identified in adhesive secretions and at least two were found to be glycosylated.

CONCLUSIONS: Our findings indicate that temporary bioadhesion is based on the interaction of adhesive and cohesive proteins. Cohesive proteins share a large size and certain functional domains, while glycosylation is prevalent in adhesive proteins. Characterization of the adhesive proteins in flatworms and sea stars may inspire the development of new biomimetic adhesives.

INTRODUCTION: Dysregulation of miRNAs, notably miR155 [1], has been associated with disc degenerative disease (DDD) [2]. The relevance of unprotected miRNAs for therapeutic applications suffers from their fast in vivo degradation. Thus, the development of nanocarriers is a prerequisite for miRNA therapeutic use. Lipid nanocapsules (LNCs) offer a suitable strategy thanks to their ability to encapsulate nucleic acid [3]. The purpose of this work was to formulate and fully characterize innovative miR155-LNC for a potential use in DDD treatment.

METHODS: miR-155-LNCs were formulated by phase inversion process. After purification, miR155-LNCs were fully characterized (size, polydispersity index (PDI), zeta potential). Encapsulation efficiency (EE) and drug loading (DL) were assessed by Quant-IT-dye® quantification. miRNA-155 release and enzymatic protection were investigated by dialysis and gel electrophoresis. miR-155-LNC's internalization and impact on cell viability in human adipose stromal cells (hASC) were assessed by confocal/FACS analysis and MTT assay, respectively.

RESULTS & DISCUSSION: miR155-LNCs exhibit a diameter of 75.0 ± 1.3 nm, a PDI of 0.06 ± 0.03 and a positive zeta potential. EE and DL were estimated to 75.2 ± 1.2% and 59.0 ± 9.3µg/g of LNC respectively. miR155 sustained release from LNCs was observed (23.3 ± 7.1% compared to 94.8 ± 5.4% for unencapsulated miR-155, after 4 h). miRNA-endonuclease protection by LNC was confirmed by electrophoresis. After 24h of incubation with fluorescent miR155-LNCs, hASC viability was of 71.66% ± 4.23% for 5,9 ng/mL of miRNA, a recommended concentration for efficient cell transfection. Internalization of miR-155-LNCs in hASC cells was also demonstrated.

CONCLUSIONS: LNCs could be a promising approach to protect, release and transfect therapeutic miRNA. Further experiments (in vitro and in vivo) will be needed to confirm the interest of this nanoplatfor to vectorize new therapeutic in order to counteract DDD.

INTRODUCTION: The influence of the manufacturing process of xenogenic biomaterials on their biological performance remains incompletely understood in terms of bone regeneration [1]. Calcium-phosphate-based (CaP) materials have received a lot of attention due to their chemical similarity to bone, but also due to their excellent biocompatibility [2-3]. The primary objective of this study was to analyze the in vivo biological performance (new bone formation and osteoconductivity) of experimental bovine hydroxyapatites (BHA) sintered at different temperature. The secondary objective was to correlate the in vivo results with the physicochemical and topographical characteristics of the studied biomaterials.

METHODS: Protein-free hydroxyapatite from bovine origin was produced under sub-critical conditions and then either briefly hardened at mid-range temperature (820ºC), or sintered at 1200ºC. The physicochemical properties were assessed by scanning electronic microscopy (SEM), measurement of surface specific area (BET) and X-ray diffractometry (XRD). The materials were then implanted in standardized alveolar bone defects in minipigs. Histological and histomorphometric evaluations (% of newly formed bone and % of bone-to-material contact) were performed using non-decalcified sections.

RESULTS & DISCUSSION: Marked topographical differences were observed by SEM analysis, showing highly structured surfaces on the unheated and hardened BHAs, while the highly sintered one was characterized by a much smoother surface and very few remaining porosities. In vivo samples showed a similar regenerated area observed in the 3 groups, while the highly sintered BHA presented a significantly lower percentage of newly formed bone than the unheated one (p=0.009). In addition, the percentage of bone-to-material contact (osteoconductivity) was significantly lowered by sintering when compared to the unheated (p=0.01;) and to the hardened (p=0.02) groups.

CONCLUSIONS: Sintering of BHA at 1200ºC has a marked effect on its physicochemical characteristics as described already on the literature. However, its biological performance is significantly lowered in the present study. By contrast, mid-range sintering temperature such as 820ºC preserves surface roughness and microporosity, and allows good bone regeneration and osteoconductivity with no statistically significant differences compared with the non-sintered BHA. Clinicians must take into account that the process of biomaterial manufacturing can significantly influence the quality of bone regeneration, when choosing the biomaterial for their regenerative procedures.

ACKNOWLEDGEMENTS: The co-authors France Lambert, Eric Rompen and Geoffrey Lecloux are integrating members of the Wishbone SA board.

Group of Cell Physiology and Cellular Engineering, Zürich University of Applied Sciences, Wädenswil, Switzerland

INTRODUCTION: Tissue engineering aims at the generation of biological constructs to heal or replace damaged tissues and organs. Tissue engineering also includes the use of tissues to study complex 3D biological models, and to test the pharmacology and the toxicity of experimental medicines. In this work, we show that primary human cells, which are essential building blocks of functional biological tissues, can be modified efficiently and stably with constitutive or conditional reporter genes to measure precisely specific cellular conditions (e.g. vitality, cellular stress, activity of intra-cellular pathways).

METHODS: Various reporter gene architectures sharing a common human secreted embryonic alkaline phosphase (hSEAP) cDNA under the transcriptional control of different human promotors were tested in primary human fibroblasts, primary human keratinocytes and HaCaT. In addition to the hSEAP cDNA and the promotor sequence, some reporter gene architectures were made conditional by including an antioxidant responsive element (ARE) motif that is a target of the Nrf2/KEAP1 pathway [1]. The activity of the reporter gene is determined by measuring the concentration of hSEAP secreted in the cell culture medium.

RESULTS & DISCUSSION: First, promotors play a pivotal role in the activity of reporter genes and the activity of the promotors strongly depend on the cellular environment. Interestingly, the ARE motif does not function with all promotors and has no effect in specific conditional reporter gene architectures. Finally, the ability of the ARE motif to modulate the activity of conditional reporter gene architecture is strongly dependent on the cell type.

CONCLUSIONS: Collectively, these data show that the choice of regulatory elements is critical for the proper function of reporter genes, especially when working with primary cells. Nevertheless, specific constitutive or conditional reporter gene architectures can work efficiently in primary human cells. Primary human cells containing such reporter gene architectures could be used to generate innovative reporter tissues or organs.

ACKNOWLEDGEMENTS: Financial support was received from the Zürich University of Applied Sciences.

INTRODUCTION: Accumulating evidence has been revealing the importance of the sensory nervous system in the orchestration of bone turnover and repair [1]. The aim of this work is to develop a cell-free and growth-factor free hydrogel capable to promote neurotization and angiogenesis in a bone regeneration context.

METHODS: Hydrogels were produced using Elastin-like polypeptides (ELP) and different ratios of poly(ethylene glycol) (PEG), and the laminin-derived adhesion peptide IKVAV (or its scrambled VKAIV): ELP + (PEG); ELP + [low adhesion peptide] and ELP + [high adhesion peptide] and characterized by rheology, porosity and enzymatic degradation. Primary rat cell cultures: mesenchymal stromal cells (MSCs), endothelial cells (ECs) and sensory neurons (SNs) had metabolic activity, cellular behaviour and/or gene expression evaluated. Best in vitro performance composition was implanted subcutaneously in mice and the vascularization and innervation potential were assessed by histology and immunohistochemistry.

RESULTS & DISCUSSION: The [high IKVAV] composition had an important performance in vitro inducing: (i) upregulation of a panel of osteogenic markers in MSCs; (ii) upregulation of important molecules that trigger angiogenesis process in ECs; and (iii) the formation of the longest neurites in SNs. In vivo, hydrogels induced no signals of major inflammation. The surrounding region of the [high IKVAV] composition had higher vessel density relative to the scrambled after 26 days and the innervation process was detected only in IKVAV composition implantation for both time points. The density and surface of neuronal structures seem to increase over time.

CONCLUSIONS: We produced ELP-based hydrogels with fine-tunable rheological properties, porous structure and biocompatible in vitro. [high IKVAV] composition showed higher osteogenic, angiogenic and neurotization potential in vitro. In vivo, hydrogels were not inflammatory and [high IKVAV] composition induced higher vascularization and neurotization subcutaneously. [High IKVAV] composition has important features for biomedical applications, being a cell- and growth factors-free composite able to support vascularization and neurotization in vitro and in vivo with a great potential to induce osteogenesis.

INTRODUCTION: Mesenchymal stromal cells (MSCs) exert numerous therapeutic effects including immunomodulatory and anti-inflammatory effects in vitro and in vivo. These therapeutic effects can be attributed in part to the paracrine action and soluble factors released, including extracellular vesicles (EVs). Size exclusion chromatography (SEC) has recently been demonstrated as an effective alternative to differential ultracentrifugation (UC) for the isolation of EVs [1-3]. Herein, we assessed the isolation of EVs by SEC from MSCs that were culture-expanded from primary CD362+ human umbilical cord stromal cells.

METHODS: EVs were isolated from human umbilical cord CD362+ MSC conditioned media by UF and SEC. Size and particle count of eluted SEC fractions were determined using nanoparticle tracking analysis (NTA) and transmission electron microscopy (TEM). Identification and characterisation of EVs was achieved by SDS-Page and using flow cytometric analysis (MACSplex human exosome detection kit, Miltenyi).

RESULTS & DISCUSSION: EVs were identified primarily within the first four SEC eluted fractions. Within these, mode and mean particle size were 87.7nm and 142.7nm respectively ± 68.5nm. Average particle yield was 6.89 x 10^3/cell. Detection of the EV marker CD63 in elution fractions corresponded with low protein concentration. Additional EV markers CD9, CD63 and Alix were detected by western blotting. Flow cytometric analysis determined the surface expression phenotype of MSC derived EVs shared several phenotypic MSC markers, specifically CD29, CD44, CD73, CD105, CD142, CD146 and MCSP were all detected.

CONCLUSIONS: The results demonstrate SEC to be an appropriate and efficient method of isolating EVs from human umbilical MSC. Furthermore, the preliminary flow cytometric surface phenotyping of EVs from CD362+ human umbilical cord MSC is a novel finding.

INTRODUCTION: MSC paracrine activity, including both soluble molecules and factors released within extracellular vesicles (EVs), can be modulated by cues from the microenvironment, mimicking the milieu established during an injury event as the one generated by a bone fracture [1]. Although several cell-secreted factors have been identified, their exact role in some aspects of the fracture healing process, i.e. in angiogenesis, is currently unknown. Given that the presence of areas of hypoxia is a prominent feature of various inflamed and diseased tissues, we here aim to determine the role of the injury microenvironment in modulating the angiogenic potential of MSC secretome fractions.

METHODS: Human MSCs were obtained from liposuction aspirates of subcutaneous adipose tissue. When MSCs reached 80% confluence, they were incubated for 24 hours with the inflammatory factors TNF-α (50 ng/ml) and IL1-α (50 ng/ml), either under normoxic or hypoxic conditions. The angiogenic potential of total conditioned media (CM), corresponding EVs, and EV-free CM were evaluated in vitro by analyzing their effect on HUVEC migration, proliferation and differentiation. Additional ex vivo metatarsal assay was performed to confirm in vitro results.

RESULTS & DISCUSSION: Preconditioning of MSCs under mentioned stimuli triggered the cell secretory activity and these stimulated factors affected the angiogenic process in different ways. We observed that while the secretomes stimulated under hypoxic conditions enhanced in vitro endothelial cell migration, the combinatorial effect of inflammatory factors and hypoxia significantly increased their differentiation capacity without affecting their proliferative potential. In order to confirm in vitro results, we investigated the sprouting of endothelial cells by ex vivo metatarsal assay and a widespread sprouting of blood vessels from fetal bone was induced by secretomes derived under hypoxic conditions and combination of inflammatory factors.

CONCLUSIONS: Our preliminary results confirm the importance of a proper pre-conditioning to positively influence the cell paracrine activity. Additional analysis of the secretomes and a deep characterization of the role exerted by EVs would be crucial in the generation of successful clinical cell-free therapies.

INTRODUCTION: Scaffold geometry and architecture are key attributes to affect cell adhesion, tissue ingrowth and cell differentiation processes of human mesenchymal stromal cells (hMSCs). A defined scaffold geometry, fiber thickness well below 10 µm and mesh size can be achieved through melt electrowriting (MEW) that combines electrospinning of a polymer melt with computer-assisted moving of the collector [1]. Due to the low fiber diameter, such scaffolds, even when produced from PCL, remain soft and flexible. Additionally, the complex micro-environment of the extracellular matrix (ECM) is crucial to control stem cell differentiation. Individual ECM components like laminin (LN) and fibronectin (FN) are commercially available but cannot reproduce the positive effects of the complex native ECM without a proper 3D arrangement. The aim of this project is to generate a functionalized 3D fiber scaffold to enhance the remodeling and repair of adipose tissue in vitro by combining the 3D construct design with the adipose-inductive DAT (decellularized adipose tissue). Thereby, the DAT-functionality should reduce the need for artificial differentiation reagents in the cell culture medium.

METHODS: Box-structured poly(ε-caprolactone) (PCL) fiber scaffolds were fabricated with MEW and afterwards functionalized by the adsorption of DAT, FN or LN. The adipogenic differentiation behavior of hMSCs cultivated on these scaffolds and induced by the short-time application with differentiation factors in the culture medium was examined by quantitative RT-PCR and ELISA. Intracellular lipid droplets were visualized via immunofluorescence staining and quantified via triglyceride assay.

RESULTS & DISCUSSION: Adipogenic differentiation of hMSCs on functionalized (DAT, LN, FN) as well as non-functionalized scaffolds differed depending on the pre-differentiation time as detected by adipogenic mRNA, intracellular FABP4 protein, and leptin secretion. Especially, the DAT-functionalization enhanced the adipogenic outcome of short-time pre-differentiated hMSCs. Moreover, the accumulation of adipocyte-specific lipid droplets increased with extended incubation in adipogenic media and higher complexity of the fiber functionalization.

CONCLUSIONS: The beneficial impact of fiber functionality on the differentiation of hMSCs into the adipogenic lineage was proven. Even the short-time pre-differentiation of hMSCs was sufficient to achieve adipogenesis on the 3D scaffolds while the adipogenic outcome was further enhanced by the DAT-functionality. Scaffolds with a defined architecture produced by MEW combined with DAT are a promising tool to further investigate the influence on adipogenic hMSC differentiation.

INTRODUCTION: Dermal papilla (DP) cells are key hair inductive cells. However, the isolation of inductive human DP cells is still very challenging. Our previous studies demonstrated that their indirect culture with epidermal cells with stem-like characteristics (EpSCs) improved DP cells phenotype, and their combined injection recreated hair follicle-like structures in the nude mice [1]. Nonetheless, this approach is limited by the required large numbers of cells. To surpass that, this work hypothesizes that EpSCs conditioned medium (CM) promotes similar beneficial effects in DP cells.

METHODS: EpSCs were selected out of a mixture of human skin-derived keratinocytes by culturing them in a 3T3-feeder layer. After being removed from the feeders, EpSCs were culture in KSFM and 48h-CM was collected and used on DP cells. After 5 days of culture in CM, DP cells were characterized regarding their proliferation (DNA quantification), glycosaminoglycans and protein (GAGs) production (Bradford, Sirius Red and DMB assays), inductivity (ALP activity) and secretome (ELISA). Moreover, cells cultured with CM were used to prepare spheroids, a 3D-system known to partially recover DP phenotype [2], and further cultured in standard DMEM to confirm the stability of the phenotype achieved in 2D-culture.

RESULTS & DISCUSSION: DP cells proliferation and ALP activity were significantly higher when DP cells were cultured with EpSCs CM, however the production of protein and GAGs decreased. Regarding the release of growth factors, DP cells cultured in CM secreted higher levels of VEGF, BMP2, IL-6 and lower levels of PDFG-AA. When aggregated in spheroids, DP cells from the CM culture behaved more closely to the native ones, proliferating less and producing higher quantity of proteins, while sustaining higher ALP activity. These cells also showed increased ALP and sustained α-SMA and versican V1 expression.

CONCLUSIONS: Our results suggest that EpSCs CM can beneficially modulate DP cellular behavior and phenotype. Further studies are being performed to confirm these results in vivo.

INTRODUCTION: Acellular ECM-based biomaterials are obtained at the cost of a significant loss of critical components of the innate matrisome, which will impair the bioactivity of the end product. In the frame of the BIOCAPAN project (www.biocapan.eu), a novel water-based, detergent-free method was developed to generate ECM-based biomaterials from the human pancreas, to be used to enhance islet function and prolong their lifespan.

METHODS: Human pancreases were benchmarked to obtain 1 cm³ cubes pancreatic tissue. Samples were placed in 1-liter jars containing deionized water and shaken at 200rpm for 24 hours at 4°C. Then, they were rinsed with DNAse and a TRIS-EDTA buffer solution containing MgCl before a final wash with deionized water for 24 hours. The so-obtained biomaterial was then frozen, lyophilized and cryomilled, to produce a fine ECM powder that was eventually solubilized with HCl-pepsin solution. The powder’s matrisome was analyzed using mass spectrometry and an ELISA-based multiplex assay. The effects of the powder on cell viability through MTT assays and cell functionality through glucose-stimulated insulin secretion were tested with multiple cell lines including human MSC and murine insulinoma cells (MIN6), and with hESC-derived pancreatic progenitors to determine their capacity to drive cell differentiation. The ECM was also tested with Jurkat Cell line for apoptosis assay, A549 cell for ROS production, hemolysis, coagulation, platelets, complement and lymphocyte activation to assess the safety profile. The immunogenicity of ECM was tested in a Treg induction assay where naïve human CD4⁺ T cells were cultured with aCD3/aCD28 Ab, IL-2, TGFβ +/- ECM.

RESULTS & DISCUSSION: Human pancreas ECM-based soluble powder can be successfully and consistently obtained with our method. The powder shows the presence of several critical components of the innate matrisome, including multiple types of collagen, which was the most abundant ECM component. A large number of ECM regulators, ECM glycoproteins, ECM affiliated proteins, proteoglycans and secreted factors were also identified. Viability of MIN6 cells cultured as a monolayer was not affected by powder addition independently of its concentration in the culture media, suggesting that the ECM powder was not toxic. MSCs proliferated and grew well in presence of our ECM which was also able to induce higher yields of hESC-derived β-cells. The pancreatic ECM did not show activation of hemolysis, coagulation, platelets or lymphocyte. Finally, ECM did not impair in vitro Treg induction, a major mechanism of immune tolerance.

CONCLUSIONS: We have developed a novel, gentler detergent-free method to produce ECM scaffolds from the human pancreas whose composition recapitulates the innate islet niche. Extensive in vitro experiments are undergoing to test the ability of these ECM-based scaffolds to enhance islet function and lifespan in vitro and in vivo.

INTRODUCTION: Within the field of Tissue Engineering, there is great need for platforms that allow high-throughput (HT) screening of cell responses to wide ranges of biomaterial formulations and environments (libraries).

METHODS: A custom microfluidic system [1] was used to produce 3D hydrogel fibers with concentration gradient of gelling polymer, ECM molecules and bioactive components. Human adipose stem cells (hASCs) were encapsulated and exposed to wide ranges of conditions within one single gradient and the most adequate formulations could be identified by measuring the best cellular outcome (Fig. 1).

RESULTS & DISCUSSION: Gellan Gum (GG) hydrogels within 0.5-1 wt.% revealed a storage modulus range of 5-20 kPa. hASCs cultured for 1 week in chondrogenic medium showed significantly increased expression of Sox9 (chondrogenic regulator) on the stiffer hydrogels as assessed by immunocytochemistry, validated through western blot. In parallel, cell-laden GG microfibers of 0.5-1 wt.% gradient in composition were produced and subjected to similar culture conditions. The Sox9 expression in each cell was tracked along the gradient position and its gradual increase was observed with the increasing GG concentration. Reversely, the adipogenic triggering (PPAR-γ expression) was favored on the softer regions, as previously validated [2]. We further employed our system to detect different stem cell responses (viability, adhesion, morphology), as function of bioactive matrices such as hyaluronic acid and gelatin.

CONCLUSIONS: We have employed a novel microfluidic system to obtain 3D gradients for HT analysis of stem cell responses, not only recapitulating those taking place in normal hydrogels but also capable of discriminating different formulations for distinct responses.

INTRODUCTION: Although oxygen levels may remain apparently stable inside a cell culture incubator, we do not know much about the relationship between the oxygen consumption rate of the cells and the diffusive delivery of oxygen through the overlying medium layer [1,2]. In the present study, we tested a new "in situ" non-invasive optical sensor foil based technique for real time monitoring of the vertical oxygen gradient formed within cell culture wells with different cell concentrations.

METHODS: Human adenocarcinomic alveolar epithelial cells (A549) were seeded at 5.0×10⁴, 1.0×10⁵, and 1.5×10⁵ cells/cm² in 48-well plates containing 1 ml of high glucose Dulbecco’s modified Eagle Medium (DMEM, Sigma-Aldrich), supplemented with 10% fetal bovine serum and 1% antibiotics. For the “in vitro” monitoring of oxygen levels, a camera-supported optical sensor foil-based technique VisiSens (PreSens, Regensburg, Germany) was employed. Sensor foils were attached to small, 3D-printed ramps with a 25 degrees angle and a maximum height of 3.3 mm. Oxygen levels were optically measured using a pixel profiling tool (48 pixels across the sensor) every hour for a period of 96 hours.

RESULTS & DISCUSSION: The experimental set up reveals that a confluent cell culture may be exposed to oxygen levels lower than required to sustain standard physiological conditions. Oxygen concentrations in high density cell cultures (1.5×10⁵ cells/cm²) dropped from 8% at 48h of culture to 2-3% after 96h, compared to a drop from 13% to 9% when cultivating 5.0×10⁴ cells/cm² during the same time frame. In both cases, oxygen concentrations near the well surface remained constant (Figure 1).

CONCLUSIONS: With this new technique, it is possible to determine how the cell density can affect the oxygen supply during cell culture. Moreover, oxygen gradients can be measured non-invasively in a kinetic way.

ACKNOWLEDGEMENTS: Financial and material support was received from PreSens. The project was support by a grant from the Bayerische Forschungsstiftung (“Happihypo”).

INTRODUCTION: Many clinical situations that require the use of biomaterials and cells combined with them hold immense potential for reversing injuries, illness or degenerative situations as they have shown promising in-vitro. However, there are many hurdles that must be drawn for their success in clinical practice (1). As far as the biomaterial itself is concerned, the specific medical application determines the design and specific parameters demanded but, in general terms, universal requirements for successful usage in the body without immune rejection could be: biocompatibility, modulable mechanical properties according to the needs or the tissue to which they are intended, stable physical and chemical properties with the biological systems (or modulable when needed), able to be functionalized and with high wear resistance or with integration capacity. About the inclusion of cells in biomaterials, they should guarantee cell survival and/or integration into the host tissue as major challenges (2). “Clickable” ELRs meet these essential requirements and have proven to be useful both in-in vitro and in-vivo for many clinical situations.

METHODS: ELRs were biosynthesized and purified with the advantage of their Inverse Temperature Cycling. All the bioproduced ELRs were systematically and fully characterized for their composition, purity, thermos-responsiveness, structure and endotoxin content. The ε-amine group in the side chain of the lysine residues were modified to bear cyclooctyne and azide groups for click-chemistry crosslinking. This chemical modification has been previously reported (3). The modified ELRs were characterized by NMR and FTIR to assess the degree of modification.

RESULTS & DISCUSSION: Structural and a biofunctionalized ELRs have been prepared and modified to bear the reactive groups needed to crosslink via “click chemistry”. The initial dynamic covalent crosslinking of this stereospecific and fast reaction combined with thermoresponsive behavior of these engineered proteins allows to obtain different “in situ” or pre-formed supports (injectable hydrogels or fibers), that can be easily modulated for their mechanical, topological and chemical properties. These ELR-based supports can preserve cell growth both in-vitro and in-vivo.

CONCLUSIONS: Our group has a series of clickable and biocompatible ELR, suitable to support or imbibe cells for various applications in tissue engineering and regenerative medicine.

ACKNOWLEDGEMENTS: This project has received funding form the European Union’s Horizon 2020 research and innovation program under grant agreement No 646075.

