Estimation effects on stop-loss premiums under dependence

Willem Albers and Wilbert C.M. Kallenberg
Department of Applied Mathematics, University of Twente, The Netherlands

Abstract Even a small amount of dependence in large insurance portfolios can lead to huge errors in relevant risk measures, such as stop-loss premiums. This has been shown in a model where the majority consists of ordinary claims and a small fraction of special claims. The special claims are dependent in the sense that a whole group is exposed to damage. In this model, the parameters have to be estimated. The effect of the estimation step is studied here. The estimation error is dominated by the part of the parameters related to the special claims, because by their nature we do not have many observations of them. Although the estimation error in this way is restricted to a few parameters, it turns out that it may be quite substantial. Upper and lower confidence bounds are given for the stop-loss premium, thus protecting against the estimation effect.

Keyword and phrases: Dependent claims; stop-loss premium; aggregate claims; estimation error; confidence bounds.

2000 Mathematics Subject Classification: 62E17, 62P05, 62F10

1 Introduction

A well-known risk measure for large insurance portfolios is the so called stop-loss premium \( E(S - a)^+ = E\{\max(0, X - a)\} \), where \( S \) denotes the sum of the individual claims during a given reference period and \( a \) is called the retention. The classical model takes \( S \) as a sum of independent terms. This is often not realistic. On the other side of the spectrum, the assumption of comonotonicity produces astronomical effects due to its strong form of dependence. In practice, the dependence will be at a much lower level. However, it has been shown in Albers (1999), Reijnjen et al. (2005) and Albers et al. (2006) that even small dependencies can lead to huge errors in relevant risk measures, such as stop-loss premiums. Attributing on average a fraction of merely 1%-5% of the total claim amount to a common risk part turns out to already allow increases of stop-loss premiums by 200%-600%, when dealing with normally distributed claim size distributions, or even up to 50000% for more realistic skewed claim size distributions; see Albers (1999) and Reijnjen et al. (2005). Therefore, this small fraction of dependence should certainly not be ignored. On the other hand, complete comonotonicity seems to be too much. In fact, on the scale independent-comonotone the model with a (small) common risk part is still close to the independent end-point. For a more detailed discussion on this topic we refer to Reijnjen et al. (2005), pp.247-249.

The previous results were obtained in a rather simple model. A more general and flexible model has been presented in Albers et al. (2006). The model makes a distinction between

"ordinary" claims, where independence may be assumed, and a small fraction of "special" claims, where dependence appears in the form that a whole group is exposed to damage, due to a special cause (such as an epidemic, an accident, a hurricane etc.). The model is general in the sense that it allows groups of varying sizes, which moreover may overlap and on the other hand do not have to span the whole portfolio. It is flexible, in the sense that it does not require information which is and will remain unavailable from the data. For example, it sometimes may not be easy to identify those individuals who are exposed to a special cause, but did not file a claim. In fact, the model only needs the realized number of special claims.

As usual in stochastic models parameters appear which have to be estimated. Replacing the unknown model parameters by their estimated counterparts obtained from the data, will result in estimation errors. Just as with ignoring the dependence effect, it is too optimistic to act as if the estimation errors are negligible, unless we have a large number of observations. This topic, the effect of the estimation step, is exactly the issue which is addressed in the present paper.

In Section 2 the model is introduced. It turns out that the model is too complicated to allow an exact evaluation of the estimation effects in such a way that transparent conclusions can be drawn. Therefore, we use some approximations. The accuracy of these approximations have been settled in Lukocius (2007). Two aspects play a role when considering the effect of the estimation step. Obviously, in the first place the accuracy of the estimators, but secondly, also the fluctuation of the stop-loss premium as function of the parameters. The set of parameters may be divided into two parts, those concerning the ordinary claims and those who are inserted in particular for the special causes. For the first part we have a lot of data and these parameters can be estimated very accurately. Due to their nature, special causes do not appear very often and hence estimation of the parameters linked up with the common risk part is much less accurate. As remarked before, their influence on the final outcome, even when a rather small part is due to a common risk, is quite large and hence estimation of the parameters connected with the special causes is the most important issue.

In Section 3 the needed structure of the observations to obtain estimators is given and the estimators based on them are derived. The fluctuations of the stop-loss premium are discussed in Section 4. The behavior of the estimators is the subject of Section 5. Asymptotic normality of the estimators, with respect to the expected total number of claims tending to infinity, is derived. The results of Sections 4 and 5 clearly show that the estimation effect is dominated by the part of the parameters related to the special causes. This is one of the main conclusions of the paper, implying that we only have to worry about that part of the estimation procedure, which simplifies matters. At the same time it is shown that the influence of these remaining estimators in general will be substantial. Hence, the estimation step cannot be ignored. That is the second main conclusion of the paper. In Section 6 it is shown how we can protect against the estimation error. Confidence bounds are derived for that purpose.

The paper is written in such a way that it can be extended in an easy way to other risk measures as for instance the value at risk, since in the theory no special properties of the stop-loss premium are used. Therefore, this part of the paper can be easily generalized with appropriate modifications when other risk measures are applied. Obviously, this does not hold for the numerical calculations, as presented in the tables and figures, where the particular form of the (accurate approximation of the) stop-loss premium, given in the Appendix, is explicitly used.

2 The model

The model is a so called collective model and consists of two parts, the ordinary claims and the special claims, where whole groups are involved. Examples are man and wife both insured in the same portfolio, carpoolers using a collective company insurance, catastrophes like hurricanes or floods hitting numerous insured at the same time. For more details we refer to Albers et
al. (2006), where the relation with the individual model is given and the impact of the model parameters is discussed. Here we restrict attention to a brief description of the model.

We use the following notations

\[ N : \text{number of the ordinary claims}, \]
\[ C_i : i^{th} \text{ claim size of the ordinary claims}, \]
\[ H : \text{number of groups}, \]
\[ G_k : k^{th} \text{ group size}, \]
\[ D_{jk} : j^{th} \text{ claim size in } k^{th} \text{ group}. \]

We assume that \( C_1, C_2, \ldots, N, H, G_1, G_2, \ldots, D_{11}, D_{12}, \ldots \) are independent random variables. All the \( C_i \) and \( D_{jk} \) have the same distribution and also the \( G_k \) have a common distribution. The total sum of claims is given by

\[ S = \sum_{i=1}^{N} C_i + \sum_{k=1}^{H} \sum_{j=1}^{G_k} D_{jk}. \]

Here we clearly see the two parts. The first sum concerns the ordinary claims, the second sum refers to the special claims. They occur groupwise, thus representing dependence in the total claim size. The occurrence of a special claim does not result in a single claim, but in a lot of claims together. So, in this part comonotonicity appears: the whole group has damage.

The supposed distributions of the random variables are as follows. Here \( P \) denotes the Poisson distribution and \( \mu_G = EG \).

\[ C_i, D_{jk} : \text{Gamma, inverse Gaussian or lognormal} \]
\[ N : P(\lambda(1-\varepsilon)) \]
\[ H : P \left( \frac{\varepsilon \lambda}{\mu_G} \right) \]
\[ G_k : P(L) \text{ with } L : \text{Gamma or inverse Gaussian}. \]

The idea is that a fraction \( \varepsilon \) of \( \lambda \), the total expected number of claims, is due to special causes. As \( \varepsilon \) typically will be (very) small, this clearly shows that the dependence part is really small in terms of the fraction of total expected number of claims. Nevertheless, this may lead to a huge total claim amount, with major consequences for the stop-loss premiums. Since special claims do not occur that often, a pretty high aggregation level is needed. The assumption, therefore, that all special claims lead to similar group sizes, seems rather awkward. Hence \( G_k \), the number of realized claims in the \( k^{th} \) group, follows an overdispersed Poisson distribution.

To obtain independence of \( H, G_1, G_2, \ldots \), the following assumptions are sufficient: take \( H, L_1, L_2, \ldots \) independent, let \( G_1|H = h, L_1 = l_1, L_2 = l_2, \ldots, G_2|H = h, L_1 = l_1, L_2 = l_2, \ldots \) be independent and assume that the distribution of \( G_k|H = h, L_1 = l_1, L_2 = l_2, \ldots \) depends only on \( l_k \). Then it is easily seen that \( P(H = h, G_1 = g_1, \ldots, G_h = g_h) = P(H = h)P(G_1 = g_1)\ldots P(G_h = g_h) \). So, essentially, we first select an \( L_i \), and given its outcome \( l_i \) we subsequently let \( G_i \) follow a Poisson distribution with parameter \( l_i \), thus allowing more variation in the group size than in case of a Poisson distribution with a fixed parameter.

Let the standard deviation of a random variable be denoted by \( \sigma \) and let \( \gamma = \sigma/\mu \) be its coefficient of variation. The range of parameters that is of interest is given by

\[ \lambda \geq 400, \varepsilon \leq 0.05, 5 \leq \mu_G = \mu_L \leq 20, 0.5 \leq \gamma_G \leq 2.5 \quad (2.1) \]
\[ \gamma_L \leq 1.5 \text{ for } L : \text{Gamma, } \gamma_L \leq 2.5 \text{ for } L : \text{inverse Gaussian.} \]

For instance, when \( \lambda = 100 \) and \( \varepsilon = 0.02 \), the expected number of special claims is merely 2. If we take \( \mu_G = 10 \), the expected number of such groups would only be 0.2. This really seems
to be too small. For more detailed information about the choice of the range of parameters we refer to Albers et al. (2006), Section 5.

**Remark 2.1** The group size $G$ has expectation $\mu_G$, which in the range of parameters of interest varies between 5 and 20. Hence, $G$ will as a rule be at least equal to 2. However, a value of $G$ equal to 1 is possible. In that case we do not really have a group and it will not be recognized as such. Therefore, one might argue that we should restrict attention to distributions of $G$ starting with 2. For most of the theory developed here this will cause no problem: the results continue to hold for general $G$. In view of that we will often give the results for this general setting, using the parametrization $\mu_G, \gamma_G$ instead of $\mu_L, \gamma_L$ (see also Remark 3.1). By definition of $G$ the relation between the two forms of parametrization is simply given by

$$
\mu_G = E(E(G|L)) = \mu_L,
$$

$$
\gamma^2_G = \text{var} \left( \frac{G}{\mu_L} \right) = \mu_L^2 \{ \text{var}(E(G|L)) + E(\text{var}(G|L)) \} = \mu_L^{-2} \{ \text{var}(L) + EL \} = \gamma^2_L + \mu_L^{-1}.
$$

On the other hand, in practice we do not have to worry about the restriction, because a value of $G$ equal to 1 will occur only rarely and we may ignore it without making large mistakes. □

## 3 Observations and estimators

The basic data are for each individual the pairs $(X_i, Y_i)$ with $X_i$ the claim amount and $Y_i$ the group code, 0 for the independent (ordinary) claim and 1, 2, ... for the various dependent claims (due to a common risk). From the observed basic data $(x_i, y_i)$ we can deduce

- $n$: the number of independent claims
- $c_1, ..., c_n$: the claim amounts for the independent claims
- $h$: the number of group codes for the dependent claims
- $g_1, ..., g_h$: the group sizes
- $d_{11}, ..., d_{gh}$: the claim amounts for the dependent claims.

It will typically not be enough to have these data for one year, we usually will need data from several years $t = 1, ..., u$, say. The reason for that is the scarcity of special claims. To get reasonable estimates of $\varepsilon, \mu_G$ and $\gamma_G$ we need data from an extended period. The estimators will be based on $N_t, C_{1t}, ..., C_{N_{1t}}, H_t, G_{1t}, ..., G_{H_t}, D_{11t}, ..., D_{G_{H_t}H_t}$, for $t = 1, ..., u$.