Hydroxyapatite/MgO spherical granules: An innovative bone substitute to prevent dental and orthopaedic infections

C.C. Coelho1,2,3,4, R. Araújo1,2, P. A. Quadros4, S. R. Sousa1,2,5, F. J. Monteiro1,2,3

Presenting Author: Catarina Coelho, catarina.coelho@i3s.up.pt

INTRODUCTION: Nowadays, there is a great demand for bone regenerative therapies [1]. However, most of the bone substitutes present in the market are not capable of preventing bacterial colonization, leading to the development of serious infections that are a major concern in dentistry and orthopaedics [2]. For that reason, this work is focused on the development of a granular bone substitute of hydroxyapatite (HAp) and magnesium oxide (MgO) to prevent implant-associated infections.

METHODS: HAp/MgO granules were produced [3] and characterized using SEM with X-ray mapping and FTIR. In vitro antibacterial activity of the granules was accessed in terms of planktonic bacteria and biofilm formation towards Staphylococcus aureus (S. aureus) and Escherichia coli (E. coli). Cytotoxicity tests were carried out in accordance to ISO 10993-5:2009 and with live/dead cell staining. For that purpose, ISO 10993-12:2012 was used as a guide to prepare granules extracts. The production of reactive oxygen species (ROS) was also evaluated.

RESULTS & DISCUSSION: HAp/MgO spherical granules were successfully produced with diameters between 0.5 and 1.0 mm. SEM images showed MgO distribution in the surface of the granules and the FTIR presented the characteristic peaks for this composite. Granules containing concentrations of MgO equal or higher than 3 wt% were able to significantly reduce S. aureus and E. coli planktonic growth and biofilm formation. Cytotoxicity assays revealed that none of the produced materials were cytotoxic to L929 fibroblasts. Additionally, no significant cell death was observed with live/dead cell staining after 3 days of incubation with granules extracts. Finally, none of the materials induced ROS formation by cells.

CONCLUSIONS: HAp/MgO granules significantly reduce both S. aureus and E. coli planktonic growth and biofilm formation, being a promising antibacterial bone substitute.

INTRODUCTION: Angiogenesis is essential for cancer cells survival and cancer progression [1]. Therefore, blocking this phenomenon is one possible route to develop more effective anticancer agents. Fucoidan seems to be a promising natural-origin alternative to current cancer chemotherapeutics, with both pro- and anti-angiogenic behavior reported [2]. To clarify this biological behavior, the angiogenic potential of an effective anticancer fucoidan extract [3] was assessed.

METHODS: Two tube formation assays (TBA) were conducted: one where fucoidan (0.5 mg ml⁻¹) was added at the time of human endothelial cells (HPMEC-ST1.6R) seeding on top of matrigel (i.e. TBA I); and another where fucoidan was only added 4h after endothelial cells adherence (i.e. TBA II). The secretion of the angiogenic factors VEGF and PDGF was quantified by ELISA. Two different Chick Embryo Chorioallantoic membrane (CAM) assays were performed: one with only fucoidan injection (i.e. CAM I) and the other with fucoidan injection after a tumor mass (MDA-MB-231) onplantation (i.e. CAM II).

RESULTS & DISCUSSION: Tube formation assays demonstrated that fucoidan inhibited (TBA I) or disrupted (TBA II) the formation of tubular-like structures. Fucoidan, although not affecting VEGF secretion, significantly reduced the expression of PDGF (70% in TBA I and 40% in TBA II). Fucoidan injection reduces the number of blood vessels (CAM I) and significantly decreased tumor size by 25% (CAM II).

CONCLUSIONS: These results demonstrate the anti-angiogenic potential of this fucoidan extract both in vitro and in vivo. Fucoidan has a two-fold anticancer therapeutic potential: having toxic effect over cancer cells and hampering tumor growth by exerting a negative effect on tumor vascularization.

Human platelet lysate-based hydrogels – A humanized 3D platform for disease modelling guided by tissue engineering
C. F. Monteiro¹, C. A. Custódio¹, J. F. Mano¹
Presenting Author: Cátia Monteiro, cfrmonteiro@ua.pt
¹Department of Chemistry, CICECO, University of Aveiro, Campus Universitário de Santiago, 3810-193 Aveiro, Portugal

INTRODUCTION: Drug discovery and development, namely anticancer therapies, including for osteosarcoma (OS), has been hindered by the shortage of complex and robust drug screening platforms. [1,2] Human methacryloyl platelet lysates (PLMA) hydrogels are herein proposed as humanized 3D platforms for tumor invasiveness modelling and drug screening. [3]

METHODS: Spheroids of human bone-marrow mesenchymal stem cells (BM-MSC) and three tumor cell lines (MG-63, SaOS-2 and A549) were formed in ultra-low attachment plates and then encapsulated into PLMA hydrogels at 10, 15 and 20% (w/v), PEG and Matrigel for 14 days. For OS model development, MG-63 spheroids encapsulated into PLMA hydrogels at 15% (w/v) were cultured alone or surrounded by BM-MSC and human osteoblasts (OB). At 14 days of culture, a 3-day doxorubicin treatment was performed. Spheroid viability, morphology, area and invasiveness were assessed.

RESULTS & DISCUSSION: PLMA hydrogels supported cell spheroid viability, sustaining an in vivo-like cell polarity and invasion of all cell types. PLMA enhanced the invasiveness ability of the different cell spheroids comparing with Matrigel, providing tunable mechanical properties that allowed the control of invasion speed. In the OS co-culture model, long tumor invasive branches and a complex network of BM-MSC were formed, and OB maintained their phenotype. Comparing to OS mono-culture model, the tumor cells in the co-culture model were less sensitive to doxorubicin treatment, reflecting the protective role of stromal cells in chemoresistance. A higher cell viability in invasive branches and non-significant changes in spheroid area also demonstrated the pivotal role of stromal cell in cell behavior and drug resistance.

CONCLUSIONS: Overall, this study provides a proof-of-concept that the proposed 3D invasion models can be used to study early tumor metastatic events and as a platform for screening and validation of therapeutic agents, as clearly demonstrated in the case-of-study herein presented based on OS modelling.

ACKNOWLEDGEMENTS: This work was supported by European Research Council grant agreement ERC-2017-PoC-789760 for project MicroBone.

INTRODUCTION: Stroke is a major global health problem with limited treatment options. Mesenchymal stem cells (MSCs) hold great potential as a regenerative therapy for stroke having previously been shown to promote repair and functional recovery in rodent models of cerebral ischaemia. As this occurs independently of cell migration to the ischaemic brain, engraftment and differentiation, focus has shifted to the paracrine actions of MSCs. MSCs secrete a vast array of chemokines, cytokines and growth factors, collectively termed the secretome. This secretome has been hypothesised to promote repair through several mechanisms including decreasing inflammation and promoting endogenous angiogenesis. The aims of our research were to assess the efficacy of the MSC-derived secretome (conditioned medium) on recovery, neuroinflammation and lesion volume in a mouse model of ischaemic stroke.

METHODS: Human bone marrow-derived MSCs were primed with 10 ng/ml human recombinant IL-1α for 5 minutes then at 24 h, conditioned medium was collected and 10x concentrated. Stroke was induced in 12-16 week old male C57BL/6 mice (Charles River Laboratories, UK) using the intraluminal filament model of middle cerebral artery occlusion. Either 400 μl 10x concentrated conditioned medium or MesenPRO (vehicle) was administered at the time of reperfusion by subcutaneous injection. Mice were then recovered for 14 days undergoing MRI scans at 48 h and a battery of behavioural tests to assess recovery. In a follow up study, treatment with conditioned medium was delayed to 24 h post-stroke.

RESULTS & DISCUSSION: MSC-derived conditioned medium at the time of stroke had a neuroprotective effect leading to ~30% reduction in lesion volume at 48 h, which was associated with modest improvements in recovery. When conditioned medium treatment was delayed to 24 h post-stroke, as expected, there were no differences in lesion volume between groups but significant improvements in recovery were observed. More specifically from day 7 onwards, conditioned medium treated mice had significantly lower 28-point neurological scores than the vehicle group and at day 8 performed better in a nest building task.

CONCLUSIONS: Our results suggest administration of MSC-derived conditioned medium at the time of stroke had a neuroprotective effect and led to modest behavioural improvements after ischaemic stroke. Delaying administration to 24 h also led to improvements in recovery and this was independent of neuroprotection. Therefore, the MSC secretome has great potential as a therapy for stroke and further work to elucidate the mechanisms of action is warranted.
Sympathetic nervous system and inflammation interplay in periprosthetic inflammation

INTRODUCTION: The chronic inflammatory response to implant-derived wear particles is the hallmark of aseptic loosening and subsequent implant failure. Periprosthetic joint inflammation is a complex local biological response that takes place on synovial membrane-like interface tissues, triggered by the implant degradation products (polymeric, ceramic, metallic particles and ions) that shed and accumulate in this tissue. Over the past decades, accumulated evidence has clearly attributed a pivotal role to the sympathetic nervous system and its neurotransmitters in regulating chronic inflammatory conditions. In rheumatoid arthritis (patients and animal models), a deprivation of neuronal derived neurotransmitters in synovium tissue, due to the loss of sympathetic innervation, has been observed [1,2,3]. In implant aseptic loosening (AL) where the chronic inflammatory response to implant-derived wear particles results in implant failure, the involvement of the sympathetic nervous system is not yet elucidated.

METHODS: In this study we evaluated the systemic and local profile of neuroimmune molecules involved in the interplay between the sympathetic nervous system and the periprosthetic inflammation in hip AL.

RESULTS & DISCUSSION: Our results showed that periprosthetic inflammation does not trigger a systemic response of the sympathetic nervous system, but is mirrored rather by the impairment of the sympathetic activity locally in the hip joint. Moreover, macrophages were identified as key players in the local regulation of inflammation by the sympathetic nervous system in a process that is implant debris-dependent and entails the reduction of both adrenergic and Neuropetide Y-ergic activity. Additionally, our results showed a downregulation of semaphorin 3A that may be part of the mechanism sustaining the periprosthetic inflammation. Overall, the local sympathetic nervous system emerges as a putative target to mitigate the inflammatory response to debris release and extending the lifespan of orthopedic implants.

INTRODUCTION: During the reconstitution, and restoration of the integrity of injured skin, scar formation is frequently observed. A way to study and understand mechanisms underlying scarring and in turn, prevent it, is to focus on the fibroblast-to-myofibroblast transition. This work proposes the development of an ECM like material, linked with TGF-β1 and TGF-β3 growth factors, to generate a 3D platform in which their role and overlapping functions in the fibroblast-to-myofibroblast transition, and consequently on healing and scaring, can be unraveled.

METHODS: Several covalent or non-covalent chemical approaches have been considered, in order to graft gellan gum hydrogel (GG) with TGF-β1 and TGF-β3, implicated in the fibrotic scarring response and the scarless healing process. The obtained modified-GG was analyzed by 1H NMR and intrinsic viscosity tests. In addition, morphological and biological characterization of human dermal fibroblast phenotype after seeding within modified-GG will be performed, coupled to the expression pattern analysis of TGF-β-related proteins.

RESULTS & DISCUSSION: The incorporation of the growth factors within the hydrogel without any chemical bonding showed that although the proteins are retained in the higher concentration polymer network, they are rapidly released into the reacting medium from less concentrated polymeric networks. The first chemical strategy based on carbodiimide chemistry, bonded the growth factors via a non-reversible reaction. The BSA-FITC protein was linked to the GG, avoiding its release, independently of the GG concentration used.

CONCLUSIONS: TGF-βs-laden hydrogels show potential to work as 3D platforms to further investigate the implication of these growth factors in the scar formation during wound healing by modulating the TGF-β1/TGF-β3 ratio.

ACKNOWLEDGEMENTS: This project has received funding from the European Research Council (ERC) under the European Union's Horizon 2020 research and innovation programme (grant agreement N° ERC-2016-CoG-726061).
A bioartificial rat heart tissue: Perfusion decellularization and characterization

INTRODUCTION: Heart-related defects are still prone to progress irreversibly, and can eventually lead to heart failure. A personalized extracellular matrix (ECM) based bioartificial heart created by allografts/xenografts can retain the original 3D architecture, in addition to preserved heart ECM. This study aimed at developing a procedure for decellularizing heart tissue harvested from rats, and evaluating decellularization efficiency in terms of residual nuclear content and structural properties.

METHODS: A modified version of a previously published [1] decellularization protocol was followed in this study. A total of 4 rat hearts (7 week-old, female Wistar Rats) were harvested, three of them were perfused as described below, and the forth served as a positive control. Briefly, rats were euthanized, and hearts were removed from the chest. A blunt needle was inserted into the ascending aorta and sutured to allow for retrograde coronary perfusion using chemical and biological agents (surfactants, acids, bases, and enzymes) combined with physical stimulation.

RESULTS & DISCUSSION: Removal of nuclear material (92.4%) was confirmed by histological examination. Tissue sections showed no or little visible cell nuclei in decellularized heart, whereas the native heart showed dense cellularity. Intact structure of decellularized heart was verified by the structure of whole heart, as well as similarity between decellularized and native cardiac muscles in terms of fiber alignment. Furthermore, no significant difference was detected between native and decellularized heart in terms of fiber diameter.

CONCLUSIONS: Our findings demonstrate that a heart bioartificial scaffold can be efficiently decellularized with chemical and biological agents, coupled with aortic perfusion as a physical stimulation. Technique described here could be used for other species upon necessary modifications. Previous studies commonly provided evidence for the presence of intact endocardium, myocardium and epicardium.[1,2] We recommend that fiber alignment and diameter should be included in the characterization of biological heart scaffolds as these could serve as valuable tools for evaluating structural preservation of decellularized heart. The bioartificial scaffold formed here can be functionalized with patient’s own material, and utilized in regenerative engineering.

ACKNOWLEDGEMENTS: No funding was received for this study.

Biodegradable microparticles with hierarchical topographical features influence VEGF secretion from mesenchymal stromal cells

C. Simitzi1 R. Day1

INTRODUCTION: Mesenchymal Stromal Cells (MSCs) are becoming increasingly important as therapeutic products due to the broad spectrum of trophic and immunomodulatory factors they secrete. The MSC secretome plays a role in angiogenesis and revascularization, immune modulation and tissue repair; however, there is a lack of methods suitable for controlling this effect. Evidence exists to show cell substrates with different topographical features can influence MSC behaviour. Therefore, manipulating the cell substrate could provide improved methods for controlling the secretome for new therapies; however, there is currently a lack of cell substrates suitable for implantation.

METHODS: The effect of implantable substrates consisting of highly porous biodegradable microparticles with hierarchical topographical features was investigated on MSC behaviour and secretome. Poly(DL-lactide-co-glycolide) microparticles were fabricated via the thermally-induced phase separation technique (TIPS). Three different polymer compositions of lactide/glycolide were studied. Microparticles were characterized in terms of surface topography and porosity. Human adipose-derived MSCs (ADMSCs) were incubated on the surface of the microparticles and cultured for 11 days in xeno-free medium. Cell growth on the microparticles was evaluated at six different time-points and compared with cells cultured on tissue culture plastic. The angiogenic activity of the ADMSC secretome was evaluated by ELISA and in vitro angiogenesis assays.

RESULTS & DISCUSSION: ADMSCs adhered and proliferated on all types of the microparticles. Vascular endothelial growth factor (VEGF) secretion was increased from cells cultured on the microparticles compared with cells cultured on tissue culture plastic. MSCs cultured on the microparticles remained viable after 12 days, were capable of migrating from the microparticles, and retained their lineage plasticity.

CONCLUSIONS: Our results show that attaching MSCs to biodegradable TIPS microparticles can influence the secretion of pro-angiogenic growth factors. This finding may provide a new method for re-vascularisation of tissue for regenerative medicine.

INTRODUCTION: Peripheral nerve injury (PNI) is a cause of medical consultation in more than 1 million patients worldwide, of which around 40% cases occur in Europe [1]. Graphene oxide (GO)-filled silk composite fibres hold great potential in tissue engineering due to their unique physicochemical and mechanical properties [2]. Herein, we assess the influence of GO incorporation within silk fibers as scaffolds for nerve tissue engineering.

METHODS: Regenerated silk fibroin (SF) in formic acid (FA) or hexafluoro-2-propanol (HFIP) at 10% w/v was electrospun into fibers with incorporation of GO at increasing concentrations (1%, 5% and 10% w/w GO/SF). Fibres were characterized by using field emission scanning electron microscopy (FESEM), Fourier-transform infrared (FTIR) and Raman spectroscopy. Antioxidant activity was assessed with a 2,2-diphenyl-1-picryl-hydrazyl (DPPH) assay. NG108-15 neuroblastoma/glioma hybrid cells (5,000 cells/cm²) at passage number P20 – P24 were seeded onto laminin-coated fibre scaffolds. Protein adsorption, metabolic activity, cell proliferation and viability were quantified; immunofluorescence of neuronal cell markers was investigated via confocal microscopy.

RESULTS & DISCUSSION: It is possible to control the silk fibre diameter by using FA (150 nm dia.) or HFIP (1.2 μm dia.) as solvent. Mean fibre diameter decreased (p< 0.01) with GO incorporation in FA fibres, with a flake lateral width distribution of around 170 nm. Fibre morphology was smooth and consistent for SF/HFIP with GO incorporation compared to SF/FA fibres. The overall chemical structure of silk remained unchanged as determined by FTIR, and Raman spectroscopy confirmed the presence of GO. Protein adsorption increased (p<0.01) with incorporation of GO in the fibres, as did the antioxidant properties of the scaffolds as a function of incubation time. In vitro analysis showed that the presence of GO enhanced the overall biological response of the scaffolds compared to SF alone (p<0.01), but this trend was non-significant for the highest GO inclusion investigated here.

CONCLUSIONS: These data illustrate the beneficial effects of incorporating GO in silk-based scaffolds for neuronal-like cell culture for cell growth and neurite extension. Further work is ongoing to develop conductive scaffolds that can enhance electrical signal propagation.

INTRODUCTION: A major limitation for the development of 3D engineered tissues is the absence of viable and perfusable vasculature [1-3]. As a precursor to vascularized adipose tissue, cylindrical channels were formed in a cast gelatin methacrylate (GelMA) construct by printings sacrificial networks of Pluronic F127. Human umbilical vein endothelial cells (HUVECs) were seeded and cultured within the 3D printed channels, while Adipose derived stem cells (ADSCs) were cultured in the GelMa prior to casting the 3D printed channels.

METHODS: GelMa was synthesized using the one pot synthesis method [2]. The hydrogel was characterized by NMR, surface tension, contact angle and DMA. Pluronic filaments were printed onto glass slides using a robotic printer I&J 7300-LF (Fishnar, UK). HUVECs (PromoCell, UK) were cultured on GelMa substrate, whilst ADSCs (ThermoFisher) were embedded within the GelMa. Live/Dead and Alamar Blue assays were used to assess the cells’ viability and proliferation respectively. Phalloidin staining was used to assess actin cytoskeleton organization.

RESULTS & DISCUSSION: Once methacrylation has occurred NMR peaks are seen at 6ppm and 2ppm corresponding to lysine and methacrylated grafts of hydroxyl groups. Viability assays confirmed that HUVECs and ADSCs were viable after 48 hours. Alamar Blue data indicated an increase in cell metabolism over a 7-day period. Phalloidin staining demonstrated good organization of the actin cytoskeleton of HUVECs on GelMa. Data on HUVECs injected within the printed 2D networks and 3D culture of ADSCs within the GelMa matrix will also be presented.

DISCUSSION & CONCLUSIONS: Collectively, our data illustrate that HUVECs could potentially grow and fully line the printed networks.

ACKNOWLEDGEMENTS: CC and FZ were supported by studentships from EPSRC and CSC.

INTRODUCTION: Over the last years, microvesicles and exosomes have become increasingly interesting and revealed a high potential to augment treatments for several clinical conditions. The bottleneck for pre-clinical and clinical testing remains the reliable production of exosomes with consistent quality and isolation under GMP conditions. Existing processes such as ultracentrifugation (UC), gradient centrifugation, etc are unreliable regarding purity and limited to small supernatant volumes (<200ml), and further-more difficult to transfer into GMP conditions. The aim of our study was to design a process and evaluation system for optimized production of exosomes using a scalable wave bioreactor system and tangential flow filtration (TFF), that can be transferred into a GMP environment.

METHODS: Mesenchymal stem cells (source: menstrual fluid) were cultivated on BioNocII carriers in a 10-liter wave bioreactor system (both cGMP-ready) and evaluated for survival / proliferation. Exosomes were harvested using particle-free culture medium for 3 days. Supernatants were transferred into the TFF system or UC respectively. Exosome yield and composition were assessed using Nanoparticle Tracking Analysis (NTA; NanoSight), Western Blot and ELISA. Functional testing included cellular uptake, immuno-suppression and angiogenesis migration assays.

RESULTS & DISCUSSION: MSCs cultivated on BioNoc II carriers secreted a higher amount of exosomes than 2D culture. Supernatants processed with TFF displayed a 1.5x higher particle yield as well as 7.3-9x higher exosome yield (UC:15%, TFF:90% purity). Cargo analysis revealed a higher amount of regeneration-associated proteins (FGF, HGF) in TFF exosomes. In all functional assays, TFF exosomes demonstrated a significantly higher potency (e.g. 2x higher autocrine uptake, 2.5x higher suppression of T-lymphocyte proliferation)

CONCLUSIONS: One of the prerequisites for translation of exosomes into the clinics is their efficient isolation without loss of activity, reflecting the characteristics of their cell of origin. Exosomes isolated with TFF displayed a higher activity in all functional assays, additionally to being present in higher quantity and purity. Given the decreased uptake, we speculate that high forces applied on exosomes during UC damage the integrity of the vesicle, leading to altered cellular uptake and possibly changes in their in vivo homing. Concluding, 3D culture and TFF display a scalable option for exosome production with increased biological activity, suitable for clinical application.

INTRODUCTION: The mechanical mismatch between stiff state of the art neuroprosthetic devices and soft neural tissue can lead to rejection or loss of function of the implants in chronic applications. To achieve seamless brain-machine interfaces novel tissue like conducting materials are needed.

METHODS: Here we report a multi-network hydrogel combining a non-covalent network consisting of the nanoclay Laponite with a covalent polyacrylamide network. To make the hydrogel scaffold electronically conductive poly(ethylene-3,4-diethoxy thiophene) (PEDOT) is polymerized around the polymer struts using an interfacial polymerization method. Therefore the gels are first soaked in 0.4 M ammonium persulfate in 1 M hydrochloric acid. In a second step the gels were incubated in a 0.4 M EDOT solution to polymerize PEDOT at the gel - EDOT interphase. An artificial extracellular matrix consisting of a starPEG (polyethylene glycol) layer containing a bone sialoprotein peptide sequence and the polysaccharide dextran sulfate is covalently bound to the hydrogel surface to enable cell adhesion.

RESULTS & DISCUSSION: The obtained multi-network hydrogel is combining electrical conductivity of 12 S/m, stretchability of 800% and tissue-like elastic modulus of 15 kPa. Laponite dramatically increases the conductivity of in-scaffold polymerized PEDOT in the absence of other dopants, while preserving excellent stretchability. Laponite further enables the immobilization of bioactive molecules. The artificial extracellular matrix coating allows for the adhesion, proliferation and neuronal differentiation of human induced pluripotent stem cells on the surface of the conductive hydrogels. Untreated gels on the other hand are cell repelling.

CONCLUSIONS: Due to its compatibility with simple extrusion printing and the afore mentioned mechanical, electrical and biological properties, our material promises to enable tissue-mimetic neuro-stimulating electrodes.
Automated 3D cell culture platform for investigating chemoresistance and efficacy of antibody-based therapeutics
A. Kletzmayr¹, F. Clement-Frey¹, D. Eberli², C.A. Millan¹,²
Presenting Author: Dr. Christopher Millan, christopher.millan@usz.ch

INTRODUCTION: Utilizing chemically modified chitosan and alginate, we developed a 3D culture platform for modeling acquired chemoresistance in ovarian, breast, lung, and prostate cancer cells. Cell seeding, media change, drug dosing, and endpoint assay were all performed on a commercially popular automated liquid handling robot suitable for large-scale screening.

METHODS: SKOV-3, A2780, SK-BR3, A549, and LNCaP cells were cultured in RPMI media supplemented with 10% FBS and 1% Pen/Strep. Cells were seeded in engineered microtissues (EMTs) as described elsewhere¹ with slight modifications. A Tecan Freedom EVO 100 was used to pipette 20ul oxidized alginate (oxAlg) per well of a U-bottom 96 well plate. Cells were resuspended in N-succinyl chitosan (sChi) at 106 cells/ml, and 5ul were pipetted into each well containing oxAlg followed by 30-minute incubation at room temperature to allow for crosslinking. Cells were then treated with a range of concentration of doxorubicin or paclitaxel for 72h. CellTiter Glo 3D was then used to determine viability following manufacturer’s protocol. Cells cultured in 3D were compared to standard 2D cultures via Western blot, proteomics (LC-MS/MS), and immunostaining.

RESULTS & DISCUSSION: Strikingly, after just 4 days in culture more than 10% of proteins identified by LC-MS/MS exhibited significantly altered expression in 3D including chemoresistance-associated proteins involved in stress response (e.g. mitochondrial dysfunction), metabolism (e.g. fatty acid beta oxidation and oxidative phosphorylation), and protein biosynthesis. Chemoresistance was confirmed by comparing their response to treatment with Taxol, a routinely employed first-line small molecule drug. Resistance indices (calculated by dividing IC50 values of cells cultured in 3D by those in 2D) ranged from ±10 in ovarian cancer cells to over 5,000 for breast cancer cells. In stark contrast, antibodies developed against targets known to be overexpressed in several cancer lines were shown to be more effective in suspending growth of cancer cells in the 3D model. In situ immunostaining confirmed antibody-target binding in 3D and increased expression of targets, including HER2 and Integrin α5β1 by cells cultured in 3D compared to 2D.

CONCLUSIONS: We present a highly scalable approach for culture of cancer cells in a chemically defined hydrogel that confers advanced stage phenotypes to encapsulated cells.

INTRODUCTION: Many tissues, such as bone, tendon and cartilage, possess an inhomogeneous structure due, in part, to biochemical gradients present during development. It is important to recapture these gradients in order to engineer tissues with native structure and function. To this end, we have developed different platforms that utilize fundamental physical forces to rapidly produce smooth biochemical gradients across different biomaterial systems.

METHODS: Bone morphogenetic protein 2 (BMP-2) gradients were presented across hydrogels laden with human mesenchymal stem cells (hMSCs). This was achieved using several configurations, including the use of magnetic fields to attract glycosylated superparamagnetic iron oxide nanoparticles sequestered with BMP-2. The gradient constructs were engineered for 28 d in osteochondral differentiation medium and characterized using immunohistochemistry, histology, and gene expression analysis.

RESULTS & DISCUSSION: We were able to generate a wide range of gradients across various hydrogel systems. Using hydrogels with BMP-2 gradients and hMSCs we were able to engineer robust osteochondral tissue constructs of cartilage tissue bearing a distinct mineralized cap. The tissue construct exhibited distinct cell types (chondrocyte and osteoblast), protein expression (distribution of collagen type II and osteopontin) and tissue mineralization (presence of HAP/β-TCP mineral). Interestingly, we observed the formation of a sharp mineral transition from a smooth BMP-2 gradient, an emergent property that mimics the formation of a tidemark at the native osteochondral interface.

CONCLUSIONS: Our approaches to engineer osteochondral tissue offer great versatility and could be readily tailored to other systems, offering new opportunities in interfacial tissue engineering.

Presenting Author: Claire Dooley, c.dooley9@nuigalway.ie
¹Regenerative Medicine Institute (REMEDi), National University of Ireland Galway (NUI Galway), Galway, Ireland

INTRODUCTION: Osteoarthritis (OA) is the most common degenerative diseases of the joint. Several factors contribute to the disease and it is a major cause of pain and discomfort in the elderly population [1]. Currently the only treatment strategies available are symptomatic and the mechanisms of the progression of the disease are still poorly understood. There is a need to identify early markers of the disease and potential therapeutic targets. CRISPR/Cas9 technology is a useful molecular tool to investigate these targets. DNA methylation screening identified Interleukin 16 (IL-16) as a hypomethylated marker in MSC chondrogenesis with high levels of the protein detectable at early and late stages of the disease. The aim of this study is to elucidate the role of IL-16 in OA progression.

METHODS: Bone marrow derived mesenchymal stem cells (MSCs), ethically obtained from donors, were differentiated in chondrogenic medium for 14 days. Changes in chondrogenic and hypertrophic markers were investigated by qPCR and immunofluorescence (IFC). A CRISPR/Cas9 system was designed to target domains of interest in IL-16 and the effects of its knock out were investigated in the MSC chondrogenic model.

RESULTS & DISCUSSION: qPCR and western blotting showed that it was the neuronal isoform (nIL-16) of this protein that was significantly upregulated in late stage OA patient samples. Preliminary IFC performed identified co-localization of nIL-16 with the calcium ion channel Transient Receptor Potential cation ion-channel sub-Family-V-member-4 (TRPV4) in the pericellular matrix of human OA chondrocytes (Figure 1). A CRISPR/ Cas9 strategy was designed to investigate whether nIL-16 and TRPV4 work together in a pathway contributing to chondrocyte hypertrophy and calcification that is seen in late OA. Guide RNAs (gRNAs) were designed to target the nIL-16 PDZ binding domains [2].

DISCUSSION & CONCLUSION: Data suggests IL-16 plays a role in OA progression. CRISPR is a useful tool to determine what it’s role potentially is.

INTRODUCTION: Bacterial invasion or dental trauma may cause irreversible pulpitis and necrosis of the dental pulp. Currently, the treatment of these pathologies is the cleaning, shaping and filling of the root canal system by a biomaterial. Recently, regenerative endodontics appeared, proposing new possibilities to restore a functional pulp tissue by tissue engineering and particularly cell homing. Cell-homing approach is based on the recruitment of resident stem cells by growth factors, which induce cell migration into a custom-made scaffold. Here, we study the influence of matrix stiffness in dental pulp stem cells (DPSCs) survival, proliferation and migration to define the best mechanical properties of a scaffold for dental pulp regeneration.

METHODS: The behavior of DPSCs was assayed on 1.5 kPa, 15 kPa, 28 kPa and MPa polydimethylsiloxane (PDMS) substrates coated with laminin. Cell migration was studied by time lapse sequences during 24h on a Nikon Ti-E microscope equipped with a 10x objective.

RESULTS & DISCUSSION: Immunofluorescence analysis revealed that extracted cells were positive for CD105, CD90 and CD73, which confirmed that they were mesenchymal stem cells. Soft substrates supported DPSCs viability, proliferation and formation of focal adhesion. Furthermore, the Yes-associated proteins (YAP) were predominantly localized within the nucleus. Interestingly, progressive softening PDMS substrates increased DPSCs migration. Myosin II and Arp 2/3 inhibitions didn’t prevent DPSCs migration but caused important change in the focal adhesion of these cells. Importantly, on 1.5 kPa PDMS substrates, in the presence of blebbistatin (Myosin II inhibitor) YAP was predominantly localized in the cytoplasm.

CONCLUSIONS: Studying the influence of matrix stiffness on DPSC behaviors is an important step to create more suitable scaffolds for pulp regeneration through cell homing. Here, we show that soft substrate might be suitable for cell homing as it doesn’t cause increased cell apoptosis and allows normal cell proliferation. The increased cell migration speed on 1.5kPa PDMS substrate make this stiffness particularly appropriate for pulp regeneration.

Liquefied capsules as 3D co-culture static and dynamic systems for bone regeneration
C.R. Correia1, S. Nadine, João F. Mano1

1CICECO – Aveiro Institute of Materials, Department of Chemistry, University of Aveiro, Aveiro, Portugal

INTRODUCTION: We developed a 3D liquified bioencapsulation system composed by the co-encapsulation of cells with surface-modified microparticles [1-3]. Here, we propose such capsules as an indirect triple co-culture system or as co-culture system for dynamic 3D culture.

METHODS: Alginate hydrogels were produced by electrospraying. Hydrogels encapsulating MC3T3-E1 or human adipose-derived stem cells (ASCs) and osteoblasts (hOBs) were coated with poly(L-lysine), alginate, and chitosan through layer-by-layer (LbL) assembly (n=12layers). The last layer was functionalized with alginate-RGD to promote HUVECs/fibroblast adhesion. Osteogenesis was evaluated up to 21 days. The angiogenic potential of capsules was evaluated by a chick chorioallantoic membrane (CAM) assay after 13 of inoculation. The dynamic system was performed using a rotary cell culture system.

CONCLUSIONS: A bone-like tissue was developed in vitro within the core of 3D liquefied bioencapsulation systems. Additionally, capsules allowed the adhesion of an external co-culture of HUVECs and fibroblasts, thus acting also as a cellular supportive on the outside. This may represent a great advantage for a proper tissue integration after in vivo implantation. As demonstrated by the CAM assay, capsules were able to recruit new vessels at a similar level compared to the positive control. Moreover, capsules cultured in a 3D dynamic culture system demonstrated that osteogenesis was enhanced compared to static cultures, and remarkably occurred in basal medium, thus in the absence of osteogenic differentiation supplements.

Figure 1: (left) Triple co-culture of MC3T3-E1 encapsulated within liquefied and multilayered capsules, and human fibroblasts and HUVECs on the outside environment adhered to the membrane.
Figure 2: (middle) Optical microscopy of CAMs with (A) capsules or (B) with basic fibroblast growth factor-2 (control+). (C) New vessels recruitment quantification. Control- stands for CAM with α-MEM/1% penicillin/streptavidin. Scale bars are 50 µm (**p<0.01).

INTRODUCTION: Are biomaterials and growth factors alone sufficient for the treatment of non-healing long bone defects? The question can be answered with yes, while the safety for the patients is not guaranteed. Current approaches, such as surface absorption and encapsulation are based on the incorporation into the scaffold of the osteogenic growth factor bone morphogenetic protein 2 (BMP2). However, these methods require high doses of protein that are associated to several severe side effects. In order to overcome these problems we aim to immobilize a newly produced BMP2 variant in a site directed manner. The new BMP2 variant harbors a non-natural amino acid in each chain of the mature polypeptide allowing a site-specific coupling by “click chemistry”. With this method lower doses of the covalently coupled protein would be required to induce bone formation and thus eliminating the adverse events for patients.

METHODS: The BMP2 variant (BMP2 Azide) was expressed in E.coli and analyzed in terms of purity and biological activity in vitro. Using copper-free click chemistry reaction the protein was coupled to collagen microspheres. The efficiency of the coupling reaction was validated with different analytical methods. Finally, BMP2-functionalized microspheres were tested in vivo in a subcutaneous rat model. Bone volume and density were evaluated by micro-computed tomography (µCT) during the animal experiment. Newly formed bone was histologically analyzed.

RESULTS & DISCUSSION: BMP2 Azide showed the same bioactivity as the wild type BMP2 (BMP2 WT) and maintained its bioactivity also after the coupling reaction to microspheres. Moreover, the BMP2-functionalized microspheres induced ectopic bone formation in vivo. Histological examination of the formed ossicles revealed clear morphological differences between covalently coupled BMP2 Azide and adsorbed BMP2 WT used as control. The diffusion mechanism of BMP2 WT towards the subcutaneous environment induced a shell like structure, while the non-released BMP2 Azide induced a more uniform bone formation.

CONCLUSIONS: The covalently coupled BMP2 approach defines a new strategy to improve safety by avoiding severe side effects. This interesting method could result in the replacement of the currently used clinical devices.

INTRODUCTION: Intravital microscopy techniques are currently performed using highly invasive window chambers [1]. Moreover, there exist no device providing a specific tracking geometry to reposition the field of view of the microscope for repeated analyses. We developed a miniaturized imaging window, the Microatlas, which can be implanted subcutaneously and allows repeated observation in vivo of foreign body reactions, for example to the implantation of a biomaterial. The device hosts a miniaturized scaffold able to guide cell migration. By applying two-photon fluorescence microscopy to the Microatlas, once implanted in vivo and repopulated by cells and blood vessels, it is possible to observe and quantify reactions in the same animal and tissue district, at different time points. Here, we grafted the Microatlas in living chicken embryos to conduct in vivo validation assays.

METHODS: The Microatlas scaffolds were fabricated by two-photon laser polymerization on circular glass coverslips (Ø:5-12 mm), with a biocompatible photoresist, SZ2080 [2]. The Microatlas is composed by several micro grids (500x500x100 μm³). Reference structures were integrated in the grid to allow the microscope field-of-view repositioning at different time-points. The chicken embryo ex ovo culture was defined and optimized. Optimal implantation time points were selected. CD31 antibody staining was employed as a marker of inflammatory and endothelial reactions and DRAQ®TM was employed as a nuclei marker. Then, the device was implanted, and it was inspected by two-photon fluorescence and confocal microscopy.

RESULTS & DISCUSSION: Confocal inspections at Microatlas implantation sites highlighted the propensity of the recipient tissue to grow inside the micro grids. Two-photon fluorescence acquisitions of label-free specimens showed the presence of a layer of collagen type I, placed mainly around or nearby the implanted Microatlas. Confocal microscope images of immunofluorescence assays revealed a strong presence of CD31 signal as a higher presence of inflammation-related cells inside the Microatlas, compared to control (i.e. glass coverslip) samples. Confocal microscope images allowed cell quantification inside the Microatlas, providing a cell density estimation.

CONCLUSIONS: The Microatlas induced a quantifiable localized reaction inside its microscaffolds, both in terms of cell repopulation, immune response and collagen generation: all signs of a probable foreign body reaction. Thus, our device can be used as a powerful imaging window for intravital fluorescence microscopy.

INTRODUCTION: Cartilage-mimicking collagen hyaluronate scaffolds have demonstrated significant regenerative capacity in directing de novo chondrogenesis preclinically1 and clinically1. However, the ability of these materials in supporting long term cartilage regeneration still needs to be assessed and represents an area of significant scientific interest. Therefore, the aim of this study was to investigate the incorporation of collagen type II (a potential chondro-inductive component2), within collagen hyaluronate scaffolds to assess its role in modulating stable cartilage regeneration.

METHODS: A series of porous collagen (0.5% w/v) hyaluronate (0.05% w/v) scaffolds were manufactured with different ratios of collagen type I:type II (1:1; 1:3; 1:5) by using a freeze-drying technique as previously described3. Scaffolds were subsequently cultured with $5 \times 10^5$ rat-mesenchymal stem cells (MSCs) in vitro under chondrogenic conditions for 28 days. Then, they were analysed histologically, by means of sulphated GAG and DNA quantification and by performing a uniaxial compression test (Zwick Z005, GmbH, Germany).

RESULTS & DISCUSSION: The incorporation of collagen type II in the ratio 1:1 to collagen hyaluronate scaffolds significantly improved (p < 0.001) both cell viability and cartilage matrix production without altering the overall mechanical properties. These scaffolds incorporating collagen type II resulted in 4-fold higher level of DNA and 3-fold of sulphated GAG. Furthermore, histology revealed a more homogenous cell infiltration and sulphated GAG distribution inside the matrix.

CONCLUSIONS: The addition of collagen type II to collagen hyaluronate scaffolds demonstrated an added chondrogenic benefit, suggesting them as potential cartilage-mimicking scaffolds capable of generating more stable cartilage. This simple, off the shelf approach could offer the possibility of long term stable cartilage tissue repair for localised cartilage lesions of the knee.

INTRODUCTION: Low back pain, caused by intervertebral disc (IVD) degeneration, represents a global disability [1]. Current treatments are highly invasive and inefficient in the long-term, therefore minimally-invasive therapies are emerging. Self-assembling peptide hydrogels (SAPHs) represent potential candidates as injectable cell carriers, due to their tissue biomimicry that supports cell viability and differentiation [2]. Moreover, the advent of graphene has made graphene-containing materials appealing to direct cell fate [3]. Here, we incorporated graphene oxide (GO) within a SAPH to develop novel peptide-GO hydrogels as potential scaffolds for degenerate IVDs.

METHODS: Peptide-GO hydrogels were prepared by incorporating 0.5 mg/ml of GO (mean size <5µm) within 10, 15 and 20 mg/ml of FEFKFEFK (F8) peptide hydrogels. Hydrogel structure at micro and nanoscale was assessed via FTIR, AFM and TEM. Mechanical properties and gel injectability were studied via oscillatory rheometry. Bovine nucleus pulposus cells (BNPCs) were encapsulated in peptide/GO and cultured in 3D for 7 days, while alamarBlue® and LIVE/DEAD assays were used to measure metabolic activity, cell morphology and viability at 1, 4 and 7 days after encapsulation.

RESULTS & DISCUSSION: GO was successfully incorporated in F8 hydrogels, showing different levels of interactions with the peptide network. The presence of GO enhanced the mechanical properties of native peptide hydrogels, achieving storage moduli (~12.8 kPa) comparable with the human nucleus pulposus tissue (~10 kPa). Peptide-GO hydrogels showed excellent biocompatibility, preserving cell morphology, high viability and metabolic activity over time. Moreover, nanocomposites showed clear ease of injectability, making them suitable for minimally-invasive applications.

CONCLUSIONS: Collectively, these data showed that GO can be incorporated within SAPHs to create potential mechanically-reinforced scaffolds for novel IVD tissue engineering approaches.

INTRODUCTION: Due to their unique properties, composites materials for Bone Tissue Engineering based on the combination of a biocompatible, biodegradable and highly porous polymer reinforced by various filling substances gained increasing interest [1]. The aim of our study was to develop a hybrid material bonding an elastomeric matrix to bioceramic particles while serving as a matrix for bone regeneration.

METHODS: PolyHIPE technique had been used to synthetize the composites based on ref [2]. Mechanical behaviour, morphological, chemical and elemental analyses were determined by several techniques such as SEM, EDX, compression test, volumetric absorption, colorimetric assay and infrared spectroscopy. Density measurements were carried out by pycnometry. In vitro assays were conducted in order to determine cells viability and migration within the scaffolds up to 30 days while in vivo tests were performed on segmental-like defect on rats models.

RESULTS & DISCUSSION: SEM, morphological analyses and volumetric absorption revealed the interconnected porosity of composites scaffolds. Infrared spectroscopy and elemental analysis revealed the presence of PO43- groups, phosphorus and calcium. Alizarin Red staining showed the homogeneous distribution of the bioceramic particles within the elastomeric matrix. Density measurements allowed to determine the amount of filling particles. Compression test revealed the elastomeric behaviour of the composites. In vitro test demonstrated that cells were able to migrate, proliferate, differentiate into the whole volume of the composite. During in vivo assays, neither complication, nor sign of inflammatory response or scaffold rejection was noticed. A bone repair was observed.

CONCLUSIONS: The collected data showed the reinforcing-effect of bioceramic granules while maintaining the elastomeric properties. In vitro tests revealed the osteoconductive properties of biocomposites. In vivo assays confirmed the biocompatibility, osteoinductive properties and bone regeneration potential of the hybrid materials. Degradation studies and bioactivity analyses through the evaluation of apatite formation in simulated body fluids are currently investigated.

Optimal loading regime to promote cartilage and bone development in vitro
C. Parisi¹, N.C. Nowlan¹
Presenting Author: Cristian Parisi, c.parisi@imperial.ac.uk
¹Department of Bioengineering, Imperial College London, London, UK

INTRODUCTION: Mechanical stimulation is essential for normal cartilage and bone prenatal development [1,2]. A better understanding of what mechanical stimulation is optimal for skeletal development would provide valuable insights for recapitulation of these processes for tissue engineering of replacement cartilage and bone [3]. The aim of this study is to determine the optimal regime of mechanical stimulation (frequency and duration) for cartilage and bone development, using embryonic chick limb explants in an in vitro mechanostimulation bioreactor system [2].

METHODS: Embryonic chick hindlimb explants were cultured in vitro on polyurethane foam supports in a mechanostimulation bioreactor (Ebers TC3) for six days. A flexion regime (14±4°) induced by a 3-mm uniaxial compressive deformation was applied to all explants for two hours [2], one (1TD), two (2TD) or three times per day (3TD), in a sinusoidal waveform at frequencies of 0.33Hz (low frequency, n=6) and 0.67Hz (high frequency, n=6). Static cultures were performed as controls (n=12). Cultured explants, stained for cartilage and mineralised tissue using Alcian Blue and Alizarin Red, were scanned in 3D using optical projection tomography and assessed for 3D joint shape and extent of diaphyseal mineralisation. One-Way ANOVA and Tukey’s post-hoc test were performed to verify if significant differences existed between groups (p<0.05).

RESULTS & DISCUSSION: Higher frequency and longer duration of loading increased both mineralization and cartilage growth. Frequency effects were dominant, with most of the significant differences being between the high and low frequency groups. However, there were consistent trends due to increased duration of loading for both bone and cartilage development.

CONCLUSIONS: We found that a longer duration of loading at a higher frequency led to the most cartilage growth and mineralisation in the developing chick limb in vitro. The next steps for this work are to investigate the effects of this regime in cartilage and bone tissue engineering applications.

INTRODUCTION: The lack of neurotrophic factors (NTFs) following peripheral nerve injury leads to incomplete nerve regeneration and partial functional recovery. In this work, a new methodology developed by our group to produce silk fibroin conduits was used, allowing to incorporate and release bioactive Nerve Growth Factor (NGF) or Glial cell-derived neurotrophic factor (GDNF).

METHODS: Enzymatically-crosslinked silk fibroin (SF) conduits were produced by taking advantage of the tyrosine groups present in the structure of silk fibroin. In this system, hydrogen peroxide was used as the substrate and horseradish peroxidase as the enzyme. NTFs were incorporated in the silk fibroin conduits using two different methods: i) mixing the NTFs prior to silk crosslinking and ii) soaking the produced conduits in NTF solution. The release profiles were studied by means of performing ELISA. The bioactivity of the released NTFs was confirmed by in vitro assays, using neonatal rat pup dorsal root ganglion (DRGs) explants. The selected formulation was implanted in a 10 mm sciatic nerve defect in rats for 6 weeks and compared to autografts and plain SF conduits (5 rats per formulation).

RESULTS & DISCUSSION: The soaked formulations were found to release significant higher amounts of NTFs as compared to the crosslinked ones. Biological assays with DRGs allowed us to select soaked GDNF 4 µg/mL as the most promising formulation, with longer and denser axon sprouting. In the in vivo study, 80% of the animals transplanted with soaked GDNF 4 µg/mL responded positively to the nerve pinch test, as compared to 20% of animals receiving the plain SF conduit. The treatment with soaked GDNF 4 µg/mL significantly reduced muscle weight loss compared to the plain SF conduit. Furthermore, regeneration across the 10 mm nerve gap was detected in 100% of the autografts, 100% of the silk + GDNF and 80% in the SF conduits.

CONCLUSIONS: The previously described method for SF conduits production revealed to be very useful and versatile for NTFs incorporation. The incorporation was successful and preserved the bioactivity of the NTFs when released, as seen by the in vitro assays. Overall, the hypothesis that the addition of GDNF to the SF nerve conduit would yield positive results as compared to plain silk conduit was demonstrated and the nerve regeneration was found to be robust and comparable to autograft, when using the soaked GDNF at 4 µg/mL conduit.

INTRODUCTION: Bone regeneration in osteoporotic patients is one of the most challenging topics of tissue engineering [1]. In this work, we have designed different silicon-hydroxyapatite 3D scaffolds by means of controlling the crystalline degree of the bioceramics and associating it with VEGF, thus fostering bone regeneration in an osteoporotic environment.

METHODS: Macroporous scaffolds were prepared by robocasting from SiHA as precipitated powders. After printing, the specimens were treated at 700°C and 1150°C to obtain nanocrystalline (NanoSiHA) and highly crystalline (SiHA) scaffolds, respectively. VEGF was immobilized on their surface. Mature endothelial EC2 and pre-osteoblastic MC3T3-E1 cells were cultured on the scaffolds and proliferation and differentiation were determined. Six months before the implantation, six 4-year-old female Merino sheep underwent a laparoscopic bilateral ovariectomy, a low-calcium diet (0.5%) and corticosteroids administration to reproduce similar conditions as osteoporosis in humans [2]. The scaffolds were implanted in cylindrical defects (10x13mm), created in the proximal tibia epiphysis. After 12 weeks, sheep were sacrificed, and the bone segments were histologically analyzed.