For the observed data $n_t, c_{1t}, ..., c_{nt}, h_t, g_{1t}, ..., g_{ht}, d_{11t}, ..., d_{g_ht}$, with $t = 1, ..., u$, the likelihood equals

$$
\prod_{t=1}^{u} \left[ \frac{\exp(-\lambda(1-\varepsilon))^{nt}}{nt!} \left( \prod_{i=1}^{nt} f_C(c_{it}) \right) \frac{\exp(-\varepsilon\lambda\mu_G^{-1})(\varepsilon\lambda\mu_G^{-1})^{ht}}{ht!} \left( \prod_{k=1}^{ht} P(G = g_{kt}) \right) \left( \prod_{j=1}^{g_{kt}} f_C(d_{jkt}) \right) \right] \times \frac{1}{n_t!h_t!u^{nt+ht}}
$$

$$
= \exp(-\theta)\theta^{nt} + h_{tot} p^{htot} (1 - p)^{ntot} \times \prod_{t=1}^{u} \prod_{k=1}^{ht} P(G = g_{kt}) \left( \prod_{i=1}^{nt} f_C(c_{it}) \right) \left( \prod_{k=1}^{ht} \prod_{j=1}^{g_{kt}} f_C(d_{jkt}) \right) \times \frac{1}{n_t!h_t!u^{nt+ht}}
$$
with
\[ \theta = \theta(\lambda, \varepsilon, \mu_G) = u\lambda(1 - \varepsilon + \varepsilon\mu_G^{-1}), \]
\[ p = p(\varepsilon, \mu_G) = \frac{\varepsilon\mu_G^{-1}}{1 - \varepsilon + \varepsilon\mu_G^{-1}}, \]
\[ n_{tot} = \sum_{t=1}^{u} n_t \quad \text{and} \quad h_{tot} = \sum_{t=1}^{u} h_t. \]
For short we will often write \( n \) and \( h \) instead of \( n_{tot} \) and \( h_{tot} \). Maximizing the likelihood w.r.t. \( \lambda \) for given \( \varepsilon, \mu_G \) gives \( \hat{\lambda} = n + h \) and hence
\[ \hat{\lambda} = \hat{\lambda}(\varepsilon, \mu_G) = \frac{n + h}{u(1 - \varepsilon + \varepsilon\mu_G^{-1})}. \] (3.1)
Inserting it and noting that \( \exp(-\hat{\lambda})\hat{\lambda}^{n+h} \) does not depend on \( (\varepsilon, \mu_G) \), the likelihood is maximized w.r.t. \( \varepsilon \) for given \( \mu_G \) by taking \( \hat{p} = h/(n + h) \) and hence
\[ \hat{\varepsilon} = \hat{\varepsilon}(\mu_G) = \frac{h}{h + n\mu_G^{-1}}. \] (3.2)
Inserting this and noting that \( \hat{p}^h(1-\hat{p})^n \) does not depend on \( \mu_G \), it is seen that we end up with the likelihood of the \( G \)'s times the likelihood of the \( C \)'s and \( D \)'s. This means that we can proceed with estimating the parameters of the distribution of \( G \) using only the \( G \)-observations and, separately, estimating the parameters of the distribution of \( C \) using the \( C \)- and \( D \)-observations.

Taking for \( L \) the Gamma-distribution, it follows that \( G \) has a negative binomial distribution. Although in general the number of observations from this negative binomial distribution, \( \sum_{t=1}^{u} H_t \), will be not very large, the expectation of \( G \) is as a rule not small, say between 5 and 20. Under these circumstances, Saha and Paul (2005) show that moment estimators are a good alternative to maximum likelihood estimators.

Both when \( L \) has a Gamma distribution and when \( L \) has an inverse Gaussian distribution, \( G \) has a distribution with two parameters. Moment estimators do not depend on the parameterization. It is convenient to take as parametrization for \( G \) its expectation \( \mu_G \) and its coefficient of variation \( \gamma_G \) (see also Remarks 2.1 and 3.1). The moment estimates of the expectation and coefficient of variation are
\[ \hat{\mu}_G = \frac{\gamma}{h} = \frac{1}{h} \sum_{t=1}^{u} \sum_{k=1}^{h_t} g_{kt}, \]
\[ \hat{\gamma}_G = \sqrt{\frac{g_f^2 - \overline{g}^2}{\overline{g}^2}} \quad \text{with} \quad \overline{g}^2 = \frac{1}{h} \sum_{t=1}^{u} \sum_{k=1}^{h_t} g_{kt}^2. \]
Inserting \( \hat{\mu}_G \) in \( \hat{\varepsilon} \), see (3.2), and writing \( g_{tot} = \sum_{t=1}^{u} \sum_{k=1}^{h_t} g_{kt} \), yields
\[ \hat{\varepsilon} = \frac{h}{h + n\overline{g}^{-1}} = \frac{\frac{h\gamma}{\overline{g}^2 + n}}{\frac{h\gamma + n}{\gamma_G + n}} = \frac{g_{tot}}{g_{tot} + n_{tot}}, \] (3.3)
which as the observed fraction special claims indeed is the "natural" estimate of \( \varepsilon \). Inserting \( \hat{\varepsilon} = h\overline{g}/(h\overline{g} + n) \), \( \hat{\mu}_G = \gamma \) in \( \hat{\lambda} \), see (3.1), moreover gives
\[ \hat{\lambda} = \frac{h\overline{g} + n}{u} = \frac{g_{tot} + n_{tot}}{u}, \]
which as the observed total number of claims divided by the number of years also is the "natural" estimate of \( \lambda \). Writing
\[ \overline{h} = \sum_{t=1}^{u} \frac{h_t}{u} = \frac{h}{u} \overline{n} = \frac{\sum_{t=1}^{u} n_t}{u} = \frac{n}{u}, \]
we may also write

\[ \hat{\lambda} = h \hat{\eta} + \pi. \]

For the estimation of the two parameters of the distribution of \( C \) we have many observations at our disposal. Hence here we clearly can use moment estimators as well. As parametrization we once more take the expectation \( \mu_C \) and the coefficient of variation \( \gamma_C \). This leads to

\[ \hat{\mu}_C = \frac{c + d}{n_{tot} + y_{tot}}. \]

\[ \hat{\gamma}_C = \frac{\sqrt{c^2 + d^2} - c + d}{c + d} \]

with \( c^2 + d^2 = \frac{\sum_{t=1}^{u} \sum_{i=1}^{n_t} c_{it}^2 + \sum_{t=1}^{u} \sum_{j=1}^{h_t} d_{jk}^2}{n_{tot} + y_{tot}}. \)