RESULTS & DISCUSSION: In vitro studies evidenced that endothelial EC2 cell proliferation was fostered in those scaffolds with immobilized VEGF, whereas proliferation and differentiation of pre-osteoblastic MC3T3-E1 cells were significantly enhanced in SiHA scaffolds. The in vivo study evidenced that highly crystalline SiHA associated to VEGF promoted significantly higher bone ingrowth (with 20 ± 6 % of the scaffolds volume colonized by new bone), thicker trabeculae (0.16 ± 0.04 mm), higher presence of osteoblasts and enhanced blood vessel formation. On the contrary, NanoSiHA with and without VEGF promoted a slightly higher inflammatory response and a significantly higher presence of osteoclasts.

CONCLUSIONS: Scaffolds made of bioceramics with highly crystalline microstructures facilitate adhesion and proliferation of osteoblasts, whereas the presence of VEGF promotes angiogenesis. The combination of both factors stimulates bone regeneration even in osteoporotic environments.

**INTRODUCTION:** Next generation magnetic bioprinting (NextGMB) is a promising strategy for creating geometrically complex human tissues grown in the lab. The combination of drop-on-demand bioprinting with a magnetic field enables the fabrication of native-like, functional tissues with controlled biochemical and mechanical signals and multiscale architecture.

**METHODS:** Magnetic 0.5 % agarose – 0.2 % collagen bioinks were loaded with 10 v/v % streptavidin-coated iron nanoparticles and added to the bioprinter head. A custom-designed 3D-bioprinter was mounted with a micro-valve for drop-on-demand bioprinting. Collagen fiber alignment was triggered in magnetic bioinks during the bioprinting process in the presence of a 2 mT magnetic field that forced iron nanoparticles to travel through the constructs. Human primary chondrocytes were isolated using standardized protocols and loaded in the magnetic bioink. Multi-layer constructs were fabricated with a gradient architecture like a native tissue. The constructs were incubated statically and dynamically for 21 days. Collagen fiber alignment was visualized by the non-linear optical effect of second harmonic generation (SHG) using a two-photon microscope at 840 nm excitation wavelength and scanning electron microscopy. Cell viability and distribution and ECM production were analyzed by histology, immunocytochemistry and qPCR.

**RESULTS & DISCUSSION:** Collagen fiber alignment in magnetic bioinks was confirmed after bioprinting exposed to a 2 mT magnetic field, contrarily to control samples that showed random fiber orientation. Fiber alignment additionally impacted the mechanical stiffness of the constructs, which was found significantly higher in bioprinted hydrogels with aligned collagen fibers compared to samples with random fibers. Histological evaluation showed homogeneously distributed cells in bioprinted constructs with aligned collagen fibers. Over 99 % of the cells were viable in the presence of the magnetic particles, indicating that these were non-cytotoxic. Interestingly, COL II expression was statistically higher in bioprinted bilayer constructs compared to single layer constructs with either random or aligned fibers, as shown by qPCR.

**CONCLUSIONS:** This study demonstrated that it is possible to align collagen fibers in magnetic bioinks in real-time whilst bioprinting. It was shown that unidirectional fiber alignment in bioprinted hydrogels can improve their mechanical stiffness. Bioprinted native-like 3D tissues showed increased remodeling properties when fabricated as multi-layered constructs compared to single layered samples. This study holds promise for the fabrication of native-like tissues with mimicking architectures and controlled mechanical signals.

**ACKNOWLEDGEMENTS:** This project was supported by a START Grant from the Medical Faculty, RWTH Aachen University Hospital and by the Core Facility “Two-Photon Imaging”, a core Facility of the Interdisciplinary Center for Clinical Research (IZKF) Aachen within the Faculty of Medicine at RWTH Aachen.
Blood flow and O₂-transport assessment in biohybrid oxygenators

D. Dipresa¹, M. Pflaum¹, A. Haverich¹,², S. Korossis¹,²,³

Presenting Author: Daniele Dipresa, dipresa.daniele@mh-hannover.de

¹Lower Saxony Centre for Biomedical Engineering Implant Research and Development, Hannover Medical School, Hannover, Germany ²Department of Cardiothoracic, Transplantation and Vascular Surgery, Hannover Medical School, Hannover, Germany ³Cardiopulmonary Regenerative Engineering (CARE) Group, Centre for Biological Engineering, Loughborough University, United Kingdom

INTRODUCTION: Extracorporeal hollow-fiber (HF) membrane oxygenators (ECMOs) are the main ones used clinically. Contact of the blood with the ECMO causes thrombus formation and short-term use (2-4 weeks). Endothelialization of the HF gas-exchange membranes is a solution to thrombogenicity. However, abnormal shear stresses and inhomogeneous blood flow in the ECMO can affect O₂-transport and physical environment and thus, the function and status of the seeded endothelial cells (ECs). The study developed computational fluid dynamics (CFD) models of the iLA® (Novalung) and a rodent HF oxygenator, to assess the effect of their haemo-dynamics and O₂-transport on seeded ECs.

METHODS: Coupled O₂-transport and blood-flow 3D CFD models were developed in Ansys Fluent to predict pO₂, O₂ saturation, blood velocity, and flow-induced shear stresses on the HF walls (and thus on seeded ECs). The heterogeneous models included the full HF architecture and blood regions. The HF wall thickness defined the first diffusion region, whilst the haemoglobin-bound-O₂ contribution was modelled using the effective diffusivity of O₂. The convection-diffusion equation was used to predict the pO₂ distribution and O₂ saturation in the interstitial and fiber regions. The blood was considered as a shear dependent fluid (non-Newtonian, Carreau model).

RESULTS & DISCUSSION: The simulation results suggested that the resistance to O₂ diffusion across the HF wall, void fraction and HF configuration and diameter played a significant role in the O₂ transport efficiency and the magnitude and distribution of the HF wall shear stress (WSS). WSS was between 0.3-2.5 Pa for clinically-relevant blood flow rates (Figure 1). Predicted regions of low blood velocity were associated with very low WSS (<0.1 Pa) and areas of recirculating flow. These regions would match regions with higher incidence of thrombus formation and clotting.

DISCUSSION & CONCLUSION: This study developed important CFD and O₂-transport models for assessing ECMO performance. The models predicted low WSS and recirculating flow regions, suggesting modifications in the design of these ECMOs in order to support effective endothelialization.

INTRODUCTION: There is a lot of controversy on how human mesenchymal stromal cells (hMSCs) are defined. This is mainly because hMSCs, when injected in vivo neither divide into new daughter cells and retain their stem cell potential, nor are they able to become quiescent. We hypothesized that cells need a more physiologically relevant micro-environment that allows them to maintain their phenotype. To do so, we tested a low RGD functionalized alginate hydrogel cell culture system, which mimics the bone marrow’s physical property, allowing hMSCs to remain quiescent and maintain their multipotency.

METHODS: hMSCs were in alginate (3D) or on TCPS (2D) and cultured with 10% FBS (Normal) or without (Starving). Cell cycle was analyzed by propidum iodide cell staining. Proliferation was assessed by EdU staining. Cell viability was assessed with live/dead assay with calcein/ethidium homo-dimer and metabolic activity was monitored with PrestoBlue assay. mRNA expressing was assessed by qPCR analysis and protein expression was analyzed by western blot.

RESULTS & DISCUSSION: hMSCs cultured in hydrogels survived while they lacked the ability to proliferate. When the encapsulated hMSCs were retrieved after 7 days, they retained their multipotency and could differentiation into the three classical linages. Moreover, the encapsulated hMSCs presented a significant upregulation of quiescent markers FOXO3, EZH1, and p27 when compared to 2D. These encapsulated hMSCs expressed nuclear envelope statin (NES), a novel quiescence marker, and their cell-cycle analysis showed a decrease in the S and G2 phase when compared to 2D hMSCs culture. Also, encapsulated hMSCs showed an upregulation of Retinoblastoma 1 (RB1) at the protein level. mTOR and mTOR are currently being investigated.

CONCLUSIONS: In conclusion, we demonstrate that low RGD functionalized alginate hydrogel maintained hMSCs phenotype. We think that in long-time in vitro culture, their multipotency and viability was not compromised due to the cells retaining their quiescent state. This state was further characterized by an upregulation of enzymes that enhance and promote RB1 activity which is a cell cycle regulator that blocks G1 to S transition.

INTRODUCTION: Current treatments options for articular cartilage repair such as microfracture remain sub-optimal. While microfracture (MFX) is a well-established and well-accepted treatment for chondral defects, the repair tissue generally consists of bio-mechanically inferior fibro-cartilage. The overall goal of this study was to develop and evaluate an articular cartilage (AC)-ECM derived scaffold as a single-stage, cell-free implant to enhance articular cartilage regeneration following microfracture. To this end, we sought to: (1) evaluate if AC-ECM is indeed more chondro-inductive compared to type I collagen scaffolds typically used in cartilage repair; (2) develop highly porous and elastic scaffolds from AC-ECM and assess their capacity to support chondrogenesis in vitro; and (3) test the hypothesis that such AC-ECM derived scaffolds can enhance cartilage regeneration following microfracture in a caprine model of chondral defect healing.

METHODS: Solubilized AC and ligament was lyophilized to form 3D porous scaffolds. The in vitro chondrogenic potential of the scaffolds was assessed by seeding the scaffolds with mesenchymal stromal cells (MSCs), while the immunogenicity was assessed by seeding with human macrophages. In the pre-clinical model, bi-lateral surgery was performed on all goats with intra-animal MFX only controls in all animals. 6mm diameter by 1mm deep chondral defects were created in the medial condyles. Tissue repair was evaluated at 6 months post-surgery.

RESULTS & DISCUSSION: Solubilized AC-ECM derived scaffolds were found to be highly porous and elastic, and in vitro supported superior chondrogenesis to scaffolds derived from ligament ECM. Furthermore, the AC-ECM scaffolds did not elicit a negative immune response when seeded with macrophages. An improved level of cartilage repair was observed in animals treated with the AC-ECM scaffolds in conjunction with MFX when compared to animals treated with MFX alone.

CONCLUSIONS: This study demonstrates that MFX can be positively augmented with the use of an AC-ECM derived scaffold. To further enhance the quality of AC repair, we are currently evaluating the combination of an AC-ECM scaffold, coupled with either transforming growth factor-β3, or rapidly isolated infrapatellar fat pad stromal cells, in a caprine cartilage defect model.

INTRODUCTION: Tumor progression follows a complex cascade of events, including changes in the morphodynamics of invading protrusions. Recent evidences have shown that tumor cells modulate protrusion type to optimize their invasion in 3D [1]. However, the role of protrusion fluctuations in this mechanism is unclear [2]. Herein, we analyze their role and define novel parameters (signature) of tumor invasiveness.

METHODS: Human A549 lung adenocarcinoma and MCF7 breast cancer cells (ATCC) were encapsulated for 3 days into a collagen I (Gibco) 3D matrix at low density (10^5 cells·ml^-1) to form μ-spheroids. For drug experiments, cells were incubated with 0.1, 1.0 and 10 μg·ml^-1 of doxorubicin (DOX; Sigma) and 1.0 μg·ml^-1 C3 Rho inhibitor (Cytoskeleton, Inc). Tumor protrusion fluctuations were monitored by time-lapse. Biophysical parameters: frequency of probing (νp) – # of protrusions that elongate and retract over time; stabilization lifetime (τs) – dwelling time of an extended tumor protrusion.

RESULTS & DISCUSSION: Protrusion fluctuations displayed a distinct morphodynamics, which depended on tumor metastatic capability. Non-metastatic A549 μ-spheroids showed a lower νp and larger τs compared to more-metastatic MCF7. The addition of DOX perturbed protrusion fluctuations, increasing (decreasing) νp (τs) in both cell types, resulting in an enhanced tumor invasiveness. Interestingly, we found a linear correlation between both parameters, which correlated with the invasive potential of cells. We also found that Rho inhibition modulated νp and τs, which abolished the invasive capacity of tumors. Next, we used a tumor-on-chip model integrating our μ-spheroids and endothelial cells to mimic the native scenario. The endothelial cells affected protrusion dynamics and orientation, suggesting a crosstalk between both cell types. Finally, all these observations were encoded into a phase diagram, which provided a novel landscape capable to ‘predict’ the invasiveness of tumors based on their fluctuations.

CONCLUSIONS: These data illustrate that protrusion fluctuations are key players in the physicochemical mechanism of tumor invasion, and are governed by νp and τs.

Biogenic metallic nanoparticles. A nanometric trojan horse approach

D.M. Cruz

Presenting Author: David Medina Cruz, medina.dav@husky.neu.edu

Chemical Engineering Department. Northeastern University, Boston, MA, 02115, USA

Antimicrobial resistance to antibiotics (AMR) and cancer and two of the main concerns that the healthcare system should face nowadays. Current drugs and antibiotic treatments are becoming ineffective or have plenty of drawbacks. Therefore, new alternatives are needed. Despite the increase in the use of nanostructures in the biomedical field, traditional synthesis of such materials is subjected to several disadvantages, such as the production of toxic-by-products and harsh conditions. Green nanotechnology is presented as a suitable answer, allowing the generation of nanostructures in a quick, cost-effective and environmentally-friendly approach. Pathogenic bacteria and human cells - both cancer and healthy ones - were used for the synthesis of metallic nanoparticles similarly. Bacteria and cells are cultured in the presence of metallic salts under standard conditions until the generation of nanoparticles, that is followed using microscopy and spectrophotometric techniques. After purification, nanoparticles are used as antimicrobial and anticancer agents using colony counting unit assays and MTS assays, respectively, as well as characterized. Pathogenic bacteria are used for the synthesis of bacteriogenic metallic selenium nanoparticles that were characterized in terms of size, morphology, and composition. These agents were employed as suitable agents with antimicrobial activity against the same bacteria that synthesized them, showing low cytotoxicity for human dermal fibroblasts (HDF) cells. The synthesis of metallic nanomaterials using cancer and healthy cells -HDF and HFOB- is reported. Pure metal nanoparticles –palladium or platinum- and bimetallic structures – such as gold-platinum- are readily synthesized using the cells, and after purification, they are used as anticancer agents. Microbiological agents are successfully used as a synthetic machine for the generation of metallic nanoparticles of different compositions with biomedical properties. Therefore, they are presented as a suitable approach for the synthesis of nanomaterials in a green fashion, overcoming the limitations of traditional nanotechnology.

INTRODUCTION: The wall shear stress (WSS) is the frictional force per unit area exerted at the interface of the flowing blood and the endothelium. WSS is a potent stimulus capable of evoking variable phenotypes in endothelial cells (EC)¹,². In adults, two pathways are alternatively involved in inducing EC quiescence conferring a protective effect on endothelium or EC activation and pro-inflammatory signalling inducing endothelium dysfunction and pro-inflammatory and pro-thrombotic effects. Physiological WSS patterns were decomposed correlating to imperative features such as TAWSS, peak WSS, temporal WSS gradient and OSI. The overarching aim is to systematically evaluate the features as mediators of venous EC activation and signalling.

METHODS: The study analyses the in vitro and ex-vivo WSS exposure using a Cone and Plate device with a custom designed ex-vivo perfusion system. In-vitro experiments: To decompose the driving factors correlated to WSS in-vivo, 10 idealised waveforms were created ranging for WSS peak magnitude of 0.5 to 2.5 Pa, t-WSSG from 2 to 20 Pa/s and from 0 to 0.5 of oscillatory shear index (OSI) value. Evaluation of differential protein and gene expression was completed using RT-PCR, Western Blot and Immunofluorescence staining. Preferential analysis was completed on NF-kB, PECAM-1, a-SMA and KLF-2 due to previously described relationship with vascular disease. Ex-vivo experiments: Using a custom designed perfusion system, idealised physiological waveforms were used to exposed surgically created bovine AVF tissue samples for up to 2 weeks to correlate the tissue response to hemodynamics presented in in-vitro model. H&E and immunofluorescent staining techniques were used to compare the tissue’s structural remodelling and differential protein response.

RESULTS & DISCUSSION: Our results indicate that WSS waveforms with a peak magnitude of 1.5 or 2.5 Pa can induce a protective phenotype in ECs in culture in terms of KLF-2, KLF-4, IL-8 and VCAM-1 expression. By presenting a reverse phase or decreasing TAWSS of the waveforms with a peak of 1.5 or 2.5 Pa, the flow-induced protective effect is maintained. A WSS peak of 1.5 Pa show to be sufficient to induce protective pathways. Pro-inflammatory gene expression showed no differences in the expression of two subunits of NFkB (NFkb-1, NFkB-3). Differential expression of protective and pro-inflammatory proteins colocalising with areas of disturbed hemodynamics in the ex-vivo model.

CONCLUSIONS: The effects of unsteady WSS profiles, atherogenic time-averaged WSS threshold should be reconsidered and reduced significantly, at least for venous EC. Similarly, preliminary results from ex-vivo tests suggest differential protein expression at the sites of disturbed WSS patterns within the tissue samples correlating with previous flow studies.

INTRODUCTION: Human mesenchymal stem cells (hMSC)-based therapies have shown some positive effects in regenerating injured myocardium. However, their therapeutic effect is limited by their engraftment capacity. Indeed, most of the MSCs die during the delivery and fail to adhere and therefore to survive once injected [1]. A method of fluorescent staining with silica nanoparticles (SiO₂NPs) was developed in order to track hMSCs in vivo. The uptake of SiO₂NPs was shown to be well-tolerated by hMSCs. It was shown that during in vitro static culture, SiO₂NP internalization increased the area and the maturation level of hMSC focal adhesion complexes, and enhanced the expression of Connexin-43 [2]. Based on these findings, we hypothesized that the internalization of SiO₂NPs could enhance MSC adhesion also in dynamic condition, resembling interstitial shear stresses physiologically present in the contractile myocardium [3].

METHODS: Human MSCs were isolated from three different bone marrow donors. hMSCs were incubated with 50 ug/ml SiO₂NPs overnight [2]. hMSCs without SiO₂NPs were used as control. Custom-made shear stress chambers were used to mimic the heart physiological shear stress of 0.43 dyne/cm². The adhesion capability of hMSCs (pre-loaded with Calcein) was evaluated first on a fibronectin-coated glass and later on a rat-origin cardiac cell monolayer (80% cardiomyocytes and 20% fibroblasts) following two hours. Connection between the hMSCs and the cardiac monolayer was evaluated by assessing the transfer of FITC-labeled Calcein.

RESULTS & DISCUSSION: On fibronectin substrates the adhesion area of SiO₂NP-hMSC focal adhesion complexes was higher than in control cells (5122 ±701 and 1469 ± 236 cm², respectively). The adhesion area on a cardiac layer was also superior in SiO₂NP-treated MSCs. Nanoparticle-treated MSCs were also characterized by the highest number of polarized adhesion focal complexes (between 7-13 compared to 3-6 in control MSCs). Moreover, SiO₂NP-MSCs were capable to transfer Calcein in to the highest number of cardiac cells (20%±10 vs 10% ±12).

CONCLUSIONS: SiO₂NP incorporation clearly increases the hMSC adhesion capacity, showing a high potential to improve MSC engraftment and their therapeutic effect in vivo upon cell injection.

A novel mechanism for the protection of embryonic stem cell derived tenocytes from inflammatory cytokine interleukin 1 beta

INTRODUCTION: Tendon injuries occur commonly in equine and human athletes and are associated with high re-injury rates due to poor regeneration and scar tissue formation. Equine ESCs survive[1] and differentiate into tenocytes[2] in the injured horse tendon and may provide a source of cells to aid tendon regeneration. Following a tendon injury there is an upregulation of inflammatory cytokines, including IL-1β[3], which may have a negative effect on the function of endogenous tendon cells and exogenous cells applied during therapies.

METHODS: Equine tenocytes from adult, fetal and ESCs were exposed to 17 ng/ml IL-1β. MMP and tendon gene expression was measured using qPCR. Collagen gel contraction in 3D cultures was determined and the storage modulus of the resulting tendon-like constructs was quantified using Dynamic Shear Analysis. The expression of IL1 receptors was determined using qPCR and immunocytochemistry and nuclear translocation of the IL-1β signaling molecule, NFκB was quantified. The ability of IL1 receptor antagonist protein (IL1Ra) to protect tenocytes from the effect of IL-1β was also determined.

RESULTS & DISCUSSION: IL-1β upregulates MMP expression and changes the expression of tendon-associated genes in adult and fetal tenocytes. IL-1β inhibits collagen gel contraction by adult and fetal tenocytes, resulting in tendon-like constructs with a lower storage modulus. A high concentration IL1Ra can protect adult and fetal tenocytes from these effects. In contrast, equine ESC-tenocytes undergo no changes in gene expression or matrix remodeling when exposed to IL-1β. ESC-tenocytes express significantly less of the signaling receptor IL1R1 and more of the decoy receptor IL1R2 and the gene encoding IL1Ra, IL1RN. This corresponds to a lack of nuclear translocation NFκB in ESC-tenocytes following IL-1β exposure.

CONCLUSIONS: Defining the mechanisms by which ESC-tenocytes are protected from inflammation may enable the development of novel pharmaceuticals to protect endogenous adult tenocytes and produce better tendon regeneration to reduce re-injury rates.

INTRODUCTION: Spatiotemporal control on the availability of growth factors is an important factor for controlling the vascularization within an engineered tissue [1]. Therefore, we have designed aptamer-functionalized hydrogel to evaluate their potential for growth factor sequestering, controlled release and study their effect on vessel formation by endothelial cells.

METHODS: The aptamer functionalized hydrogels were prepared via photo-polymerization of gelatin methacryloyl (GelMA) and acrydite functionalized aptamers containing a sequence that is optimized for the binding of vascular endothelial growth factor (VEGF). Irgacure 2959 was used as photoinitiator. The physicochemical properties of these aptamer functionalized hydrogels were evaluated and compared with control samples. To study the programmable release efficiency, the complementary sequences (CSs) were added on the hydrogel system to trigger the growth factor release from the aptamers which was evaluated using ELISA kits. For studying the effect of triggered growth factor release in co-culture system (human umbilical vein endothelial cells (HUVECs) and mesenchymal stem cells (MSCs)), cells were encapsulated within aptamer functionalized hydrogels and the formation of vascular structures was investigated.

RESULTS & DISCUSSION: The results obtained from physicochemical analysis of the aptamer functionalized hydrogels confirmed the aptamer retaining capacity of acrydite functionalized aptamers, in comparison with the control aptamers for as long as 14 days at 37 °C. These results fit well with our hypothesis that the acrydite functionalized aptamers could covalently crosslink within the polymer network whereas control aptamers tend to get just physically entrapped within the hydrogels. The results obtained from the VEGF ELISA experiments showed the triggered release of VEGF from the aptamer functionalized hydrogels in response to CS addition. Without CS addition, these hydrogels could sustain a controlled release for until 10 days. Furthermore, in co-culture experiments, the developed aptamer functionalized programmable hydrogels supported cell viability and the formation of vascular structures by HUVECs and MSCs within the hydrogels for up to 8 days. These results further confirmed the bioactivity of the VEGF molecules after their loading within the aptamer functionalized hydrogels.

CONCLUSIONS: The present study clearly illustrate the beneficial effects of triggered VEGF release on the formation of vascular structures by HUVECs and MSCs in co-culture condition.

INTRODUCTION: Mesenchymal Stromal Cells (MSC)-based therapies are promising for bone regeneration. However, undifferentiated MSC may only exert an inductive paracrine effect without directly producing bone. Here, we developed an injectable product constituted of human bone-forming cells derived from bone marrow (BM)-MSC (ALLO-P2) and tested its bone formation and bone repair capacities in relevant animal models.

METHODS: Human BM cells from healthy volunteer donors were expanded in vitro into undifferentiated MSC (BM-MSC) or differentiated into bone-forming cells (ALLO-P2). Cells were characterized in vitro for the expression of chondro-osteogenic markers by RT-qPCR. Bone formation potential was assessed in vivo, 14 days after a single administration over the calvaria of 12-week old female NMRI-Nude mice, using X-ray and histological approaches. Bone healing capacity was tested in a segmental femoral sub-critical size defect (sub-CSD) model (2 mm, [1]) in female NMRI-Nude mice using X-Ray analyses over time (up to 6 weeks).

RESULTS & DISCUSSION: In vitro, ALLO-P2 cells expressed significantly higher levels of chondro-osteogenic markers such as RUNX2, BMP2, SOX9, MMP13 and ALP than undifferentiated BM-MSC derived from the same donors, indicating their engagement into the chondro-osteogenic lineage. In vivo, a single dose of ALLO-P2 significantly enhanced bone neoformation by about 2-fold, 14 days after a single administration over the calvaria of NMRI-Nude mice compared to BM-MSC (p<0.05). Histological analyses and mouse/human type I collagen double-immunolabelling revealed the presence of an additional bone layer of mixed host and donor origins only in mice administrered with ALLO-P2. Intramembranous ossification was induced along the calvarial surface by both types of cells, but only ALLO-P2 directly generated bone through endochondral ossification. In the segmental femoral sub-CSD model, ALLO-P2 improved fracture repair with a significant reduction of the bone defect size compared to the excipient.

CONCLUSIONS: ALLO-P2, enhanced bone formation and improved bone repair not only by stimulating host bone formation but also by promoting direct bone formation recapitulating endochondral ossification. ALLO-P2 is a potential promising clinical candidate for improving bone regeneration and fracture healing.

INTRODUCTION: Extracellular vesicles (EV) are a promising source of biomarkers for early detection, diagnosis and prognosis of different conditions. In this study, we discussed a method to isolate EVs and assess the dependence of exosome concentrations for 3 different cell lines.

METHODS: Exosome Total Isolation Chip (ExoTIC) is a new technology developed for the efficient isolation of extracellular vesicles (EVs) [1]. Using this unique technology, EVs from different cancer patient clinical samples such as plasma, urine and lavage can be run, and exosomes can be isolated based on their size. ExoTIC is made out of simple materials that cost under a dollar per device and achieves an extracellular vesicle yield ~ 4 - 1,000-fold higher than that with ultracentrifugation (UC), which is a widely-used method for isolating EVs. Here, we studied extracellular vesicles from 5 x 10⁴ – 1 x 10⁶ of AsPC-1 pancreatic cells, 3T3 fibroblast cells and MDA-MB-231 breast cancer cells. We show that EVs from these cell lines can be isolated based on their size using ExoTIC. We used RPMI media with 5% exosome depleted FBS for AsPC-1 and MDA-MB-231, and DMEM medium with 5% exosome depleted FBS for 3T3 cell line. We collected 1.5 mL of media from each cultured cell line samples. A total of 66 samples were prepared. We centrifuged them for 3 minutes at 1200 RPM, and then, filtered the collected media samples through 220nm filters, before running through ExoTIC. We used 30nm and 50nm membranes for EV isolation with ExoTIC. Isolated EV solutions were analyzed using NanoSight, utilizing Nanoparticle Tracking Analysis (NTA).

RESULTS & DISCUSSION: Isolation of EVs from biological samples is fundamental for clinical studies as well as experimental research. We developed and optimized the above protocol for the isolation of exosomes at >30nm and >50nm sizes. The relationship between exosome size based concentration and cell concentration is examined using NanoSight analysis.

CONCLUSIONS: Our results can be used for a wide range of experiments on tissue or cell culture and clinical studies of diseases such as cancer.

INTRODUCTION: Xenogeneic- and serum-free reagents are gaining increasing interest for stem cell culture. Serum contains several molecules that are crucial for initial cell attachment and subsequent survival in vitro, creating a need for added attachment substrates in serum-free culture. Further, the requirement for exogenous attachment proteins also stems from the slow extracellular deposition (ECM) typically observed in dilute culture media. ECM deposition can be accelerated through macromolecular crowding (MMC), a biophysical phenomenon based on the volume excluded by macromolecules in an environment, which accelerates the conversion of procollagen to insoluble collagen in vitro. Therefore, it is hypothesised that MMC in serum-free stem cell culture can accelerate ECM deposition which will support multipotent phenotype maintenance during expansion.

METHODS: Human bone marrow stem cells (BMSCs) were seeded at 25,000 cells/cm² in 24 well plates and were allowed to attach for 24 h. Subsequently, the medium was changed to medium with MMC (carrageenan or Ficoll) and 100 μM L-ascorbic acid phosphate (Sigma Aldrich). Medium without MMC was used as control. Media were changed every 3 days. SDS-PAGE, immunocytochemistry and FACS were conducted after 4, 7 and 10 days. Trilineage differentiation was performed at 21 days.

RESULTS & DISCUSSION: Isolation with different serum and animal component free media maintained the multipotent phenotype of BMSCs, evident by high expression of surface markers CD105, CD73, CD90 and CD44 and low expression of CD31, CD45 and CD146. Animal component free media maintained the spindle shaped morphology BMSCs up to passage 4. Cell viability and metabolic activity were not significantly altered by serum and animal component free conditions (p<0.05). Deposition of collagen type I was significantly enhanced in the presence of MMC in animal component free conditions (p<0.05).

CONCLUSIONS: This indicates the suitability of BMSC-secreted ECM for phenotype maintenance during expansion.

INTRODUCTION: Vascular tissue engineering has emerged from the need to develop functional conduits with similar properties as native vessels. Collagen and elastin are the dominant components of the extracellular matrix (ECM) of this tissue. While collagen is responsible for the stiffness, elastin confers the elasticity. These proteins also regulate vascular smooth muscle cells (SMCs) activity and phenotype. Although several models using collagen gel scaffold were proposed, the importance of elastin incorporation in these structures for cellular activity and final mechanical properties were not investigated. In fact, elastin has been reported to be a missing link in vascular tissue engineering approaches. Herein, the influence of elastin in collagen gels with SMCs was evaluated in terms of cell metabolic function, cell-mediated compaction, expression of key ECM proteins and mechanical properties.

METHODS: Collagen type I was extracted from rat tail tendon and solubilized in acetic acid at 4mg/mL. Genetically engineered elastin-like recombinamers (ELRs) were bioproduced in Escherichia Coli bacteria and dissolved in PBS at 4mg/mL. Human umbilical SMCs were used to prepare cellularized tubular collagen gels with 0, 0.3%, 3%, 30% and 60% in mass of ELR at a cell density of 0.5×10⁶ cells/mL. Alamar Blue viability assay was used to evaluate cell metabolic function. Real-time PCR was performed to evaluate the expression of key proteins by SMCs (collagen, elastin, fibrilin-1, Ki67 and calponin). Immunostaining procedures were applied to observe collagen, elastin and SMCs organization. Finally, the elastic modulus of the tubular samples was evaluated through circumferential stress-relaxation tests. All the analyses were performed after 1, 3, 7 and 14 days of static maturation.

RESULTS & DISCUSSION: The presence of ELR in cellularized collagen gels did not compromise cell viability, showing even an increase in the metabolic activity in the gel containing 30% of elastin. Similarly, this same condition led to lower volumes of gel after maturation suggesting that the cells were more active to remodel the matrix. The elastic modulus increased with higher content of elastin after 14 days of maturation. Real-time PCR support this result as the expression of key ECM proteins, such as collagen were upregulated in presence of 30% and 60% of elastin.

CONCLUSIONS: Altogether, this study demonstrates that the presence of at least 30% of elastin in the collagenous matrix improve SMCs metabolic function, cell-mediated remodeling, expression of key ECM proteins and mechanical properties of the constructs. Interestingly, this condition is the one that closely mimic the native tissue composition.

¹Trinity Centre for Bioengineering, Trinity Biomedical Sciences Institute, Trinity College Dublin, Dublin, Ireland ²Department of Mechanical and Manufacturing Engineering, School of Engineering, Trinity College Dublin, Dublin, Ireland ³Spraybase, Avectas, MaynoothWorks, Maynooth University, Kildare, Ireland.

INTRODUCTION: Electroconductive matrices with defined architectures are warranted to control cell alignment and tissue reorganization of the heart wall after myocardial infraction (MI) [1]. Here, we produced electroconductive scaffolds with defined fibrous architecture by means of melt electrospinning writing (MEW) and the use of polycaprolactone (PCL) and a conductive polymer.

METHODS: We used a commercially available melt electrospinning writing (MEW) apparatus (MELT A-1204-0001-01D, Spraybase, Dublin, Ireland). PCL (80 kDa, Sigma) was blended with the conductive polymer under inert conditions. The electroconductive composite was extruded through a nozzle using gas pressure, a heated melt-head and a voltage field between the spinneret and collecting plate. Another set of PCL alone scaffolds were incubated in the conductive monomer and a dopant solution to deposit onto the PCL fibres. Polymerization of the conductive polymer occurred for 24 h at 4 °C with gentle rotation. FTIR, DSC, conductivity measurements, and SEM imaging were conducted on freshly produced samples and after 2, 7 and 14 days post processing.

RESULTS & DISCUSSION: We characterized the effect of monomer content (1, 5, 10 and 40%), and polymerization time (0.25, 0.5, 0.75, 1, 2, 3 and 4 h) of the polymer composite on electro-conductivity. The highest conductivity was achieved with a polymerization time of 4 h. However, this polymer demonstrated low processability. Highly ordered PCL alone scaffolds were able to conduct the electrical stimulation when coated with the conductive polymer. We measured resistances of 1.8 ± 0.4 kΩ. These electroconductive scaffolds demonstrated conductivity stability after 14 days in PBS. Further, the electroconductive scaffolds demonstrated no cytotoxicity to human MSCs.

CONCLUSIONS: These data illustrate the successful generation of conductive PCL-based scaffolds. Future studies include providing the electrical, mechanical, and topographical cues of the electroconductive scaffolds presented here to induced human pluripotent stem cells (iPS).

INTRODUCTION: Management of critical sized bone defects is a genuine clinical challenge. High-energy combat-related bone defects are manifested in 10-12% of casualties, and 30% of these defects are complicated with osteomyelitis. Temporary and economic costs for treating patients with alterations of reparative regeneration processes, especially in the high-energy mechanism of trauma, the complexity of their social adaptation, justify the need to search for innovative organ-saving technologies of regenerative medicine for bone integrity restoration. Our aim was to develop and assess the clinical effectiveness of transplantation of three-dimensional pre-vascularized tissue-engineered bone equivalent/graft (3D-OPG) for restoration of combat-related bone defects of critical size (ClinicalTrials.gov Identifier: NCT03103295).

METHODS: Bone equivalent transplantation was performed in 47 combat-injured persons with 49 bone defects. Enrolled patients hadn’t previous oncologic diseases reported and possessed circular and tangential critical sized defects of tubular bones and heel bone of various lengths and volume. New bone formation was assessed by X-ray examination and histological analysis. To manufacture 3D-OPG we used partially demineralized allo-/xenogeneic bone (blocks and chips) seeded with autologous cultured cells: BM-MSCs in mix with periosteum progenitor cells (PPCs) and endothelial progenitor cells (EPCs). The quality/identity of cell cultures was assured by flow cytometry (cell phenotype), cytogenetic analysis (GTG-banding), donor and cell cultures’ infection screening (qPCR), functional analysis (cell kinetics, CFU analysis, multilineage differentiation assay), as well as vital FDA / PI combined staining and histological analysis of manufactured 3D-OPG random samples.

RESULTS & DISCUSSION: The casualties were included in a study 8-19 months after injury, due to illustrating the ineffectiveness of conventional surgical methods. All cell cultures had a normal phenotype and karyotype and differentiation potential to orthodoxal lineages. The vital FDA / PI combined staining and histological analysis of 3D-OPG samples showed their regular seeding with viable cells. Histological analysis of 3D-OPG samples taken within adoptive resection surgery 3 months after transplantation shows immature bone tissue formation and graft remodeling. Restoration of the bone defects was observed after 6 months (detected by X-ray examination and histological analysis) [1].

CONCLUSIONS: We discuss an effective method (90.4% effectiveness) for treating the consequences of combat-related limb injuries with use of 3D-OPG. The method allows restoring the integrity of the bone in combat-related bone defects of critical size and to maintain a functional state of a limb.

INTRODUCTION: For clinical applications of stem cell-based therapies, animal component-free culture conditions are required. In previous studies, we assessed the mineralization potential of jaw periosteal cells (JPCs) under supplementation of clinical approved human platelet lysate (hPL) compared to FCS cultivation [1]. In the present study, we performed qualitative analyses of the extracellular matrix (ECM) formed by JPCs under hPL and FCS culture conditions.

METHODS: JPCs were induced osteogenically under FCS and hPL culture conditions. At the end of differentiation, biochemical composition of the formed precipitates was analyzed by Raman microspectroscopy and mechanical properties were assessed by atomic force microscopic (AFM) measurements.

RESULTS & DISCUSSION: By Raman analyses, higher phosphate, lower carbonate content and higher crystallinity of hydroxyapatite minerals were detected under hPL culture conditions. Furthermore, regarding the quality of the collagen network, higher ratios of proline/hydroxyproline and higher collagen cross-linking were detected in hPL-cultured JPCs. Since hPL-supplementation leads to nearly equal production of the precursor protein proline and the mature protein hydroxyproline, these findings might indicate higher elastic properties of the collagen network in contrast to the FCS supplementation. Additionally, cross-linking seems to be higher under hPL culture conditions. When areas of cell monolayers without precipitates were monitored by AFM, higher Young’s modulus of untreated and osteogenically induced JPCs under FCS compared to hPL culture conditions were detected. The opposite was the case for the formed precipitates: under hPL conditions, precipitates formed by JPCs showed significantly higher Young’s modulus than those formed under FCS culturing.

CONCLUSIONS: In the present study, we detected significant differences in the biochemical composition and the mechanical properties of the mineralized extracellular matrix formed by hPL- and FCS-cultured JPCs. The combined technologies represent an optimal tool to assess the quality of in vitro formed bone-like tissue.

INTRODUCTION: Understanding the interaction between cells and their physiological microenvironment has been a crucial topic in cell biology and tissue engineering [1-2]. In cellular microenvironment, natural extra-cellular matrices (ECMs) consist of fibril structures with topographical cues. As the physical architecture of native ECMs could be complex and normally comprised of multiple interaction of global patterns and local topographies, simplification of such effects may improve our understanding in the related governing principles on cell migration dynamics.

METHODS: Low-voltage Electrospinning Patterning (LEP) techniques to fabricate aligned, grid, wavy and loop polymeric fibres depositing on soft elastic substrates. Green fluorescent protein (GFP) transfected cancer cells (MB231) were seeded on such fiber structures, and their migration dynamics were monitored using time-lapse microscopy in a continuous 15-hour time period. Specific focuses were paid to derive the key morphological features for single cell migration.

RESULTS & DISCUSSION: Cells’ morphological responses to the fibril patterns as well as their correlation with the cellular kinetics were quantitatively studied. Cells were able to migrate along the fiber tracks, as well as adapting their morphologies to fit the global patterns and local topologies, especially when cells were trapped in fiber loops. The results are also tested and verified for a novel theoretical model developed for explaining the cell-fibre interactions.

CONCLUSIONS: Cellular behaviors are strongly influenced by ECM architecture and the local interfacing patterns. The results would promote vital application in identifying key morphological parameters and physiological mediators in cell-fibril interactions, as well as predicting cell migration behaviors in various ECM environments.

INTRODUCTION: Regeneration of critically-sized bone defects remains a significant challenge. We have recently identified placental growth factor (PlGF) as a mechanically augmented gene which promotes angiogenesis at high doses and osteogenesis at lower doses [1]. Herein, we sought to functionalize a collagen-hydroxyapatite (CHA) scaffold to deliver PlGF in a dose-controlled manner, with a high burst release to promote angiogenesis followed by a lower sustained release to promote osteogenesis. Furthermore, we aimed to investigate the capacity of this scaffold to promote regeneration of a critically-sized defect in vivo.

METHODS: Recombinant human PlGF-2 (1 µg/mL) was incorporated into alginate microparticles (MPs; 0.5% w/v) and dispersed within CHA slurries pre-loaded with 0, 5 or 10 µg/mL PlGF-2 and freeze dried to form scaffolds termed ‘PlGF-single’, ‘PlGF-dual low’ and ‘PlGF-dual high’, respectively. In vitro evaluations were performed using ELISAs, matrigel angiogenic assays and osteogenic differentiation assays (n=3-4). 7 mm calvarial defects in Wistar rats were treated with scaffolds (n=7-8) and assessed using µCT after 28 days. Statistical comparisons were performed using ANOVA. Significance; p<0.05.

RESULTS & DISCUSSION: MPs were successfully incorporated within scaffolds. PlGF-single scaffolds showed a slow, consistent release whereas both PlGF-dual scaffolds demonstrated initial high burst release profiles followed by lower, sustained releases. When seeded with mesenchymal stem cells, PlGF-dual high scaffolds accumulated significantly more calcium compared to PlGF-free scaffolds (p<0.001). When added to human umbilical vein endothelial cells, elute from PlGF-dual high scaffolds promoted the formation of vessels with a significantly greater number of vascular junctions compared to PlGF-free groups (p<0.001). In vivo, PlGF-dual high scaffolds promoted significantly more bone formation compared to PlGF-free CHA scaffolds (p<0.001).

CONCLUSIONS: A dose-controlled release was achieved by combining the incorporation of PlGF directly within the scaffold, with the encapsulation of MPs, leading to a high burst release followed by a lower, sustained release. The harnessing of this dose-based effect allows for the delivery of pro-angiogenic and pro-osteogenic cues, key aspects of the regenerative process. This work provides a template for a mechanobiology-informed approach to regenerative medicine, by utilizing a therapeutic previously identified by leveraging the differential response of genes to mechanical loading [1].

INTRODUCTION: Hydrogels are used extensively throughout tissue engineering to replicate the role of the Extracellular Matrix [1-2]. Understanding the mechanical properties of these materials is paramount to mimicking this process. However, the experimental quantification of hydrogels under loading from physiological fluid is very difficult. Therefore, this study focuses on quantifying the finite deformation of polyacrylate hydrogels under osmotic loading.

METHODS: Standard imaging techniques, such as confocal microscopy or particle tracking velocimetry, lack the requirements of a system needed to image such a highly dynamic three-dimensional process. Therefore, a novel Lens Free Imaging (LFI) system is developed. LFI combines a CMOS image sensor and partially coherent illumination to capture diffraction patterns of the specimen being imaged. The image is then focused through a variety of post processing algorithms allowing sub-micron resolution over an active imaging area of 20 mm$^2$. This technique can be extended to three-dimensional imaging by adding additional illumination sources. Here, transparent PMMA micro particles are embedded within the hydrogel and are tracked at 15 frames per second over an imaging volume of 80 mm$^3$. As a result, the spatial and temporal coordinates of the micro-particles can be used to mechanically characterize the strain throughout the material.

RESULTS & DISCUSSION: Preliminary results have indicated that the LFI system can track the swelling of these gels. The gels become fully transparent when fluid has permeated to the core. However, the boundary of the gel is still visible. The transparent micro particles can also be tracked after the implementation of a filtered back propagation algorithm.

CONCLUSIONS: The dynamic lens-free imaging of these gels has the potential to be extended to a variety of applications within the tissue engineering field. The advantages include low cost, small geometry, large field of view and dynamic imaging. Future work will concentrate on the dynamic imaging of cell adhesion to a gel matrix.

INTRODUCTION: Cervical Spinal Cord Injuries (SCI) represent more than half of the SCI cases worldwide. Respiratory compromise, as well as severe motor deficits are among the main consequences of cervical lesions. Herein we propose to combine Gellan Gum-based hydrogel modified with GRGDS peptide, together with Adipose Stem Cells (ASCs) and Olfactory Ensheathing Cells (OECs) as a strategy for cervical SCI repair. This approach was previously validated in thoracic and lumbar SCI models [1, 2].

METHODS: A hemisection injury was performed in adult rats, at C2 level. 2×10⁵ ASCs/OECs (1:1) encapsulated in 10 µl of GG-GRGDS were transplanted immediately after lesion at the injury site. Four weeks later, compound muscle action potentials (CMAPs) were performed, while five weeks post-injury diaphragm electromyograms (EMGs) were recorded. In another set of animals, motor and sensorial paradigms such as staircase, grooming and Von Frey tests were evaluated.

RESULTS & DISCUSSION: No differences were observed among groups regarding CMAPs recordings. Rats treated with hydrogel and cells presented increased EMG activity at the ventral and medial portions of the hemi-diaphragm. No differences were observed in forelimb-specific motor tests in any of the paradigms evaluated. Importantly, at the Von Frey test, rats treated with the combinatorial approach demonstrated a reduced hypersensitivity in comparison to non-treated animals.

CONCLUSIONS: These data indicate that the combination of GG-GRGDS hydrogel with ASCs/OECs has beneficial effects in cervical SCI-related respiratory and sensorial deficits.

INTRODUCTION: Polymer capsules exhibit significant potential for therapeutic applications as micro- and nanoreactors, where the bio-chemical reactions of interest are efficiently performed in a spatial and time defined manner due to the encapsulation of an active entity and control over the transfer of reagents and products through the capsular membrane [1]. In this work, we fabricated layer-by-layer (LbL) polymer capsules loaded with MnO\textsubscript{2} nanoparticles and their potential to scavenge H\textsubscript{2}O\textsubscript{2} and attenuate oxidative stress was tested in an in vitro model.

METHODS: Polymer micro- and nanocapsules loaded with MnO\textsubscript{2} were fabricated via the LbL approach using poly(allylamine hydrochloride) (PAH) and poly(sodium 4-styrenesulfonate) (PSS) as polyelectrolytes and MnO\textsubscript{2}-decorated CaCO\textsubscript{3} particles as a sacrificial template. After thorough physicochemical, morphological and functional characterization, polymer capsules were incubated with HeLa cells and their potential to scavenge H\textsubscript{2}O\textsubscript{2} and attenuate oxidative stress was evaluated.

RESULTS & DISCUSSION: Polymer capsules of different sizes [submicron (~600 nm) vs. micronsized (~4 μm)] were satisfactorily fabricated via a precise control of the synthesis conditions of the CaCO\textsubscript{3} template. The presence of MnO\textsubscript{2} nanoparticles within the capsules was confirmed by means of transmission electron microscopy (TEM) and thermogravimetric analysis (TGA). These hybrid polymer capsules efficiently scavenged H\textsubscript{2}O\textsubscript{2} from solution at biologically relevant concentrations (10-50 μM of H\textsubscript{2}O\textsubscript{2}) and did not show any cytotoxic effect towards HeLa cells. Besides, MnO\textsubscript{2}-loaded polymer capsules significantly improved the survival rate of HeLa cells exposed to oxidative stress.

CONCLUSIONS: The developed hybrid polymer capsules represent a promising approach for the treatment of oxidative stress, which is applicable for multiple inflammatory disease targets.

**INTRODUCTION:** Left ventricular (LV) remodeling following myocardial infarction (MI) involves progressive dilatation of the LV cavity, increased LV wall stress, cardiomyocyte hypertrophy and alterations in biochemical and molecular functions leading to heart failure [1]. Stabilization techniques in which the weakened LV wall is mechanically supported have shown promising clinical data [2]. However, the efficacy of these devices remains limited [2]. These results can potentially be explained by the inability of nonresorbable material used in these devices to conform to the LV as it remodels. We hypothesize that a biodegradable passive restraint carrier device will enable a targeted application of a biomaterial-based therapy to the infarcted LV and allow appropriate temporary stabilization, resulting in functional recovery. In this study, a minimally-invasive bioresorbable epicardial patch (SPREADS) was developed by AdjuCor, capable of encapsulating adipose derived stem cell (ADSC) loaded hyaluronic acid (HA) hydrogels to provide mechanical and regenerative support to the weakened LV wall post-MI. Efficacy of SPREADS was assessed in a chronic porcine study.

**METHODS:** Acute MI was induced in pigs (40 kg, Landrace, female) by occlusion of left anterior descending coronary artery for 90 minutes. 14 days post-MI, SPREADS device + HA hydrogel ± ADSCs (n=5) was positioned on the apex by a closed chest subxyphoideal approach and compared to clinical gold standard treatment (GS) (n=5). Heart function was assessed by monitoring the left ventricle ejection fraction (LVEF) via echocardiogram.

**RESULTS & DISCUSSION:** 28 days post-MI (14 days post-treatment) when GS was compared to GS + SPREADS + Gel ± ADSCs we saw a significant improvement in % LVEF (p≤0.001).

**CONCLUSIONS:** We have developed a novel, single-stage strategy to support the weakened myocardial region post-MI using a minimally-invasive, closed chest intervention. We show an improvement in % LVEF with the device ± cells compared to GS alone. The bioresorbable material enables a one-time procedure and the hydrogel encapsulated within the device can be modified to adjust both the mechanical characteristics and degradation rate to better suit stabilization needs of the patient.

INTRODUCTION: Xenopericardial tube grafts are proposed as neoaortic segments to replace infected prosthetic or endovascular grafts [1]. To prevent graft rejection and biodegradation, xenogenic biomeshes are usually provided in the decellularized and chemically cross-linked form. However, the stiffness of these products is an order higher compared to the native arteries (Young’s Modulus ∼8-12 MPa) [2]. In our work, we describe an approach to tailor elasticity of chemically cross-linked decellularized bovine pericardium (DBP) towards the application in vascular reconstruction.