Summarizing: our estimators are

\[ \hat{\mu}_C = \hat{\mu}, \quad \hat{\gamma}_C = \frac{\sqrt{G^2 - \hat{\mu}_C^2}}{\hat{\mu}}, \]

\[ \hat{\gamma}_C = \frac{G_{tot}}{G_{tot} + N_{tot}}. \]

Remark 3.1 Obviously, we can replace the parameters \( \mu_G, \gamma_G \) and its estimators \( \hat{\mu}_G, \hat{\gamma}_G \) by the parameters \( \mu_L, \gamma_L \) and the corresponding estimators \( \hat{\mu}_L, \hat{\gamma}_L \). Because \( \mu_G = \mu_L \) and \( \sigma_G^2 = \sigma_L^2 + \mu_L^2 \), implying that \( \gamma_L = \mu_L^{-1} \sqrt{\sigma_G^2 - \mu_G} \), we get

\[ \hat{\mu}_L = \frac{G}{G - \hat{\mu}_C}, \]

\[ \hat{\gamma}_L = \frac{\sqrt{G^2 - \hat{\mu}_C^2}}{G}. \] (3.4)

As long as \( \gamma_L \) is not equal to 0 or close to 0, there is no problem with \( \hat{\gamma}_L \). However, when \( \gamma_L = 0 \) (or close to 0) it may easily happen that \( \sqrt{G^2 - \hat{\mu}_C^2} - \hat{\mu}_C < 0 \) and hence a problem arises with application of (3.4). Note that the case \( \gamma_L = 0 \) corresponds to a fixed parameter of the Poisson distribution of \( G \), a situation which we also want to take into account. In view of the problems with (3.4), indeed it is more convenient to use the parametrization \( \mu_G, \gamma_G \) (see also Remark 2.1). \( \Box \)

4 Behavior of \( E(S - a)^+ \)

The influence of the estimators on \( E(S - a)^+ \) depends on the behavior of \( E(S - a)^+ \) as a function of the parameters \( \mu_C, \gamma_C, \mu_G, \gamma_G, \varepsilon, \lambda \) as well as on the accuracy of the estimators. For instance, if \( E(S - a)^+ \) is a flat function of the parameters \( \mu_C, \gamma_C, \mu_G, \gamma_G, \varepsilon, \lambda \) and the estimators are accurate, the small changes due to estimation will have not much effect. So, these two points have to be considered: how is the fluctuation of \( E(S - a)^+ \) and how accurate are the estimators.

Obviously, the retention \( a \) is not just a given number, but will depend on \( \mu_S = ES \) and \( \sigma_S = \sqrt{\text{var}(S)} \): the larger \( \mu_S \) and \( \sigma_S \), the larger retention \( a \) will be chosen. Defining \( k \) by \( a = \mu_S + k \sigma_S \), or

\[ k = \frac{a - \mu_S}{\sigma_S}, \]

we will assume that \( k \) is chosen in advance, determining the retention \( a \) in "standard units". That means that in our approach \( k \) does not depend on the parameters, while \( a \) does depend on the parameters \( \mu_C, \gamma_C, \mu_G, \gamma_G, \varepsilon, \lambda \) through \( \mu_S \) and \( \sigma_S \).
In order to get insight into the fluctuation of 
\[ E(S-a)^+ = \sigma_S E\left(\frac{S-\mu_S}{\sigma_S} - k\right)^+ \]
we have to simplify \( \sigma_S E(\sigma_S^{-1} (S - \mu_S) - k)^+ \) somewhat, because otherwise no conclusions can be drawn. We apply two simplifications. In the first place, \( \sigma_S E(\sigma_S^{-1} (S - \mu_S) - k)^+ \) is replaced by an approximation, which is simpler, but still sufficiently accurate in the region where we are interested in, see (2.1). This approximation, \( SLP_{app} \), say, concerns the Gamma – Inverse Gaussian \( (G - IG) \) approximation. For a short description of this approximation see the Appendix. That this approximation is indeed accurate in the region considered is shown in the extensive numerical carried out in Lukocius (2007).

Since even then the resulting function is rather complicated, we apply in addition a one step Taylor expansion on the approximation around the true value \((\mu_{C0}, \gamma_{C0}, \mu_{G0}, \gamma_{G0}, \varepsilon_0, \lambda_0)\) of the parameters. We call this function \( SLP_{app1} \), which is given by

\[
SLP_{app1}(\mu_C, \gamma_C, \mu_G, \gamma_G, \varepsilon, \lambda) = SLP_{app}(\mu_{C0}, \gamma_{C0}, \mu_{G0}, \gamma_{G0}, \varepsilon_0, \lambda_0) \\
+ (\mu_C - \mu_{C0}) \frac{\partial}{\partial \mu_C} SLP_{app}(\mu_{C0}, \gamma_{C0}, \mu_{G0}, \gamma_{G0}, \varepsilon_0, \lambda_0) \\
+ \ldots + (\lambda - \lambda_0) \frac{\partial}{\partial \lambda} SLP_{app}(\mu_{C0}, \gamma_{C0}, \mu_{G0}, \gamma_{G0}, \varepsilon_0, \lambda_0). 
\]

The following table gives an impression of the accuracy of \( SLP_{app1} \). Here \( C \) and \( L \) each have a (different) Gamma-distribution and for the true value of the parameters we have the following representative choice: \((\mu_{C0}, \gamma_{C0}, \mu_{G0}, \gamma_{G0}, \varepsilon_0, \lambda_0) = (100000, 0.7, 15, 0.8, 0.03, 400)\), implying \( \gamma_{L0} = 0.76 \). We have \( SLP_{app}(100000, 0.7, 15, 0.8, 0.03, 400) = 1164042, 292282, 56003, 9086 \) for \( k = 0, 1, 2, 3 \), respectively as our starting values. For convenience also the value of \( \gamma_L = \sqrt{\gamma_G^2 - \mu_L^2} \) is given.

**Table 1. Accuracy of approximation \( SLP_{app1} \).**

</table>

This table indicates that the approximation by \( SLP_{app1} \) is sufficiently accurate to proceed with. Note that \( SLP_{app1}(\mu_{C0}, \gamma_{C0}, \mu_{G0}, \gamma_{G0}, \varepsilon_0, \lambda_0) = SLP_{app}(\mu_{C0}, \gamma_{C0}, \mu_{G0}, \gamma_{G0}, \varepsilon_0, \lambda_0) \) and hence Table 1 gives also interesting information on the error in \( SLP_{app}(\tilde{\mu}_C, \gamma_C, \tilde{\mu}_G, \gamma_G, \tilde{\varepsilon}, \tilde{\lambda}) - SLP_{app}(\mu_{C0}, \gamma_{C0}, \mu_{G0}, \gamma_{G0}, \varepsilon_0, \lambda_0) \) due to replacing \( SLP_{app} \) by \( SLP_{app1} \). Hence, further on we concentrate on \( SLP_{app1} \).

The fluctuation of \( SLP_{app1} \) is determined by the coefficients \( \frac{\partial}{\partial \mu_{C0}} SLP_{app}(\mu_{C0}, \gamma_{C0}, \mu_{G0}, \gamma_{G0}, \varepsilon_0, \lambda_0) \ldots \frac{\partial}{\partial \lambda} SLP_{app}(\mu_{C0}, \gamma_{C0}, \mu_{G0}, \gamma_{G0}, \varepsilon_0, \lambda_0) \). To get some impression about the order of magnitude of these coefficients we have calculated them at \((\mu_{C0}, \gamma_{C0}, \mu_{G0}, \gamma_{G0}, \varepsilon_0, \lambda_0) = (100000, 0.7, 15, 0.8, 0.03, 400)\) (again for \( C \) and \( L \) each having a (different) Gamma-distribution and for \( k = 0, 1, 2, 3 \)). The results are given in Table 2.
Table 2. Coefficients of $SLP_{app}$ at $(\mu_C, \gamma_C, \mu_G, \gamma_G, \varepsilon_0, \lambda_0) = (100000, 0.7, 15, 0.8, 0.03, 400)$ for $k = 0, 1, 2, 3.$

In view of the very small coefficients and the fact that $\lambda$ is large it seems better to write the term

$$(\lambda - \lambda_0) \frac{\partial}{\partial \lambda} SLP_{app}(\mu_C, \gamma_C, \mu_G, \gamma_G, \varepsilon_0, \lambda_0)$$

as

$$\frac{\lambda - \lambda_0}{\lambda_0} \lambda_0 \frac{\partial}{\partial \lambda} SLP_{app}(\mu_C, \gamma_C, \mu_G, \gamma_G, \varepsilon_0, \lambda_0).$$

Indeed, in the theory which will be presented next we perform asymptotics for $\lambda \to \infty$ and the appropriate quantity to consider then is $(\lambda - \lambda_0)/\lambda_0,$ see Theorems 5.1 and 5.2. A similar remark applies to $\varepsilon$ (giving rather large coefficients) and hence we will consider $(\varepsilon - \varepsilon_0)/\varepsilon_0.$

5 Behavior of the estimators

We study the behavior of the estimators

$$\hat{\mu}_C, \hat{\gamma}_C, \hat{\mu}_G, \hat{\gamma}_G, \hat{\varepsilon}, \hat{\lambda}.$$ 

These are functions of the vector

$$\left(C + D, C^2 + D^2, G, G^2, \Pi, N\right).$$

The following theorem gives the limiting distribution of this vector. The skewness of a random variable $X$ is denoted by

$$\kappa_3X = \sigma^{-3}E(X - \mu)^3$$

and its kurtosis by

$$\kappa_4X = \sigma^{-4}E(X - \mu)^4 - 3.$$

Remark 5.1 Theorems 5.1, 5.2, 5.3 and 6.1 continue to hold for other distributions of $C$ and $G$ as well, provided that their fourth moments are finite. \hfill $\Box$

Remark 5.2 In the following theorems we assume that $\lambda \to \infty$. That seems to be the natural way, because $\lambda$ is the total expected number of claims, that is the expected number of observations. The other parameters are assumed to be fixed. At first sight it might seem curious that $\mu_C$ is called fixed, while in applications it is very large, for example 100000. However, this parameter is essentially a dummy parameter (although it should be estimated!), see also Section 6. We investigate the effect of the estimation in a relative sense, so to say in $\mu_C$-units and therefore it can be considered as fixed. \hfill $\Box$
Theorem 5.1 Assume that $\lambda \to \infty$ and that $u, \mu_C, \gamma_C, \mu_G, \gamma_G, \varepsilon$ are fixed. Let

$$X_{1\lambda} = \left\{ \frac{C + D}{\mu_C} - 1 \right\} \sqrt{\frac{u \lambda}{\gamma_C}},$$

$$X_{2\lambda} = \left\{ \frac{C^2 + D^2}{\mu_C^2} - (1 + \gamma_C^2) \right\} \sqrt{\frac{u \lambda}{\gamma_C}},$$

$$X_{3\lambda} = \left\{ \frac{G}{\mu_G} - 1 \right\} \sqrt{\frac{\varepsilon u \lambda}{\mu_G}},$$

$$X_{4\lambda} = \left\{ \frac{G^2}{\mu_G} - \mu_G (1 + \gamma_G^2) \right\} \sqrt{\frac{\varepsilon u \lambda}{\mu_G}},$$

$$X_{5\lambda} = \left\{ \frac{H \mu_G}{\varepsilon \lambda} - 1 \right\} \sqrt{\frac{\varepsilon u \lambda}{\mu_G}},$$

$$X_{6\lambda} = \left\{ \frac{N}{\lambda (1 - \varepsilon)} - 1 \right\} \sqrt{u \lambda (1 - \varepsilon)}.$$

Then, as $\lambda \to \infty$,

$$(X_{1\lambda}, X_{2\lambda}, X_{3\lambda}, X_{4\lambda}, X_{5\lambda}, X_{6\lambda}) \to (U_1, U_2, U_3, U_4, U_5, U_6)$$

with

$$(U_1, U_2) \sim N \left(0, 0, \frac{1}{2 + \gamma_C \kappa_{3C}} \frac{\gamma_C^2 (\kappa_{4C} + 2) + 4 \gamma_C \kappa_{3C} + 4}{\gamma_C^2 (\kappa_{4C} + 2) + 4 \gamma_C \kappa_{3C} + 4} \right),$$

$$(U_3, U_4) \sim N \left(0, 0, \frac{\mu_G \gamma_G^2 (2 + \gamma_G \kappa_{3G})}{\mu_G \gamma_G^2 (2 + \gamma_G \kappa_{3G})} \frac{\gamma_G^2 (\kappa_{4G} + 2) + 4 \gamma_G \kappa_{3G} + 4}{\gamma_G^2 (\kappa_{4G} + 2) + 4 \gamma_G \kappa_{3G} + 4} \right),$$

$$U_5 \sim N(0, 1), U_6 \sim N(0, 1)$$

and $(U_1, U_2), (U_3, U_4), U_5, U_6$ independent.