METHODS: First, bovine pericardium was decellularized using a modified alkaline treatment protocol. Next, DBP was treated with three different cross-linkers, namely ethylene glycol diglycidyl ether (EGDE), 1-ethyl-3-(3-dimethylaminopropyl) carbodiimide (EDC) and genipin; and then freeze-dried for further scCO2 extraction. The acquired samples were thoroughly characterized by mechanical trials (nanoindentation, tensile testing), cytotoxicity (MTT-test), biodegradability (collagenase A digestion) and ultrastructural (scanning electron microscopy and two-photon laser scanning microscopy) studies. Finally, the effect of scCO2 extraction during 3 h on the sample properties was estimated in static and dynamic modes. All tests were performed in a liquid at 37°C.

RESULTS & DISCUSSION: We demonstrated that the cross-linking chemistry strongly influences the biodegradation rate, but the values do not alter under scCO2 extraction. The highest collagenase stability was achieved by EGDE treatment, and the lowest – by EDC. Scanning electron microscopy did not reveal structural derangements, as well as two-photon confocal laser scanning microscopy indicated the preservation of second harmonic generation produced by collagenous constituents. No effect of scCO2 extraction on the cytotoxicity level was observed. However, Young’s Modulus reduced after the scCO2 extraction independent of the extraction mode as was demonstrated by both nanoindentation and tensile testing.

CONCLUSIONS: Collectively, these data clearly illustrate the beneficial effect of scCO2 extraction on elastic properties of the biomeshes as candidates for vascular reconstruction with reduced hypertension.

INTRODUCTION: Intracellular bacterial infections are notoriously difficult to treat, in part due to poor membrane permeability and intracellular bioavailability of antibiotics. They can arise as a result of the implantation of biomaterials [1]. Current treatment options involve high doses of antibiotics for sustained periods of time, therefore contributing to the issues of antibiotic resistance [2]. Antibiotic encapsulation within nanoparticles, such as polymersomes (PMs), may provide an answer to this challenge by promoting intracellular uptake and targeted drug delivery. In this study we tested the hypothesis that polyethylene oxide-polycaprolactone (PEO-PCL) PMs can encapsulate the antibiotic rifampicin, with a view to treating intracellular infections in the future.

METHODS: PMs were prepared by dissolving 6 mg of the amphiphilic di-block copolymer PEO-PCL into 0.4 ml of dimethylformamide (DMF). Polymer solution was then added dropwise into phosphate buffered saline (PBS), under stirring, to facilitate the self-assembly of PMs by nanoprecipitation. To determine loading efficiency, rifampicin was passively incorporated at concentrations ranging from 0 – 20 mg/ml. Samples were dialysed, and the resulting PM-antibiotic concentrations determined using UV-vis spectrophotometry. To assess PM-antibiotic stability UV-vis readings were taken at various timepoints across a 14-day dialysis period.

RESULTS & DISCUSSION: As the level of rifampicin loaded during PM preparation was increased, there was a concomitant proportional increase in the level of rifampicin successfully encapsulated within PMs. Encapsulation was linear with respect to loading concentration up to 10 mg/ml, where the highest level of drug encapsulation was achieved. PM-rifampicin preparations were stable for at least 14 days with no changes in hydrodynamic radius, as measured by dynamic light scattering, 88.5 nm ± 1.9. Antibiotic release and PM stability studies showed that the PM-rifampicin preparations had 8.5 μg/ml retained at Day 14 in bulk suspensions, equivalent to an estimated local nanoparticle concentration of 7 mg/ml.

CONCLUSIONS: Rifampicin can be successfully encapsulated into PEO-PCL PM nanoparticles, and retained for at least 14 days. We hypothesise this is due to the hydrophobic nature of rifampicin and its stabilisation within the hydrophobic membrane of the PMs. Future work will assess the efficacy of these nanoparticles on the killing of intracellular Burkholderia thailandensis.

ACKNOWLEDGEMENTS: We are grateful to DSTL, EPSRC, and the Institute for Life Sciences, Southampton for funding.

INTRODUCTION: Conventional cultures have been proven inadequate to provide sufficient levels of oxygen and nutrients to the interior of the scaffolds, and mechanical stimulation to the cells. On the contrary, dynamic cultures realized with the aid of microfluidics reflect more appropriately the in vivo environment of cells in tissues [1]. The purpose of the present work is to fabricate a novel microfluidic platform for the study of the combined effect of fluid shear forces and culture substrate morphology on cell proliferation and directionality [2].

METHODS: The microfluidic system is composed of a pressure controller, a flow sensor and a chamber containing the microstructured substrates with the cells. A Yb:KGW laser was used (170 fs pulse duration, 1 kHz repetition rate, 1026 nm wavelength) to fabricate the polymeric microstructured substrates. 25000 Schwann (SW10) cells were seeded in PET coverslips to perform the static and dynamic cultures.

RESULTS & DISCUSSION: PET coverslips were ablated by the femtosecond laser at a constant fluence of 11.9 J/cm², scan velocity of 7 mm/s and a xstep of 50 μm to fabricate the microgrooves [3]. The cytoskeleton of the SW10 cells was elongated along the direction of the microgrooves whereas a random orientation observed on the flat PET. By applying a flow rate of 50 μL/min, cells oriented along the direction of the microgrooves and parallel to flow. Interestingly, cells oriented parallel to flow on the flat PET. An increased cell length was noticed under flow conditions (50 μL/min) compared to static. Finally, a further enhancement of cell length was observed under flow conditions combined with the microgrooves (Figure 2).

CONCLUSIONS: Our results indicate the ability to engineer cell alignment in vitro that could be potentially useful in the field of neural tissue engineering.

ACKNOWLEDGEMENTS: Financial support was received from State Scholarships Foundation (IKY) and Onassis Foundation.

INTRODUCTION: Formative biofabrication is an alternative strategy for tissue constructs engineering applying large preformed multicellular fabrication units, tissue spheroids (TS). By this approach engineered tissue is assembled quickly, within 30-45 seconds, and scaffold-free. We are developing a new scaffold-free approach as an alternative or addition to scaffold-based one. In this approach TS were patterned and hold together by physical forces or physical fields. Magnetic field as well as acoustic field provide temporal and removable support and it could be considered as a new form of scaffold. To escape a possible confusion, we propose to call this new type of temporal support based on employment of physical fields as a scaffold.

METHODS: TS were prepared from sheep and human primary chondrocytes, chondrocytes immortalized line SW1353, rat thyrocytes using non-adhesive technology. Biofabricated TS were used for magnetic, acoustic and acoustic-magnetic levitation. Magnetic levitation was performed applying an experimental custom-made magnetic printer in presence of different Gd³⁺ gadolinium concentrations, depending on gravity conditions and magnetic field strength. Acoustic and acoustic-magnetic levitation was performed on custom-made experimental devices too.

RESULTS & DISCUSSION: TS of standard geometry were applied for magnetic levitation. Our experiments confirmed that relatively weak magnetic fields allow quick levitational assembly of tissue spheroids only in the presence of high 50 mM Gd³⁺ concentrations which represents borderline toxicity state. We hypothesized that employing higher gradient magnetic field we could decrease Gd³⁺ gadolinium concentration and perform TS assembly at non-toxic Gd³⁺ concentration in paramagnetic medium. TS magnetic levitational assembly was performed at The European High Magnet Field Laboratory and showed that employing 22 Tesla we were able to decrease Gd³⁺ gadolinium concentration down to 0.8M. Another approach involves the use of space microgravity conditions. We developed a magnetic bioprinter to produce cartilage construct and rat thyroid gland construct in Space applying 0.8mM, 10mM and 50mM Gd³⁺ concentrations.

CONCLUSIONS: 3D tissue constructs have been biofabricated from TS in paramagnetic medium at different gravity conditions and various Gd³⁺ concentration. We report for the first time a successful rapid assembly of 3D tissue engineered construct using scaffold-free, label-free and nozzle-free magnetic levitation of TS in gravity and in zero gravity conditions in Space. In microgravity conditions the tissue construct was assembled at 10mM, 50Mm Gd³⁺ concentrations but not at 0.8mM one. These data provide a proof of concept for new strategies in tissue engineering. Formative biofabrication enables rapid assembly of various tissues and organs. Additionally, the systematical investigation of the scaffold-free and label-free acoustic and acoustic-magnetic levitation has been started as additional potential technologies.
TRPV4 inhibition reduces stretch-induced inflammation in human intervertebral discs

INTRODUCTION: Low back pain (LBP) and degenerative disc disease (DDD) profoundly affect the health and economics of our society. Mechanical loading and inflammation are interacting causes of DDD. Cyclic stretching of intervertebral disc (IVD) cells was shown to induce secretion of inflammatory mediators [1]. However, little is known about the underlying mechanisms. Recently, the transient receptor potential vanilloid 4 (TRPV4) channel was associated with reduced osmolarity and pro-inflammatory cytokines in the IVD [2]. Nevertheless, its role in IVD mechanotransduction remains to be fully elucidated. The aim of this study is to test whether stretch-induced inflammation of IVD cells is regulated by TRPV4.

METHODS: Primary human annulus fibrosus cells (n=3-4 donors) were seeded on fibronectin-coated PDMS chambers and cyclically stretched for different durations (1 to 24 hours) at 20% strain and 1 Hz frequency on a commercial bioreactor (STB-140-10, Strex). In TRPV4 inhibition experiments (n=4), cells were stretched for 1 hour with/without the specific TRPV4 antagonist GSK2193874 at different concentrations (20 to 500 nM). Gene/protein expression were quantified by RT-qPCR/ELISA. Calcium flux was analyzed by live imaging with the Fluo-4AM dye and activation of MAP kinases (p-38, JNK, ERK) was tested after 15 min stretching (n=3) by Western blot.

RESULTS & DISCUSSION: Gene expression of IL6, IL8 and COX2 was significantly upregulated by 1 hour stretching compared to controls, and decreased with longer durations. Stretch-induced upregulation of IL6 and COX2 mRNA expression was reduced by GSK2193874 (Fig.1). On the protein level, PGE2 was only slightly increased by stretching and reduced by TRPV4 blocking. Stretching caused calcium influx and phosphorylation of p-38, JNK and ERK compared to controls, and p38 activation was reduced by GSK2193874.

CONCLUSIONS: Stretch-induced inflammation may be mediated at least in part by TRPV4. TRPV4 may thus constitute a potential therapeutic target to tackle DDD and LBP. Current work includes experiments with CRISPR/Cas9-based TRPV4 knockout cells.

Dexamethasone drives early osteogenic differentiation by modulation of SOX9 and PPARG expression
E. Della Bella, V. Basoli, M. Alini, M.J. Stoddart
Presenting Author: Elena Della Bella, elena.dellabella@aofoundation.org

INTRODUCTION: Dexamethasone is widely used in protocols for osteogenic differentiation and it has been associated with an increase in RUNX2 expression. However, it also inhibits osteocalcin expression and terminal differentiation of osteoblasts. The present study aims to clarify the role of dexamethasone during early stages of osteogenic differentiation and to improve currently used protocols with a potential for a higher clinical translation of in vitro results in the field of bone research.

METHODS: Human bone marrow-derived mesenchymal stromal cells were obtained from 4 donors with full ethical approval and induced towards osteogenic differentiation. Differentiation medium was DMEM 1 g/L glucose with 10% FBS containing 50 µg/mL ascorbic acid 2-phosphate and 5 mM beta-glycerol phosphate. Dexamethasone (dex) was used at 0, 10, or 100 nM for the first week of induction, then different combinations of 0 or 10 nM were used thereafter. Osteogenic gene expression was assessed after 7 and 21 days, while mineral deposition was analyzed at day 21.

RESULTS & DISCUSSION: Day 7 gene expression analysis showed no effect of dex on RUNX2, RUNX3, or SP7. However, dex inhibited SOX9 expression and upregulated PPARG in a dose-dependent manner. The RUNX2/SOX9 ratio at day 7 positively correlated with Alizarin red staining at day 21, even when dex was reduced to 0 or 10 nM after the first week.

CONCLUSIONS: Preliminary results suggest that the outcome of differentiation is mainly decided within the first week of induction. Comprehensive analysis of RUNX2, SOX9, and PPARG expression suggested that, while RUNX2 levels are constant despite increasing concentrations of dex, regulation of the other transcription factors is more influential on differentiation. In particular, the results showed an inverse correlation between early SOX9 expression and mineralization at day 21, supporting the hypothesis that a drop in SOX9 levels is the main event driving osteogenesis, potentially by unleashing inhibition of RUNX2.

INTRODUCTION: The availability of primary cells present in pathological conditions is often very limited due to stringent ethical regulation and patient consent. One such condition is chronic wounds, where dermal fibroblasts show a deficient migration. In vitro models with cellular tools that mimic the in vivo scenario would be advantageous to test new tissue-engineered therapies for these challenging wounds. Since the availability of primary dermal fibroblasts present in chronic wounds is restricted and their “shelf-life” limited due to increased senescence, our aim was to engineer human dermal fibroblasts with impaired migration using synthetic RGD peptides.

METHODS: First, the study was carried out on 3 different 2D surfaces representative of the materials used to develop tissue-engineered dermal scaffolds: hydrophilic synthetic polymeric surface, and fibrinogen and gelatin surfaces. Different variables and RGD peptide concentrations were tested. Cell attachment, migration, and integrin expression were studied. Next, RGD treated cells were seeded in commercially available, clinically used, collagen-based 3D dermal scaffolds (Integra® and Matriderm®) and their attachment and migration studied. The mechanism of action of both scaffolds is through integrin ligands.

RESULTS & DISCUSSION: Results on 2D surfaces showed cell attachment is reduced in a concentration dependent manner. Cells cultured on gelatin surfaces looked the most spread and obtained overall the least reduction in cell migration. Expression of integrins was not affected and the components of the migration pathway were not altered by the RGD peptides. Results in 3D scaffolds showed that the concentration of synthetic RGD peptides necessary to impair migration of dermal fibroblasts should be tailored to the number of RGD sites present in the 3D matrix.

CONCLUSIONS: The concentration of synthetic RGD peptides necessary to impair migration of dermal fibroblasts should be tailored to the particular surface/material and cell population used. The described technology could be translated to other cell types including established cell lines. A wide range of synthetic peptides exist, which differ in the amino acid sequence, thus increasing the possibilities of this technology [1].

INTRODUCTION: In recent years, bi- and triphasic osteochondral (OC) scaffolds have been investigated as an alternative to traditional procedures. However, the issues of delamination, less accurate graded structure, as well as poor mechanical properties are limiting their application. These actual challenges form the focus of this work, which aims to design and develop novel 3D scaffolds in order to best mimic the multilayered nature of OC tissue in its integrity and function.

METHODS: A 3D-Bioplotter (EnvisionTEC Germany) was used to produce cylindrical scaffolds with strand thickness of 400 µm and different inner patterns. Three powder-derived formulations (combined with a solvent-free approach) were investigated: poly-\(\varepsilon\)-caprolactone (PCL), PCL/hydroxyapatite (HA) and PCL/strontium-doped (HA) at different ratios (see Table 1). The effect of compositional and architectural variations of the resulting bioplotted scaffolds was analysed in terms of physico-chemical (FTIR, TGA, SEM, contact angle and micro-CT) and mechanical properties, as well as biological behavior (cytotoxicity, attachment and proliferation).

RESULTS & DISCUSSION: The ceramic phase slightly affected the printing temperature of the formulations (140°C composites vs 130°C PCL alone). TGA and FTIR analysis confirmed the presence of HA in the raw powders as well as extruded materials, demonstrating a homogenous mixing of the two phases. 3D bioplotted scaffolds exhibited a range of customizable hierarchical structure (see Fig.1) and mechanical properties (Young's modulus in the range 23.27±2.2÷117.73±7.1 MPa) appropriate to match those of OC tissue layers. SEM analysis showed how the presence of the ceramic phase affected the scaffold’s surface roughness, which in turn enhanced the hydrophilicity as well as the in vitro behavior in contact with Y201 cells.

CONCLUSIONS: The use of a 3D-Bioplotter revealed promising to manufacture custom design, OC-like substitutes with a unique multilayered structure. Also, the inorganic phase favored the development of 3D scaffolds with greater biomechanical stability and biocompatibility.

INTRODUCTION: Tissue related O₂ - “physiological” hypoxia, is considered as an important physical governor of multipotent mesenchymal stromal cells (MSC) fate in local tissue milieu. Here we examined the extracellular matrix (ECM) deposition and hypoxia-regulated gene expression in MSCs under “physiological” hypoxia.

METHODS: Human adipose tissue MSCs were permanently expanded at ambient (20%) and “physiological” hypoxia (5%) O₂. Collagen and noncollagen ECM proteins were stained with Sirius Red F3BA and Fast Green FC, respectively and then quantified by colorimetric analyses. Gene transcription profile was examined with Illumina global gene expression analysis and verified with RT-PCR.

RESULTS & DISCUSSION: Histochemical staining with subsequent colorimetry, did not reveal difference in deposition and amount of collagen and noncollagen proteins in ECM of MSCs at 5 vs 20% O₂. According whole genome profiling, among 86 ECM-related genes only 11 were upregulated. “Core” matrisome (collagens, glycoproteins, proteoglycans) comprised 70% of ECM genes, while the other included proteases and ECM-associated molecules. Using a database of hypoxia-regulated proteins [3] the 60 corresponding genes have been identified. The vast majority of those genes were downregulated: a half among of “core” and most of all matrisome-affiliated (Tabl. 1). RT-PCR analysis of several genes encoding ECM molecules of different groups revealed changes of FN, COMP, MMP1, MMP2, PLAU, TIMP3, TGFB, SPP1 transcription coincided with the results of full-genome analysis.

CONCLUSIONS: MSCs demonstrate the substantial ECM accumulation both at ambient O₂ and "physiological" hypoxia. The shift in the ECM-associated genes transcriptomic profile suggests that in case of tissue damage these cells will be more "predisposed" for the realization of reparative properties, such as migration and proliferation.

INTRODUCTION: Prerequisite for successful clinical use of autologous adipose tissue-derived cells is the highest possible regenerative potential of the applied cell population, the stromal vascular fraction (SVF). Current isolation methods depend on high enzyme concentration, lysis buffer, long incubation steps and mechanical stress resulting in single cell dissociation from their natural microenvironment. The aim of this study was to limit cell manipulation and obtain a derivative comprising therapeutic cells (Microtissue-SVF) without dissociation from their natural extracellular matrix by employing a gentle GMP-grade isolation with low enzyme concentration.

METHODS: Within this study, our optimized Standard-SVF isolation protocol was adapted resulting in SVF cells protected within their extracellular matrix and analyzed regarding structure, yield and viability, presence of regenerative cells and subpopulations, trophic factor release, vascularization, trilineage differentiation potential and integration after intramuscular injection into nude mice.

RESULTS & DISCUSSION: Microtissue-SVF yielded higher numbers of viable cells compared to standard isolation and a minimal content of dead cells. It comprised stromal tissue compounds (collagen, glycosaminoglycans, fibroblasts), capillaries and vessel structures (CD31\textsuperscript{+}, smooth muscle actin\textsuperscript{+}). A broad range of cell types were identified by surface marker characterization including mesenchymal, hematopoietic, pericytic, blood and lymphatic vascular and epithelial cells. Subpopulations such as supra-adventitial adipose-derived stromal/stem cells and endothelial progenitor cells were significantly higher in Microtissue-SVF (Figure 1) corroborated by significantly higher potency for angiogenic tube-like structure formation in vitro. Microtissue-SVF showed the characteristic phenotype and tri-lineage mesenchymal differentiation potential in vitro according to the ISCT/IFATS, as well as an immunomodulatory and pro-angiogenic secretome. In vivo implantation of Microtissue-SVF combined with fat demonstrated successful graft integration in nude mice.

CONCLUSIONS: In this study, we present a fast and gentle isolation by minor manipulation of liposuction material, achieving a therapeutically relevant cell population with high vascularization potential and immunomodulatory properties still embedded in a fraction of its original matrix.

ACKNOWLEDGEMENTS: We would like to acknowledge Dr. Hajnal Kiprov and Dr. Matthias Sandhofer for providing liposuction material and valuable discussion. This work was funded by a grant from the Austrian Research Promotion Agency (FFG) (Bridge1 programme, grant No.846062).
INTRODUCTION: There is a demand for replacing vascular conduits in some clinical situations, such as vascular occlusions or aneurysms. Tissue engineering has focused on developing tubular structures similar to the native structure of blood vessels: endothelial cells (EC) parallelly aligned to the vessel in the inner layer and smooth muscle cells (SMCs) perpendicularly aligned to the vessel in the outer layer. The aim of this work is to mimic the architecture of a blood vessel through a multilayered hollow hydrogel-based fiber.

METHODS: The hollow hydrogel-based fiber was obtained through an extrusion technique, using a triple core-shell nozzle. The composition was: i) alginate with gelatin or collagen in the shell; ii) collagen in the middle-core; iii) pluronic in the inner-core. Once the multilayered fiber was formed, pluronic was removed to obtain a hollowed tubular structure. Hydrogel compositions were optimized to maintain geometrical stability and to allow the encapsulation of human umbilical vein endothelial cells (HUVEC) in the core and human SMCs in the shell. Different cell concentrations and ratios were studied to validate the elongation, proliferation and alignment of the cells and was compared to the native conformation.

RESULTS & DISCUSSION: Preliminary results with non-hollowed core-shell fibers showed that HUVEC were able to elongate, proliferate and align parallel to the direction of the fiber. The optimal HUVEC concentration for cell elongation was around 2x10^6 cells/mL. With the hollowed core-shell fibers, 5 mg/mL collagen maintained the tubular structure once pluronic was removed and HUVEC cells were also able to maintain its parallel alignment in the fiber direction. However, the highest concentration tested (5x10^6 cells/mL) was not enough to cover all the fiber. The shell composition was then optimized mixing 1,5-3% alginate with collagen at low concentrations, allowing the encapsulation of 5x10^6 cells/mL of hSMC, showing that the composition induced the elongation of most hSMC. However, their orientation was completely random.

CONCLUSIONS: These preliminary results showed similarities with the native structure of blood vessels and the survival of HUVEC with the right orientation. Although hSMC could also survive, further experiments are needed to optimize the hSMC alignment and proper cell concentrations to completely cover the hollow fiber. Furthermore, co-cultures need to be further explored to analyze the possible cross-talks.

INTRODUCTION: In situ vascular tissue engineering (TE) is rapidly moving towards clinical application, however, early stenosis and aneurysm formation remain prevalent occurrences. These complications are often attributed to a mismatch between scaffold properties and hemodynamic loading, i.e., cyclic stretch and shear stress. Here we aimed to understand the relative roles of hemodynamic loads on the regeneration of vascular tissues using a custom-made bioreactor that allows shear stress and cyclic stretch to be effectively decoupled.

METHODS: Human vena saphena cells (HVSCs) and primary monocytes (MQs) were seeded in electrospun polycaprolactone-based scaffolds using fibrin. The constructs were subjected to shear stress ($\tau_w$; 1 Pa), cyclic stretch ($\lambda$; 1.05), or combined loads (1 Pa $\tau_w$+1.05 $\lambda$). After 3 and 20 days, samples were analyzed for cell phenotype, inflammatory state, and matrix G&R by a wide range of analysis techniques (qPCR, tissue assays, immunohistochemistry, mechanical tests, zymography, ELISA).

RESULTS & DISCUSSION: Both cell types remained viable throughout the duration of the experiment. Cyclic stretch stimulated HVSC proliferation and neotissue formation and reduced the secretion of pro-inflammatory cytokines. Shear stress, on the other hand, attenuated cyclic-stretch-induced tissue growth, but enhanced MMP1- and TIMP1-mediated collagen remodeling, which are reflected in the mechanical properties of the constructs. The combination of both loads resulted in a synergistic increase in IL-10 secretion and suppression of HVSC contractile phenotype.

CONCLUSIONS: Together, the results suggest that shear stress and cyclic stretch differentially act as regulating factors during early in situ regeneration. These insights are critical for understanding and improving the long-term clinical performance of in situ tissue engineered blood vessels.

Figure 1: A): scaffolds containing MQs and HVSCs are exposed to either shear stress, cyclic stretch, or a combination thereof. (B): Elastic modulus in circumferential direction and total hydroxyproline (HYP) content.