Proof. The proof follows from standard asymptotic normality of random sums, see e.g. Corollary 1 in Teicher (1965), and direct calculation of the involved moments. For instance,

$$\text{cov} \left( \frac{C}{\mu_C \gamma_C}, \frac{C^2}{\mu_C^2 \gamma_C} \right) = \frac{E C^3 - \mu_C E C^2}{\mu_C^3 \gamma_C} = \frac{\kappa_{3C} \gamma_C^3 \mu_C^3 + 3 \mu_C^3 (\gamma_C^2 + 1) - 2 \mu_C^3 - \mu_C^3 (\gamma_C^2 + 1)}{\mu_C^3 \gamma_C} = \kappa_{3C} \gamma_C + 2.$$ 

The role of "n" is played by $\lambda$. The "inflation" of the covariance terms due to different limiting values of the (random) numbers of terms in the sums does not appear here, since the nonzero covariances have the same number of terms. For example, both $C + D$ and $C^2 + D^2$ have as number of terms $N_{tot} + G_{tot}$.

Obviously, $N$, having a $P(\lambda (1 - \varepsilon))$-distribution can be considered as a sum of $\lambda$ independent random variables, each having a $P(1 - \varepsilon)$-distribution, and similarly for $H$. \hfill \square

Remark 5.3 Theorem 5.1 can be applied to $G : P(L)$ with parametrization $\mu_L, \gamma_L$ (provided that the fourth moment of $L$ is finite). We rewrite $X_{3\lambda}$ and $X_{4\lambda}$ as

$$X_{3\lambda} = \left\{ \frac{G}{\mu_L} - 1 \right\} \sqrt{\frac{\varepsilon u \lambda}{\mu_L}},$$

$$X_{4\lambda} = \left\{ \frac{G^2}{\mu_L} - \mu_L (1 + \gamma_L^2) - 1 \right\} \sqrt{\frac{\varepsilon u \lambda}{\mu_L}}.$$
and use formulas like
\[ \gamma_G^2 = \gamma_L^2 + \mu_L^{-1}. \]

We get asymptotic normality with
\[
(U_3, U_4) \sim N \left( 0, 0, \begin{pmatrix}
\gamma_L^2 + \mu_L^{-1} & \mu_L\gamma_L^2 (2 + \gamma_L\kappa_{3L}) \\
\mu_L\gamma_L^2 (2 + \gamma_L\kappa_{3L}) + 2 + 3\gamma_L^2 + \mu_L^{-1} & \mu_L^2 \gamma_L^2 (\kappa_{4L} + 2) + 4\gamma_L\kappa_{3L} + 4
\end{pmatrix} \right).
\]

Obviously, in \( X_{5\lambda} \) we can replace \( \mu_G \) by \( \mu_L \).
\( \square \)

We are interested in \( SLPapp1 \), which is a linear combination of \( \hat{\mu}_C, \ldots, \hat{\lambda} \). The next theorem gives the limiting distribution of such functions.

**Theorem 5.2** Assume that \( \lambda \to \infty \) and that \( u, \mu_C, \gamma_C, \mu_G, \gamma_G, \varepsilon \) are fixed. Let \( c_1, \ldots, c_6 \) be given constants. Define
\[
Z_1 = c_1 \left( \frac{\hat{\mu}_C - \mu_C}{\mu_C} \right) + c_2 (\hat{\gamma}_C - \gamma_C),
\]
\[
Z_2 = c_3 (\hat{\mu}_G - \mu_G) \sqrt{\varepsilon} + c_4 (\hat{\gamma}_G - \gamma_G) \sqrt{\varepsilon} + c_5 \left( \frac{\varepsilon}{\varepsilon} \right) \sqrt{\varepsilon} + c_6 \frac{\lambda - \lambda}{\lambda}
\]
Then, as \( \lambda \to \infty \),
\[
(Z_1, Z_2) \sqrt{u\lambda} \to (V_1, V_2)
\]
with \( V_1, V_2 \) independent and \( V_1 \sim N (0, \tau^2_1) \) and \( V_2 \sim N (0, \tau^2_2) \) with
\[
\tau^2_1 = \gamma_C^2 \{ c_1^2 + c_1c_2 (\kappa_{3C} - 2\gamma_C) + c_2^2 (\gamma_C^2 + \frac{1}{1} \kappa_{4C} + \frac{1}{2} - \gamma_C \kappa_{3C}) \}
\]
and
\[
\tau^2_2 = c_3^2 \mu_G \gamma_G^2 + c_4^2 \mu_G \gamma_G^2 \left( \gamma_G^2 - \gamma_G \kappa_{3G} + \frac{1}{2} \right) + c_5 (1 - \varepsilon) \left( \mu_G (1 - \varepsilon) (1 + \gamma_G^2) + \varepsilon \right)
+ c_6 \left( \mu_G \varepsilon (1 + \gamma_G^2) + 1 - \varepsilon \right)
+ c_3c_4 \mu_G \gamma_G^2 (\kappa_{3G} - 2\gamma_G)
+ 2c_3c_5 (1 - \varepsilon) \mu_G^2 \gamma_G^2
+ 2c_3c_6 \sqrt{\varepsilon} \mu_G \gamma_G^2
+ c_4c_5 \mu_G \gamma_G^2 (1 - \varepsilon) (\kappa_{3G} - 2\gamma_G)
+ c_4c_6 \mu_G \gamma_G^2 \sqrt{\varepsilon} (\kappa_{3G} - 2\gamma_G)
+ 2c_5c_6 \sqrt{\varepsilon} (1 - \varepsilon) \left\{ \mu_G (1 + \gamma_G^2) - 1 \right\}.
\]