INTRODUCTION: Fibril topography is a significant environmental cue that the extracellular matrix (ECM) provides in tissues [1]. Existing work has explored the effect of surface topography at single cell level [2]. We developed a 3D printing platform capable of patterning suspended fibres in 3D, which mimic the resolution of the large fibril components of the ECM. Here, we show the effect of topographic features in 3D space, interfacing cell aggregates. Our results demonstrate fibres creating a local topographic effect whilst steering global spheroid morphology.

METHODS: Human glioblastoma cell aggregates (U87) were seeded on suspended fibre devices. Devices consist of suspended electrospun gelatin fibres patterned with low voltages (100-130V), around 1-10 μm in diameter, suspended over 3D printed PLA support structures. Cell aggregates were cultured on four different suspended fibre patterns, with media refreshed every 48 hours. The different spheroid morphologies were stained for viability and cell response was measured over a spatial distribution after 1, 3 and 10 days of culture.

RESULTS & DISCUSSION: The topographic guidance and biochemical similarity to collagen provided by suspended fibre scaffolds encourages cell strings to form rapidly, developing into dense suspended cell structures. The low fibre stiffness enables cells to perform non-axial deformation on the scaffold and cell-cell interaction encourages clusters of cells to fuse. Cell strings are highly viable and larger spheroids are viable at the surface but beyond the typical thickness, internal cells become necrotic. Despite the ability of the cells to remodel the scaffold, the overall morphology of the suspended cell structure reflects the in-plane fibre patterns.

CONCLUSIONS: This study demonstrates suspended fibre architecture for guiding self-assembly of cells cultured in 3D, such as [3]. Suspended fibre architecture influences spheroid morphology and growth characteristics. Topography guided 3D cell culture is still largely unexplored, with significance in cancer research.

3Department of Oral Cell Biology, Academic Centre for Dentistry Amsterdam (ACTA), University of Amsterdam and Vrije Universiteit, Amsterdam, The Netherlands

INTRODUCTION: Validation of novel therapies against cancers, such as melanoma, requires models that reflect the human physiology and immune response. The current use of humanized animal models is associated with high costs and low prediction of success in clinical trials, while two-dimensional (2D) cultures fail to reflect the complex tumor microenvironment. There is thus a need for improved three-dimensional (3D) organotypic in vitro melanoma models to facilitate development of therapies.

METHODS: Melanoma reconstructed human skin (Mel-RhS) models were constructed by co-seeding Sk-Mel-28 melanoma cells and keratinocytes onto a fibroblast-populated dermal equivalent, followed by culture in air-lifted conditions for up to six weeks. (Immuno)histochemical staining was used to identify tumor cells and compare the developed Mel-RhS model to melanoma patient material. Culture supernatant was used to detect cytokine secretion by ELISA and to assess changes in the expression of surface markers during monocyte to monocyte-derived dendritic cell (mo-DC) differentiation by flow cytometry.

RESULTS & DISCUSSION: Tumor nests were observed to develop over time at the epidermal-dermal junction and to spread towards the dermis, disrupting the basement membrane. We also observed increased secretion of cytokine IL-10 in Mel-RhS compared to healthy controls. Of note, Sk-Mel-28 cultured in 2D monolayers did not produce detectable IL-10 levels. Supernatant collected from Mel-RhS stimulated differentiation of mo-DC into M2-like macrophages.

CONCLUSIONS: Features of the Mel-RhS resemble the initial stages of invasive melanoma in humans. In addition, the ability of the Mel-RhS culture supernatant to promote a tolerogenic M2-like phenotype in mo-DC cultures is consistent with a switch towards a more immunosuppressive tissue microenvironment. Collectively, this data demonstrates that the developed melanoma model has the potential to be used for research on melanoma development and invasion, in the setting of an immune competent skin microenvironment. In the future, the model may also provide an in vitro tool for preclinical testing of novel therapeutics, bringing us one step closer to personalized medicine.

**INTRODUCTION:** Bioactive glasses (BG) are attractive materials for bone tissue engineering due to their bioactivity and osteoinductivity. We report the synthesis and characterization of novel silicate–based bioactive glasses (S-BG) with composition of 49.9-52% SiO₂, 23-23.7% Na₂O and 22.8-23.3% CaO (%wt). The biocompatibility, osteogenic and angiogenic properties of S-BG particles were analyzed in vitro with human adipose-derived mesenchymal stem cells (AdMSCs) and human osteoblasts (OBs). Angiogenesis was further tested in vivo in a zebrafish embryo model.

**METHODS:** Glass synthesis was performed by melt quenching. Elemental composition and identification of the S-BGs crystalline phases was performed by X-ray. Thermal analysis was performed by TG-DTA. The bioactivity of produced S-BGs was performed by immersion in Simulated Body Fluid, and subsequent mineral deposition was analyzed by SEM. S-BGs biocompatibility was evaluated by means of MTT and LDH using AdMSCs and OBs. Proliferation was assessed in both cell types by PicoGreen. Furthermore, gene expression was evaluated by RT-PCR. VEGF production was investigated by ELISA, and using a zebrafish embryo model. The best performing S-BG was selected and glass particles were incorporated into a polycaprolactone solution 10% (w/v). PCL/S-BG scaffolds were fabricated by additive manufacturing, and evaluated in vitro for biocompatibility, osteogenic and angiogenic properties using AdMSCs.

**RESULTS & DISCUSSION:** S-BGs were biocompatible and induced the deposition of a mineralized matrix and the expression of osteogenic and angiogenic markers (RunX2, ALP, Osteocalcin, Osteopontin, Collagen I and VEGF). VEGF was secreted in vitro. When tested in a zebrafish embryo model, the solutions containing the S-BG ions showed abundant vessel formation that was similar to the positive controls (i.e. treated with bFGF). PCL scaffolds doped with 10%wt glass showed high porosity (76%) and pore interconnectivity. The incorporation of S-BG particles increased AdMSCs proliferation compared to plain PCL scaffolds, indicating improved biocompatibility. Finally, S-BG incorporation improved the scaffolds’ osteogenic and angiogenic properties by increasing mineral deposition and inducing relevant gene expression as well as VEGF protein secretion.

**CONCLUSIONS:** Collectively, these data clearly illustrate P₂O₅-free BG particles as attractive for bone engineering applications with relevant angiogenic properties.

INTRODUCTION: Numerous reports have indicated a strong dependence of cell adhesion and proliferation on the scaffold microstructure. Bioengineered artificial extracellular matrices (aECMs) containing glycosaminoglycans (GAGs) with a specific sulphation pattern have been found to regulate cellular responses during healing process [1]. Here we evaluate the synergistic effect of microstructure (monomodal vs. bimodal porosity) and aECM surface modification of poly(L-lactide-co-glycolide) (PLGA) scaffolds on the osteogenic differentiation of human mesenchymal stem cells (hMSCs).

METHODS: PLGA bimodal scaffolds were produced by solvent casting/porogen leaching with the use of salt and PEG as porogens [2]. The scaffolds were coated with aECMs containing collagen type I and highly sulphated hyaluronic acid (coll/sHya) and were characterised by µCT, SEM-EDX and compression test; content of coll and sHya was measured by Sirius red and toluidine blue, respectively. hMSCs were seeded at 45,000 cells/scaffold and cultured up 28 days. Cell adhesion, proliferation (LDH), differentiation (ALP activity, mineralization and gene expression by real-time PCR) were evaluated.

RESULTS & DISCUSSION: The application of two porogens resulted in bimodal pore distribution within the PLGA scaffolds as shown by SEM and micro-CT. Two types of pores with diameters 400 – 600 µm and 2 – 20 µm were obtained. The scaffolds were successfully coated with a homogenous layer of aECM. In vitro study showed that presence of bimodal pore distribution in combination with collagen/sHya did not significantly influence hMSC proliferation and early osteogenic differentiation compared to scaffolds with monomodal pore distribution. However, it enhanced mineralization as well as the expression of Runt-related transcription factor 2 (RUNX-2), osteopontin and bone sialoprotein II.

CONCLUSIONS: As a result PLGA scaffolds with bimodal pore distribution modified with collagen/sHya can be considered as prospective material promoting bone regeneration.

INTRODUCTION: The environment transmits forces through the cell cytoskeleton, inducing nuclear mechanotransduction. We developed an innovative microstructured 3D culture scaffold named “nichoid” that provides a geometric constraint to adhering cells, favoring maintenance of the stemness of mesenchymal stem cells (MSC) [1]. Here we want to prove that the nichoid affects not only cell adhesion, but also some aspects of cell migration.

METHODS: Rats bone marrow MSC were seeded in 3D nichoids and on flat glass coverslips (controls). Cells were processed for immunofluorescence analysis by using the fluorescent antibody anti-vinculin and the fluorescent dye phalloidin-FITC and Hoechst33342 to stain actin cytoskeleton and DNA. In order to study cell migration, MSC nuclei were stained by Hoechst-33342 fluorescent probe. Z-stack (1 m depth) and time lapse (one acquisition every 20 min for 6h) were acquired by a confocal microscope. The software ImageJ and Origin Pro were used to analyze images and to quantify cell displacements and path.

RESULTS & DISCUSSION: Our results show that the structure of the 3D-nichoid affects cell migration. MSC grown in the nichoid have a migratory capability reduced by 33% compared to controls in terms of displacement and total distance covered (so-called path). Nevertheless, MSC adhering to the nichoid lateral walls showed a mobility comparable to flat controls. These results were related to the cell morphology: immunofluorescence measures revealed that MSC in the nichoid had focal adhesions reduced by 19% in number compared to controls. In addition, the cell cytoskeleton was modulated by interaction with the nichoid scaffold: in MSC adhering in the nichoid, the cytoskeleton was mainly composed by cortical actin networks, while in cells on flat controls we observed thick stress fibers also inside the cell cytosol, that likely transmitted higher forces from the cell periphery to the nucleus.

CONCLUSIONS: Our results show how the properties of the nichoid scaffold affect drastically the migratory cell behavior. In the nichoid, the cell capability to migrate is reduced by the absence of a flat substrate for cell adhesion. We hypothesize that such motion constraint is a key feature causing stemness maintenance in the 3D nichoid scaffold and we plan to further investigate this effect on the expression of motility-related genes.

INTRODUCTION: Xenografts are commonly used in dental patients requiring bone volume restoration and regeneration¹. However, common origin of procurement & processing does not guarantee a predictable and uniform clinical response. The processing of xenografts subsequently influences physicochemical features, biocompatibility and preclinical performance. Herein, we report a unique proprietary processing method with using a subcritical semi-continuous reactor and subsequent investigation of the resultant HA material.

METHODS: Carefully selected femurs from young bovine were washed with water and extracted in a semi-continuous reactor inside a clean room using controlled high values of pressure and temperature with alkali solution for time periods between 5-8 hours. The HA materials were subsequently washed with a 15% wt.% H₂O₂ solution for 10min and heat treated. The chemical composition was investigated with XRD, FTIR, ICP-MS and physical/surface properties investigated with SEM and BET. Inflammatory & foreign body response i.e biocompatibility was investigated in vivo by sensitization, irritation, cytotoxicity and genotoxicity assays.

RESULTS & DISCUSSION: Chemical investigation confirms no organic impurities including residual proteins, main component being natural carbonate rich hydroxyapatite followed by magnesium (MgO₂) in the periclase or brucite phase. Other elements present in the materials were calcium phosphorus and sodium. Additionally, trace amounts of barium, manganese and iron ions present in quantities similar to natural bone were found. Investigation of physical properties before & after processing reveals minor or no change in physical architecture and preservation of bone-like topography. In vivo biocompatibility reveals no sensitizing, irritating, cytotoxic, genotoxic or pyrogenic reactions as response to materials exposure. Also, no systemic toxicity was detected.

CONCLUSIONS: The rigorous approach to start with clean raw material followed by a unique extraction technology based on high temperature & pressure results in fast extraction of proteins without damage to natural bone surface topography and porosity. Additionally, biocompatibility results of HA are overwhelmingly positive.

INTRODUCTION: Nanowires for use in neural electrodes is a burgeoning field of research that has not been thoroughly characterized in terms of artificial synaptic properties. Nanowires alone are subject to traction forces due to loose connectivity to the electrode. This abstract characterizes various biocompatible substrates for use as an integrating layer for nanowires by way of physical, electrical, and biological measurements.

METHODS: Rat Dorsal Root Ganglion (DRG) explants were extracted and cultured on titanium dioxide (TiO2) or silver (Ag) nanowire networks that had been mixed or layered with various biocompatible coatings (Table 1). Confocal images measured neurite outgrowth. Oxygen-plasma treated coated coverslips were analyzed for impedance and conductance via potentiostat and Electrostatic Force Microscopy. Substrate topology was characterized by SEM. Memristive properties of the substrates was analyzed by an in-lab probe station.

RESULTS & DISCUSSION: DRG explants cultured on nanowire substrates qualitatively exhibited preferential neurite outgrowth in substrates with TiO2 nanowires over Ag nanowires (Figure 1). The sterilization procedure used was found to cause morphological changes to nanowire junctions which could affect electrical behaviour, which is a factor that must be considered when preparing nanomaterial substrates for biological use. Neurite outgrowth results are forthcoming.

CONCLUSIONS: Collectively, these data illustrate the beneficial effect of a coating layer in the promotion of neural culture on nanowire substrates. This project aims to optimize for both biological and electrical applications; further memristive testing will be performed on the optimized substrates.

INTRODUCTION: Parkinson’s disease (PD) is the second most common neurodegenerative disease, affecting more than 10 million people worldwide. The olfactory bulb (OB) is one of the first places affected in PD and it is thought to be involved in the disease pathogenesis [1]-[2]. Herein, we combine OB organotypic slices and DOPAL, a metabolite of dopamine involved in PD progression [3], to create a new platform for testing new therapeutic strategies.

METHODS: OB organotypic slices (300 µm thick) have been obtained from postnatal SD rats (p10) with a McIlwain tissue chopper. The slices have been cultured for 7 days in vitro (DIV) followed by 3 DIV of DOPAL treatment and other 4 DIV of recovery. Slice viability has been assessed using the alamarBlue® assay and the media collected for analysis of nitrite and reactive oxygen species (ROS) at DIV 7, 10, 14. The effects of DOPAL on the bioenergetic performances of OB cells have been studied using the MitoStress Test assay and the Seahorse XFp analyser. Furthermore the OB cell composition have been characterized using immunohistochemistry.

RESULTS & DISCUSSION: OB slices preserve the 3D anatomical structures during culture. DOPAL treatment significantly increases the content of ROS and nitrites (p<0.05), resulting in a reduced viability of treated slices. A possible mechanism of action is through the damage of mitochondria and the impairment of the physiological energy homeostasis in the cells. Signs of mitochondrial damage, like an increased proton leak or a decreased coupling efficacy and spare respiratory capacity, appear minutes after DOPAL is added to the culture media. The bioenergetic health index (BHI) is significantly (p<0.001) reduced upon DOPAL exposure.

CONCLUSIONS: Exposure of cultured olfactory bulb slices to DOPAL causes toxicity that mimics aspects of PD pathology, in particular increased oxidative stress, mitochondrial dysfunction and, lastly, neurodegeneration. This novel experimental platform shows great promise as an innovative, easy and accessible technology for the development of new restorative and regenerative treatments for PD, furthermore raising the enticing possibility of early-stage intervention.

ACKNOWLEDGEMENTS: This project has been funded by the European Union Horizon 2020 Programme (H2020-MSCA-ITN-2015) under the Marie Skłodowska-Curie Innovative Training Networks and Grant Agreement No. 676408.

Cartilage oligomeric matrix protein inhibits angiogenesis in vitro, depending upon its oligomerisation state
E.A. Sastre¹, F. Zaucke², J.W. Bouma¹, K. Maly², G.J.V.M van Osch³, E. Farrell¹

INTRODUCTION: The thrombospondin family is composed of 5 members. TSP-1 and TSP-2 exert potent antiangiogenic functions via their Type 1 repeats, which are absent on the other three thrombospondins [1]. TSP-5 (also known as Cartilage Oligomeric Matrix Protein, COMP) is a homopentameric protein and found predominantly in cartilage and tendon, and during matrix remodeling its oligomeric state is lost [2]. Here we asked if COMP may have an anti-angiogenic role like its other family members TSP-1 and 2, and if that depends on its oligomeric state.

METHODS: The angiogenic effect of COMP on endothelial cells (ECs) was assessed via standard in vitro assays using human umbilical vein endothelial cells (HUVECs). On each assay, media was supplemented with either 10 µg/mL of the recombinant protein (COMP) or with a monomeric COMP derived construct lacking the oligomerisation N-terminal domain (mCOMP). Tube formation assay. ECs were seeded on 96 well plates coated with reduced growth factor basement membrane [Geltrex]. After 24h, tubes were imaged and quantified. Migration assay. ECs were seeded on modified Boyden chambers of 8 µm pore size [Falcon] and allowed to migrate either towards COMP and mCOMP, or from a media containing them towards a chemoattractant media (EGM-2). After 10h, migrated cells were counted.

RESULTS & DISCUSSION: COMP inhibited tube formation of ECs (p<0.01), while at the same concentration mCOMP showed no significant differences (p>0.05). Neither of the forms of the protein induced EC migration (p>0.05). However, when COMP was placed in direct contact with the cells that were allowed to migrate towards a chemoattract medium, a significant reduction of migration was observed (p<0.01), which did not occur with addition of mCOMP (p>0.05).

CONCLUSIONS: COMP plays an antiangiogenic role that depends on its oligomerisation state, which probably involves a different mechanism than that from TSP-1 and -2. This finding supports the idea that an avascular tissue such as cartilage is protected from angiogenesis until its extracellular matrix is degraded.

Novel microfluidic protein patterning method for human-organs-on-chip: Liver-tumor application
E. Ferrari¹, G.S. Ugolini¹, M. Rasponi¹
Presenting Author: Erika Ferrari, erika1.ferrari@polimi.it
¹Department of Electronics, Information and Bioengineering, Politecnico di Milano, Italy

INTRODUCTION: Micropatterned co-cultures (MPCCs) of hepatocytes and 3T3 fibroblasts can maintain higher hepatic functions for several days in vitro, compared to standard culture techniques [1]. Despite the micrometer resolution of protein patterns, so far MPCCs have been used in standard multi-well plates or glass substrates only. Indeed, no methods were described to combine this technology with microfluidic systems. Possible advantages in coupling MPCCs with microfluidic designs include: higher throughput, lower reagent consumption, compatibility with organotypic or multi-organ designs [2]. Here we present a novel technique that allows culture and analysis of MPCCs within a microdevice specifically designed for liver-tumor compartmentalized cultures. The platform is of use in studying drug effects on tumor tissue in the presence of liver metabolism.

METHODS: Microfluidic devices were fabricated following standard photo (SU-8) and soft (PDMS) -lithographies. The liver and tumor chambers were separated by an array of microchannels (5µm high, 3µm wide, 500µm long) to impose a diffusion-based exchange between the compartments. Collagen islands (500µm diameter, 1.2mm center-to-center) were obtained inside microfluidic devices by means of consecutive operations: protein coating, stamp positioning, plasma ablation and bonding of the device. HepG2 cells were seeded at 20·10⁶ cells/mL and allowed to adhere for 20 minutes before a washing step. The following day, 3T3 fibroblasts were seeded at 5·10⁶ cells/mL forming MPCCs. HCT-116 colon cancer cells were seeded at 10·10⁶ cells/mL in the tumor compartment and medium was changed every 24h. Medium supplemented with 100µM Tegafur was added in the liver compartment and the viability of the tumor cells was then evaluated.

RESULTS & DISCUSSION: Microfluidic devices were fabricated and evaluated by dye diffusion to assess the integrity of the microchannels. The patterning and bonding technique resulted efficient with collagen islands of defined circularity successfully obtained inside the liver compartment of the microdevice. MPCCs resulted viable and stable in size. MPCCs were assessed with LIVE/DEAD assay and showed high viability (82%) even after 8 days of culture. Morphologically, HepG2 islands were well maintained during the culture period even though a small loss of circularity was observed after the third day of culture. Ongoing experiments are aimed at validating the platform for pharmacokinetic-based drug screenings. Indeed, Tegafur is a known model drug that increases tumor cytotoxicity after being metabolized by the liver.

CONCLUSIONS: Owing to the fine control of microfluidics, the device described is particularly suitable to study the effect of liver metabolism on anti-tumor drugs. However, our new technology can be applied to potentially all combinations of protein patterns and microfluidic layouts, enabling for new human in vitro studies.

INTRODUCTION: Scaffold architecture, by regulating cell invasion and nutrient transports, is a key parameter for the success of bone tissue engineering. Additive manufacturing techniques allow now to produce scaffolds with controlled architectural features and improved permeability. Such porous scaffolds must, however, be able to sustain high mechanical strain when implanted in load bearing site, even when osteosynthesis material is used. The objective of the study was, therefore, to assess the ability of a cortical reinforcement to improve the mechanical resistance of hydroxyapatite (HA) scaffolds with open and continuous tri-periodic gyroid porosity without impeding bone invasion when implanted in a femoral defect.

METHODS: HA-scaffolds were designed and produced using an innovative process to the anatomic shape of a 3 mm femoral defect in rats, with (i) a macroporous gyroid porosity of 430 µm in diameter (GP) or (ii) with the same gyroid porosity reinforced by a semi-cortical 200 µm thick (GPRC) (total porosity of 60% and 43%, respectively). After manufacturing, morphological characteristics were assessed by micro-computed tomography (CT). Macro- to nano-pores were examined with scanning electron microscopy (SEM). Scaffold mechanical properties were measured with an Instron Universal Testing at constant speed (20 µm/min, n=5/group). Scaffold osteoconductive properties were measured by micro-CT 2, 4, 6 and 8 weeks after implantation in non-critical (3 mm) femoral defects, stabilized with PEEK plates, in female Lewis rats (12-15 weeks of age, n=8/group). 8 weeks after implantation, femurs were explanted and analyzed by high definition micro-CT and histomorphometry for bone formation. Mineralization levels (Ca/P ratio) of newly formed bone were determined by back-scattered electron-SEM (n=5/group).

RESULTS & DISCUSSION: GP and GPRC scaffolds were manufactured with high accuracy in reference to the computerized models. SEM images confirmed that macro- to nano-topography and porosity were similar between both scaffolds. Cortical reinforcement significantly improved scaffold stiffness (GP = 463 ± 68 MPa; GPRC = 664 ± 82 MPa) and resistance to fracture in load bearing site (8/8 GP and 2/8 GPRC scaffolds fractured). Quantity of newly formed bone was similar between both scaffolds, as determined by micro-CT and histomorphometry. Bone, however, was preferentially formed on scaffold borders for the GP and in scaffold center for GPRC scaffolds. Mineralization levels of newly formed bone were also lower for the GPRC than for the GP scaffolds (GP = 1.56 ± 0.07; GPRC = 1.46 ± 0.09).

CONCLUSIONS: For the first time, this study showed that, with a cortical reinforcement, macroporous HA scaffolds can be successfully implanted in load bearing site and that this cortical reinforcement did not impede bone formation within the scaffold.

INTRODUCTION: Dental pulp stem cells (DPSC) are a subset of the mesenchymal stem cell family (MSC) and appreciated for their differentiation capacity, paracrine actions as well as their easy isolation method. As MSC are known to migrate towards tumor lesions (1, 2) and we have shown in vitro migration of DPSC towards a number of different tumor cell lines, we believe that DPSC are suitable carriers to specifically deliver therapy to tumor lesions. Because of the severe side-effects and poor quality of life after current treatments in head and neck cancer patients, there is an urgent need for new personalized and targeted therapies. We hypothesize that DPSC are suitable carriers for gap junction-mediated tumor therapy using the so-called “suicide gene” Herpes Simplex Virus type 1 thymidine kinase (HSV1-tk) in head and neck cancer.

METHODS: Co-cultures of human DPSC and an oral squamous cell carcinoma (OSCC) cell line were set up in different ratios (1:1 to 1:3) to study the formation of gap junctions, through immunocytochemistry against connexin-43 and transmission electron microscopy (TEM). A transwell assay was performed to assess migration of DPSC towards OSCC cells. Interdonor differences in DPSC were assessed regarding gap junction formation and migration. DPSC stably expressing firefly luciferase (Fluc) and HSV1-tk were generated using a lentiviral vector. Transgene functionality was assessed through luminescence assays and cell killing experiments via ganciclovir. A head and neck cancer rat model was optimized using the carcinogen (4-Nitroquinoline 1-oxide) 4NQO dissolved in the drinking water or administered locally. Tumor development was assessed with ex vivo MRI and histology.

RESULTS & DISCUSSION: All DPSC donor lines formed gap junctions with the OSCC cell line in all ratios, confirmed by connexin-43 immunostaining and TEM. We did observe a difference in migration capacity between DPSC donors. Therapeutic DPSC were generated successfully, functionality of Fluc and HSV1-tk was confirmed. Furthermore, a clinically representative rat model for head and neck cancer was optimized using the carcinogen 4NQO, with clear lesions in both models (drinking water vs local administration) as seen with ex vivo MRI and histological stainings.

CONCLUSIONS: These data indicate that DPSC are attractive candidates as vehicles for gap junction-mediated suicide gene therapy. Further in vivo studies will be performed in order to development a novel, targeted and specific therapy for head and neck cancer.

A novel multi-layer functionalized collagen scaffold to regenerate the tendon-to-bone interface
E. Pugliese1,2, D.I. Zeugolis1,2
Presenting Author: Eugenia Pugliese: eugenia.pugliese@nuigalway.ie
1Regenerative, Modular & Developmental Engineering Laboratory (REMODEL), National University of Ireland Galway (NUI Galway), Galway, Ireland 2 Science Foundation Ireland (SFI) Centre for Research in Medical Devices (CÚRAM), National University of Ireland Galway (NUI Galway), Galway, Ireland

INTRODUCTION: The enthesis is a transitional tissue interface between tendon and bone essential for adequate force transmission [1]. Traditionally used monotherapies and tissue substitutes lack to reproduce the complexity of the native enthesis, posing the need for the next generation of multidomain delivery vehicles [2]. We hypothesized that a multi-layer collagen scaffold functionalized with specific growth factors will enhance the functional regeneration of the enthesis.

METHODS: A 3-layer sponge composed by a tendon-like layer of collagen type I, a cartilage-like layer of collagen type II and a bone-like layer of collagen type I and hydroxyapatite was fabricated and cross-linked with poly-ethylene glycol. The cartilage-like layer was functionalized with insulin growth factor 1 (IGF-1) and the tendon-like layer with platelet-derived growth factor (PDGF) and Elisa assay was performed to assess the daily dose released in the media. Histological stainings were performed to assess chondrogenic and osteogenic differentiation of bone-marrow stem cells (BMSCs) seeded on functionalized and non-functionalized scaffolds (Alcian blue and Fast red for proteoglycan production and Alizarin red for calcium deposition, respectively). Tenogenic differentiation of BMSCs was evaluated through expression of specific markers (scleraxis and tenomodulin) by PCR.

RESULTS & DISCUSSION: Elisa assay showed a release of approximately 5 ng/mL in the media up to 21 days. Osteogenic and chondrogenic differentiation of BMSCs cultured in basal media was observed after 21 days specifically localized in the bone-like layer and in the cartilage-like layer, respectively of the non-functionalized scaffold. The IGF-1 functionalized scaffold increased and accelerated proteoglycan production up to day 14 in the cartilage-like layer. Increased expression of tenogenic markers was observed in the PDGF-functionalized scaffold in the tendon-like layer.

CONCLUSIONS: The different collagen composition of the 3-layer sponge together with the growth factor functionalization was able to promote localized differentiation of BMSC into tenogenic, chondrogenic and osteogenic lineage, establishing a promising multi-domain delivery vehicle for the functional regeneration of the enthesis. On-going work is establishing the synergistic effect between different growth factors.

INTRODUCTION: Endometriosis is one of the most common gynecological diseases affecting millions of women worldwide and causing chronic pelvic pain and infertility. It is defined by the presence of endometrial epithelium and stroma outside the uterine cavity. The current gold standard for treatment is purely symptomatic and includes surgical removal of the affected tissue. Endometriosis is considered as a benign disease; however it shares features with cancer, such as neovascularization and metastatic cell behavior [1, 2]. In this study, we aimed to gain insight into the molecular composition of healthy endometrium, endometriosis and endometrial cancer by employing Raman microspectroscopy.

METHODS: Sections of normal endometrium (proliferative phase, n=3), endometriosis (deep infiltrating endometriosis, n=3) and endometrial cancer tissues (n=3) were investigated using Raman microspectroscopy. Raman spectra were collected from epithelial gland cells, their surrounding stromal cells and the associated extracellular matrix (ECM). Molecular profiles of epithelial cells and stroma were compared using multivariate analysis.

RESULTS & DISCUSSION: Raman spectra from epithelial cells in healthy endometrium and endometriosis tissues showed clearly distinct molecular profiles. Notably, glands in endometriosis tissues of different patients were highly heterogeneous in morphology and the obtained Raman spectra. Healthy and cancer tissues showed less patient-variability, indicating potential pathological subtypes in endometriosis. Raman microspectroscopy identified molecular similarities of epithelial gland cells in deep-infiltrating endometriosis with those in endometrial cancer. Moreover, multivariate analysis resolved disease-specific Raman spectral patterns from the ECM surrounding the endometrial glands. These findings indicate a potential role of the microenvironment in the pathogenesis of endometriosis.

CONCLUSIONS: Raman microspectroscopy is a suitable method to differentiate between healthy endometrium and endometriosis. Moreover, it identified similarities of endometriosis and endometrial cancer. This study demonstrates the potential of Raman microspectroscopy as a new tool for the marker-independent identification and characterization of endometriosis.

INTRODUCTION: Foamed calcium phosphate bone cements (fCPCs) constitute a new type of biomaterials. For their preparation as foaming agents usually surfactants are used. To our best knowledge the safe concentration of surfactants in the cement for cells has not been established yet. In this study we have determined non-cytotoxic concentration of three selected surfactants in contact with bone cells.

METHODS: FCPCs used in this study consisted of highly reactive alpha tricalcium phosphate (α-TCP) as the solid phase. α-TCP was obtained by the wet chemical method. The liquid phase for cement pastes preparation was 2 wt% Na₂HPO₄ with addition of 10 wt% of selected non-ionic surfactants: Tween 20 (TW20), Tween 80 (TW80) and Tetronic 90R4 (90R4). The cement without any surfactant served as a control (TCP). Liquid to powder weight ratio was 0.7. The obtained cements were sterilized with ethylene oxide and subjected to MG-63 cell studies. Extracts from the cements were prepared according to ISO 10993 with 1:10 sample to medium ratio. The series of extract dilution were prepared: 1 (undiluted), 2, 4, 8, 16, 32 times. Cells were seeded in 48-well plates at concentration of 1x10⁴ cells/well and after 24 h prepared extracts dilutions were added. Live/dead staining and Alamar Blue assays were done on days 1, 3 and 7.

RESULTS & DISCUSSION: Viability of MG-63 cells by Alamar Blue reduction (%) on day 7 is shown in Fig. 1. Numbers (1, 2, 4, 8, 16, 32) stand for the extract dilution level.

CONCLUSIONS: Our results show that even the extract from TCP material without surfactants diluted by factor 16 resulted in decreased cell viability as compared to cells cultured in pure medium (Ctrl). The mechanism of „false cytotoxicity” of bioactive calcium phosphate ceramics of high surface area has been already explained [1]. TW20 was the most cytotoxic. Eight times diluted extracts from cements with the individual surfactant addition resulted in the same cell viability as compared to Ctrl. Taking this into account we can establish that 1.25 wt% addition of studied surfactants in liquid phase of a cement is a safe concentration for cells. Surfactants in such concentration in liquid phase provide sufficient foaming ability for preparation of fCPCs.

Fluid flow supported angiogenic sprouting into granular hydrogels
F. Stein¹, V.D. Trikalitis¹, J. Rouwkema¹
Presenting Author: Fabian Stein, f.stein@utwente.nl
¹Department of Biomechanical Engineering, Technical Medical Centre, University of Twente, 7522NB Enschede, The Netherlands

INTRODUCTION: The unique physical properties of granular hydrogels making them an increasingly promising tool for the field of tissue engineering [1]. Depending on the hydrogel material used, it has been shown that granular hydrogels support cell survival, cell growth, and network formation of single cells and multicellular spheroids [2,3]. Herein, we analyzed the first time the effect of fluid flow in combination of the angiogenic growth factor VEGF₁₆₅ in granular hydrogels on vascular sprouting in a microfluidic system.

METHODS: A five-channel microfluidic platform was designed and fabricated, with a channel height of 100 µm. Human umbilical vein endothelial cells (HUVECs) were seeded in one of the two outer fluid flow channels at 6*10⁶ cells/mL to obtain a confluent monolayer. Collagen type I from rat tail (Sigma Aldrich) at a concentration of 6 mg/mL was used to create a barrier to entrap the granular hydrogel suspension made of agarose-collagen in the middle channel. The remaining second outer channel was used as a source of VEGF₁₆₅ in a concentration of 50 ng/mL to stimulate angiogenesis and proliferation. Cells were pre-labelled with the cell tracker CMFDA (Thermo Fisher Scientific) to allow for imaging of the formation of vascular sprouts into the granular hydrogels over a period of 7 days using confocal microscopy. Images were subsequently analysed using ImageJ. To characterize the diffusion of growth factors added into the microfluidic device through the solidified hydrogel and hydrogel suspension, diffusion experiment were performed using FITC-conjugated dextran.

RESULTS & DISCUSSION: The results obtained showed that the granular hydrogels could indeed be isolated and stabilized in the central microfluidic channel by the incorporation of a collagen hydrogel barrier. Furthermore, by instituting a pressure difference over the two side channels, a fluid flow over the hydrogel compartment could be instituted. By addition of soluble exogenous angiogenic growth factor VEGF₁₆₅ an increased vessel growth into the granular hydrogels could be observed. The extent of vessel growth could further be controlled by varying the composition of the hydrogel suspension.

CONCLUSIONS: One of the main limitations in tissue engineering is the lack of a sufficient blood vessel system. By showing that granular hydrogels can facilitate the formation of a capillary bed in combination with fluid flow and gradients of growth factors, we have developed a promising platform to further investigate the creation of larger vascularized tissue constructs based on granular hydrogels.

INTRODUCTION: Over the last years, the transcriptional co-factor Yes-associated protein (Yap) has gained increasing interest as a potential therapeutic target for the treatment of osteoarthritis, a very common and debilitating joint disease that affects 9 million people in the UK only [1][2]. Here, anti Yap gapmers (5 kDa), single stranded RNAi oligos able to be self-internalized by cells, were designed and encapsulated for controlled release. The delivery of small compounds (<1 MDa) within the joint cavity is strongly impaired by their rapid clearance (1-24 hours), in contrast to bigger ones (>200 nM) with longer joint-residence times (2-35 days) [3]. Therefore, to increase retention and obtain sustained delivery of gapmers, we developed CaCO3 microparticles for gapmer encapsulation and release.

METHODS: A co-precipitation method was used to encapsulate 60 µg of gapmers into 0.65 mg of CaCO3 microparticles. Microparticles size was determined by transmission electron microscopy. Encapsulation and release were quantified by spectrophotometry. To test silencing efficiency, the media of primary synovial MSCs was replaced daily and incubated with the released gapmers from CaCO3 microparticles.

RESULTS & DISCUSSION: After gapmer/CaCO3 microparticles formation, a size of 3.03±0.38 µm (mean ± SD, n=3) and an encapsulation efficiency of 96.4%±1 (mean ± SD, n=3) were obtained. Release studies highlighted an initial burst release of 41.3% of the cargo within the first 24 hours and a continuous release of an additional 18.8% over 7 days. Silencing studies led to reduced Yap mRNA expression of 61%±9 and 36%±22 (mean ± SD, n=3) after 2 and 4 days, respectively.

CONCLUSIONS: Collectively, this work introduces a novel gapmer deliver strategy with favorable size properties for joint retention and sustained release.

INTRODUCTION
There is increasing clear that mechanical loading plays a key role in regulating the differentiation of mesenchymal stem cells (MSCs) into matrix producing chondrocytes \cite{1, 2}. The aim of this study was to optimize the properties of fibrin hydrogels for tissue engineering (TE) and mechanobiology studies. Subsequently, the response of MSCs embedded in soft and stiff fibrin hydrogels to dynamic compression (DC) was investigated in the absence of any specific chondrogenic growth factor.

METHODS: MSCs were encapsulated in soft and stiff fibrin hydrogels (fibrinogen: 50 mg/ml in aprotinin-NaCl\textsubscript{2} solution; thrombin: 2.5 U/ml in DMEM with 1 mM CaCl\textsubscript{2} (soft) or 20 mM CaCl\textsubscript{2} (stiff) using silicon moulds and polymerized at 37 °C for 40 min. The elastic modulus of the fibrin hydrogels was determined using an unconfined compression test. The obtained cylindrical hydrogel constructs were subjected to DC for 2 weeks (2h/day; 5days/week; 1 Hz; 10% strain; 37 °C; 5% O\textsubscript{2}; 5% CO\textsubscript{2}) and the expression of chondrogenic marker genes SOX9 and aggrecan (ACAN) was examined.

RESULTS & DISCUSSION: hMSCs were encapsulated in soft ($\approx$21.9 kPa) and stiff ($\approx$30.6 kPa) hydrogels and loaded for two weeks in the absence of specific chondrogenic growth factors. RT-qPCR indicated an increase in SOX9 after one ($p=0.015$) and two weeks ($p=0.0052$) in DC samples in stiffer gels. DC had no significant effect on the expression of chondrogenic genes within the softer hydrogels. In fact, DC was found to reduce the expression of ACAN in soft fibrin hydrogels.

CONCLUSIONS: The significant increase of the chondrogenic transcription factor SOX9 in stiffer gels upon the application of DC indicates the importance of hydrogel properties in determining the cellular response to such extrinsic mechanical cues. Hence it is crucial to consider stem cell mechanobiology when designing hydrogels for cartilage TE.

INTRODUCTION: Platelet-Rich Plasma (PRP) is a concentrated form of platelets in plasma. Growth factors (GF) with rich content of chemokine and cytokines can stimulate cell chemotaxis, proliferation, differentiation, angiogenesis and production of extracellular matrix. Thanks to these properties, it is used to support tissue regeneration in many different clinical areas [1-3]. Nowadays, PRP used for this purpose is prepared just as autolog and produced before application. Therefore, quality, content and effectiveness of product vary by the manufacturer, the current blood values of the donor or the method used. The aim of this study is to investigate the most suitable method for universal PRP product which is ready to use, standard, sterile, safe, and concentrated.

METHODS: Three different male volunteers at the ages of 21, 27 and 28 were treated with thrombocyte apheresis. After the obtained platelet suspension (PRP) was irradiated, some parts were directly frozen and some were stored at -20° C after lyophilization. With cell samples, pH, osmolarity, Eliza, GF content measurements (EGF, VEGF, PDGF) and efficacy analysis (MSC Proliferation Assay) were performed from fresh samples and samples thawed at 1st, 3rd and 12th months after storage. The assessments were done with the average of the independent 3 donors.

RESULTS & DISCUSSION: Compared to fresh PRP, no negative effect of irradiation has been detected on cell number, osmolarity, pH and GF release. The number of cells in the lyophilized group decreased significantly (p<0,05). The groups stored in lyophilized form were found to retain the GF concentration better than the freeze-conserved groups. In the 12th month, no change in the pH measurements was observed (p>0,05), but the osmolarity was lower (p<0,05). In the MSC proliferation test compared to fresh PRP, it was observed that in the lyophilized group there was found no significant difference (p>0,05).

CONCLUSIONS: The data obtained shows that PRP collected by platelet apheresis preserve its efficiency for 3 months after irradiation and lyophilization and with this way it can be used as a ready for use, safe, effective and universal product. The low osmolarity values measured due to cell loss in the lyophilized PRP groups will reach fresh PRP value by optimizing cell concentration with taking into account the amount of loss. The study will be developed at an advanced level by increasing the number of samples, adding different GF/cytokine assays, and supported by diagnostic-based in vivo studies.

INTRODUCTION: Stem cell therapy has a great promise for the treatment of various
diseases. Placenta derived stem cells have desirable and unique characteristics that make them
highlighted among the other stem cells and attractive for cell therapy [1]. The aim of this research
was to evaluate the effect of BMP and its antagonist, noggin, on neural and keratinocyte
differentiation.

METHODS: The amnion layer was mechanically peeled off from the chorion and human amniotic
epithelial cells were isolated with trypsin-EDTA in 37°C. Then, cells were exposed by
differentiation medium include BMP-4 (25 and 50 ng/ml), noggin (50 and 100 ng/ml), heparin
(1ul/ml). After 21 days, cells were fixed and characteristic analysis of AEC-derived ectodermal
(neurons and keratinocytes) was performed by flow cytometry. The following primary antibodies
were applied for flow cytometry: Map2 (neuron marker), Olig2 (oligodendrocyte marker), K14
(keratinocyte marker).

RESULTS & DISCUSSION: These results showed that percent of MAP2 expression was 74.07±
1.8 for 50 ng noggin, Olig2 expression 60.8 ± % 0.7 for 25ng/ml BMP-4 and k14 expression 64.45%
± 0.5 for heparin group compared with control group.

CONCLUSIONS: The results of this study illustrated the AECs have capability to differentiate into
neuronal, glial and keratinocyte cells by noggin, BMP4 and Heparin, respectively

INTRODUCTION: The AUTOSTEM platform is a pipeline to fully automate all steps necessary
for producing stem cells on a multi litre scale, including cell expansion, formulation, and
cryopreservation.

MOTIVATION: Mesenchymal stem cells (MSC) are a promising therapeutic agent in the field of
regenerative medicine. They can be isolated from a variety of tissues and are in advanced clinical
testing for a number of clinical indications. The manual production of MSCs currently depends
largely on manual labour and is furthermore highly sensitive to production variations and errors. In
order to increase the capacity for production and the reproducibility, the robotic platform
AUTOSTEM has been developed.

METHODS: The biological process of cultivating MSCs covers extracting the cells from bone
marrow, growing them in a bioreactor, performing frequent cell counts, and finally transferring the
cells into cryo-tubes for freezing. In the AUTOSTEM platform, all processes after cell extraction are
executed automatically while being GMP-ready. Therefore, medical and biological devices, like
bioreactors, a cell counter, and a centrifuge, have been linked to a central control system responsible
for an adaptive process control. Furthermore, devices like a pumping station, a sampling station,
decappers, and an automated pipette have been developed especially for AUTOSTEM. Two robots
transport cells and material from one station to another. In order to provide a safe environment for
the different production steps, the platform consists of different biosafety levels. Cells can be
transferred from grade A to D through a hatch and from grade D to A trough an innovative fluid
transferring device.

RESULTS & DISCUSSION: The automated handling functions for cells and materials as well as
the sterility of the bioreactor have been successfully tested. Furthermore, it has been shown that the
bioreactors can produce cells. The characterisation of the cell products was undertaken and assay
results showed the quality of the MSC product to be comparable to cells grown on microcarriers in
spinner units or those grown in traditional T flasks in terms of surface marker expression and
differentiation potential.

CONCLUSIONS: Further optimizations are planned for AUTOSTEM. Next steps to clinical
application are the demonstration of full GMP compliance as well as further improvements of several
modules. There is potential to adapt the AUTOSTEM platform for the automated production of other
cell types.

INTRODUCTION: Hyaluronic acid (HA) is a polysaccharide found in the extra cellular matrix (ECM) of various tissues in the body [1]. One of the most important biological roles of HA is linked to its immunomodulatory properties, which depend on HA molecular size [2]. For this reason, HA is a material of increasing significance to biomaterials science and it is finding applications in a wide range of areas, including drug delivery and regenerative medicine. However, since HA is readily degraded in physiological conditions due to hydrolysis and enzymatic degradation, chemical modification is necessary in order to increase HA structural stability. In this project, HA was successfully crosslinked using a new biocompatible di-isocyanate crosslinker. In order to verify the biocompatibility and the immune response triggered by these novel gels, L929 fibroblast cell line originated from mice are used as a first line of testing.

METHODS: A range of samples was produced utilizing HA with 0.1 MDa (low molecular weight - LMW) and with 1.2 MDa (high molecular weight - HMW). Heterogeneously crosslinked HA films (7% wt/v) using 200 mg/mL of crosslinker were selected for proliferation and immune response tests (Figure 1). Proliferation was assessed using Alamar Blue metabolic activity assay. L929 fibroblasts secrete macrophage colony-stimulating factor (GM-CSF), a cytokine that initiate macrophage differentiation as part of the immune response chain. Upon culturing L929 cells on our novel HA gels, GM-CSF is measured at different time intervals by taking aliquots of media using an ELISA kit.

CONCLUSIONS: LMW HA gels show decreased proliferation rates than HMW gels, which correlates with immune activation and GM-CSF cytokine production. Thus, it is envisaged that LMW HA gels (0.1 MDa) due to its pro-inflammatory characteristics can be exploited for the delivery of vaccines, in order to further instigate the immunisation and recruitment of immune cells. Moreover, the HMW HA gels (1.2 MDa) can be used for cell encapsulation in order to decrease the immune rejection of transplanted cells.

Figure 1: Bright field images of 1.2 MDa gels at 4 hours (a) and 48 hours (b) after L929 cell seeding.

INTRODUCTION: 3D bioprinting is a technology that allows the creation of stable-high-defined structures containing cells mimicking the biological environments [1]. Its applications range from ex vivo models for drug design and cancer studies to the development of organoids and clinical translation. Proper bioinks must be capable of maintaining the depicted structure without losing fidelity offering simultaneously an adhesive and biomimetic extracellular matrix (ECM). Herein a novel photo-crosslinkable mono-component Elastin-Like Recombinamer (ELR) bioink was developed. Concentration and temperature printing conditions were optimized as well. ELRs were characterized in terms of viscosity, dynamics modulus and intern cross-sections. Citocompatibility was evaluated by proliferation and viability studies in presence of fibroblasts.

METHODS: Genetically engineering Elastin-Like Recombinamer (ELR) bearing a silk domain (((VPGKG)48-(IPGVG)60-(GAGAGS)52-RGD6) was biosynthesize in Escherichia Coli bacteria. The purified recombinamer was modified with methacrylamide (MA) by an amidation reaction using the ε-amino groups present in the lysine aas. ELR-MA was dissolved in PBS at different concentrations conducting printing tests at temperatures over and below transition temperature, exposing UV during printing with an extrudable printer. Deposition of several layers was studied. Bioink viscosity and dynamic modulus of photo-crosslinked structures at selected concentration was measure. Internal porous cross-sections were characterized by SEM. Proliferation and viability of printed patterns loaded with fibroblasts were studied by Life/Dead and Alamar blue assays.

RESULTS & DISCUSSION: ELR-MA at best temperature (14ºC) and concentration (190mg/mL) conditions exhibited great printability (~1) in small mesh constructs (1.5mm pore size). Bioink viscosity at selected concentration was high (10Pa·s), showing a non-Newtonian liquid behavior decreasing viscosity with %shear rate allowing better extrudability. Dynamic modulus of photo-crosslinked structures displayed hydrogel characteristic G’>>G”. SEM analysis showed an intern porosity of (~8um). RGD bioactive sequences included in hydrogel ensured fibroblasts adhesion, viability and proliferation studied by Life/Dead and Alamar blue assays.

CONCLUSIONS: These results show the potential of an ELR-MA photo-crosslinkable hydrogel for the 3D bioprinting of structures in the field of tissue-engineering applications.

INTRODUCTION: Smart materials have gained widespread interest in the material science, they have been used in a large variety of applications [1]. Elastin-like Recombinamers (ELRs) show extraordinary properties in numerous biomedical fields [2]. Moreover it has been demonstrated that the Inverse Temperature transition (Tt) which, is a typical feature of ELRs, can be modulated by the addiction and/or the removal of chemical groups such as phosphate groups [3].

METHODS: Recombinant DNA techniques were used for the synthesis of smart-ELRs containing kinase consensus sequences and RNAse A sequence. A set of smart-ELRs were designed, expressed and bioproduced in E. coli. The ELRs were composed by the inclusion of 10 consensus sequence phosphorylation sites regularly distributed along the (VPGIG)n chain. The phosphorylation was performed by cAMP - dependent protein kinase (PKA) catalytic subunit, whereas de-phosphorylation was performed by alkaline phosphatase Calf Intestinal (CIP). In order to verify the effectiveness of the phosphorylation and to quantify the number of phosphate groups transferred and removed from and to the smart-ELRs, the samples were analyzed by HR-Massa and the Tt was characterized by turbidity analysis. Finally, the RNAse catalytic activity was monitored following a RNAse quantification method [4].