**Proof.** We have
\[
\frac{\hat{\mu}_C - \mu_C}{\mu_C} \sqrt{u\lambda} = \gamma_C X_{1\lambda}
\]
and
\[
(\hat{\gamma}_C - \gamma_C) \sqrt{u\lambda} = \left[ \frac{1 + \gamma_C^2 + \gamma_C X_{2\lambda} (u\lambda)^{-1/2} - \left\{ 1 + \gamma_C X_{1\lambda} (u\lambda)^{-1/2} \right\}^2}{1 + \gamma_C X_{1\lambda} (u\lambda)^{-1/2}} - \gamma_C \right] \sqrt{u\lambda}.
\]
It follows from Theorem 5.1 that
\[
\sqrt{1 + \gamma_C^2 + \gamma_C X_{2\lambda}(u\lambda)^{-1/2} - \left(1 + \gamma_C X_{1\lambda}(u\lambda)^{-1/2}\right)^2} \\
= \gamma_C + \frac{1}{2} X_{2\lambda}(u\lambda)^{-1/2} - X_{1\lambda}(u\lambda)^{-1/2} + O_P(\lambda^{-1})
\]
as \lambda \to \infty. Hence, we get
\[
\sqrt{1 + \gamma_C^2 + \gamma_C X_{2\lambda}(u\lambda)^{-1/2} - \left(1 + \gamma_C X_{1\lambda}(u\lambda)^{-1/2}\right)^2} - \gamma_C \\
= \frac{\gamma_C + \frac{1}{2} X_{2\lambda}(u\lambda)^{-1/2} - X_{1\lambda}(u\lambda)^{-1/2} + O_P(\lambda^{-1}) - \gamma_C - \gamma_C^2 X_{1\lambda}(u\lambda)^{-1/2}}{1 + \gamma_C X_{1\lambda}(u\lambda)^{-1/2}} \\
= \frac{1}{2} X_{2\lambda}(u\lambda)^{-1/2} - X_{1\lambda}(u\lambda)^{-1/2} - \gamma_C^2 X_{1\lambda}(u\lambda)^{-1/2} + O_P(\lambda^{-1})
\]
and thus
\[
(\gamma_G - \gamma_C) \sqrt{u\lambda} = \frac{1}{2} X_{2\lambda} - (1 + \gamma_C^2) X_{1\lambda} + O_P\left(\lambda^{-1/2}\right) \tag{5.3}
\]
as \lambda \to \infty. Combination of (5.2) and (5.3) and application of Theorem 5.1 gives
\[
\left\{ \frac{\hat{\mu}_G - \mu_G}{\mu_G} + \epsilon \left(\tilde{\gamma}_G - \gamma_G\right) \right\} \sqrt{u\lambda} \to V_1.
\]
We have
\[
(\hat{\mu}_G - \mu_G) \sqrt{\varepsilon u\lambda} = \mu_G^3 X_{3\lambda} \tag{5.4}
\]
and
\[
G^2 - \tilde{G}^2 = \mu_G^3 \left(1 + \gamma_G^2\right) + \mu_G^3 (\varepsilon u\lambda)^{-1/2} X_{4\lambda} - \left(\mu_G + \mu_G^3 (\varepsilon u\lambda)^{-1/2} X_{3\lambda}\right)^2.
\]
It follows from Theorem 5.1 that
\[
\sqrt{G^2 - \tilde{G}^2} \\
= \mu_G^3 \tilde{G}^2 + \mu_G^3 (\varepsilon u\lambda)^{-1/2} X_{4\lambda} - 2\mu_G^{5/2} (\varepsilon u\lambda)^{-1/2} X_{3\lambda} + O_P(\lambda^{-1}) \\
= \mu_G\gamma_G + \frac{1}{2} \mu_G^{1/2} \gamma_G^{-1} (\varepsilon u\lambda)^{-1/2} X_{4\lambda} - \mu_G^{3/2} \gamma_G^{-1} (\varepsilon u\lambda)^{-1/2} X_{3\lambda} + O_P(\lambda^{-1})
\]
and thus
\[
(\tilde{\gamma}_G - \gamma_G) \sqrt{\varepsilon u\lambda} = \left\{ \frac{\sqrt{G^2 - \tilde{G}^2}}{\mu_G + \mu_G^3 (\varepsilon u\lambda)^{-1/2} X_{3\lambda}} - \gamma_G \right\} \sqrt{\varepsilon u\lambda} \\
= \frac{1}{2} \mu_G^{1/2} \gamma_G^{-1} \left\{ X_{4\lambda} - 2\mu_G \left(1 + \gamma_G^2\right) X_{3\lambda}\right\} + O_P(\lambda^{-1/2})
\]
as \lambda \to \infty. It is seen, cf. e.g. (3.3) that
\[
\tilde{\varepsilon} = \frac{\hat{H}}{\hat{H} + \hat{N}}.
\]
By Theorem 5.1 we get
\[
\hat{H}G = \varepsilon \lambda \left\{1 + \mu_G^{1/2} (\varepsilon u\lambda)^{-1/2} X_{5\lambda}\right\} \left\{1 + \mu_G^{1/2} (\varepsilon u\lambda)^{-1/2} X_{3\lambda}\right\} \tag{5.5}
\]
\[
= \varepsilon \lambda \left\{1 + \mu_G^{1/2} (\varepsilon u\lambda)^{-1/2} (X_{5\lambda} + X_{3\lambda}) + O_P(\lambda^{-1})\right\}.
\]
Together with
\[ N = \lambda (1-\varepsilon) \left[ 1 + \{(1-\varepsilon)u\lambda\}^{-1/2} X_{6\lambda}\right] \] (5.6)
this leads to
\[
\hat{\varepsilon} = \frac{\varepsilon \left[ 1 + \mu_G^{1/2} (\varepsilon u\lambda)^{-1/2} (X_{5\lambda} + X_{3\lambda}) + O_P(\lambda^{-1}) \right]}{\varepsilon \left[ 1 + \mu_G^{1/2} (\varepsilon u\lambda)^{-1/2} (X_{5\lambda} + X_{3\lambda}) + O_P(\lambda^{-1}) \right] + (1-\varepsilon) \left[ 1 + \{(1-\varepsilon)u\lambda\}^{-1/2} X_{6\lambda}\right]} \\
= \varepsilon + (1-\varepsilon)\varepsilon^{1/2} \mu_G^{1/2} (u\lambda)^{-1/2} (X_{5\lambda} + X_{3\lambda}) - \varepsilon (1-\varepsilon)^{1/2} (u\lambda)^{-1/2} X_{6\lambda} + O_P(\lambda^{-1})
\]
and thus
\[
\left( \frac{\hat{\varepsilon} - \varepsilon}{\varepsilon} \right) \sqrt{\varepsilon u\lambda} = (1-\varepsilon) \mu_G^{1/2} (X_{5\lambda} + X_{3\lambda}) - \varepsilon^{1/2} (1-\varepsilon)^{1/2} X_{6\lambda} + O_P(\lambda^{-1/2})
\] (5.7)
as \( \lambda \to \infty \). Finally, we have
\[
\frac{\hat{\lambda} - \lambda}{\lambda} \sqrt{u\lambda} = \left( \frac{HG + N}{\lambda} \right) - 1 \sqrt{u\lambda}.
\]
In view of (5.5) and (5.6) we get
\[
\frac{HG + N}{\lambda} \\
= \varepsilon \left[ 1 + \mu_G^{1/2} (\varepsilon u\lambda)^{-1/2} (X_{5\lambda} + X_{3\lambda}) + O_P(\lambda^{-1}) \right] + (1-\varepsilon) \left[ 1 + \{(1-\varepsilon)u\lambda\}^{-1/2} X_{6\lambda}\right] \\
= 1 + (\varepsilon \mu_G)^{1/2} (u\lambda)^{-1/2} (X_{5\lambda} + X_{3\lambda}) + (1-\varepsilon)^{1/2} (u\lambda)^{-1/2} X_{6\lambda} + O_P(\lambda^{-1})
\]
and hence
\[
\frac{\hat{\lambda} - \lambda}{\lambda} \sqrt{u\lambda} = (\varepsilon \mu_G)^{1/2} (X_{5\lambda} + X_{3\lambda}) + (1-\varepsilon)^{1/2} X_{6\lambda} + O_P(\lambda^{-1/2})
\] (5.8)
as \( \lambda \to \infty \). Combination of (5.4)–(5.8) and application of Theorem 5.1 gives
\[
\left\{ c_3 (\hat{\mu}_G - \mu_G) \sqrt{\varepsilon} + c_4 (\hat{\gamma}_G - \gamma_G) \sqrt{\varepsilon} + c_5 \left( \frac{\hat{\varepsilon} - \varepsilon}{\varepsilon} \right) \sqrt{\varepsilon} + c_6 \frac{\hat{\lambda} - \lambda}{\lambda} \right\} \sqrt{u\lambda} \to V_2.
\]
The asymptotic independence of \( c_1 (\hat{\mu}_C - \mu_C) / \mu_C + c_2 (\hat{\gamma}_C - \gamma_C) \) and \( c_3 (\hat{\mu}_G - \mu_G) \sqrt{\varepsilon} + c_4 (\hat{\gamma}_G - \gamma_G) \sqrt{\varepsilon} + c_5 (\hat{\varepsilon} - \varepsilon) / \sqrt{\varepsilon} + c_6 \left( \frac{\hat{\lambda} - \lambda}{\lambda} \right) / \lambda \) completes the proof. \( \Box \)

Next we apply Theorem 5.2 in order to get an idea of the impact of the estimators on SLP\textsubscript{app1}. The error due to estimation, divided by \( \mu_{C0} \), equals, cf. (4.1),
\[
\mu_{C0}^{-1} \{ SLP\textsubscript{app1} \left( \hat{\mu}_C, \hat{\gamma}_C, \hat{\mu}_G, \hat{\gamma}_G, \hat{\varepsilon}, \hat{\lambda} \right) - SLP\textsubscript{app} (\mu_{C0}, \gamma_{C0}, \mu_{G0}, \gamma_{G0}, \varepsilon_0, \lambda_0) \} \\
= \left( \frac{\hat{\mu}_C - \mu_{C0}}{\mu_{C0}} \right) \frac{\partial}{\partial \mu_C} SLP\textsubscript{app} (\mu_{C0}, \gamma_{C0}, \mu_{G0}, \gamma_{G0}, \varepsilon_0, \lambda_0) \\
+ (\hat{\gamma}_C - \gamma_C) \mu_{C0}^{-1} \frac{\partial}{\partial \gamma_C} SLP\textsubscript{app} (\mu_{C0}, \gamma_{C0}, \mu_{G0}, \gamma_{G0}, \varepsilon_0, \lambda_0) \\
+ \ldots + \left( \frac{\hat{\lambda} - \lambda_0}{\lambda_0} \right) \lambda_0 \mu_{C0}^{-1} \frac{\partial}{\partial \lambda} SLP\textsubscript{app} (\mu_{C0}, \gamma_{C0}, \mu_{G0}, \gamma_{G0}, \varepsilon_0, \lambda_0).
The asymptotic distribution of $\mu^{-1}_{C0}(SLP_{app1}(\hat\mu_C, \hat\gamma_C, \hat\mu_G, \hat\gamma_G, \hat\varepsilon, \hat\lambda_C) - SLP_{app}(\mu_{C0}, \gamma_{C0}, \mu_{G0}, 

$$
\gamma_{G0}, \varepsilon_0, \lambda_0)) \sqrt{\mu\lambda_0}$ is obtained by application of Theorem 5.2 with

$$
c_1 = \frac{\partial}{\partial \mu_C} SLP_{app}(\mu_{C0}, \gamma_{C0}, \mu_{G0}, \gamma_{G0}, \varepsilon_0, \lambda_0),
$$

$$
c_2 = \mu_{C0}^{-1} \frac{\partial}{\partial \gamma_C} SLP_{app}(\mu_{C0}, \gamma_{C0}, \mu_{G0}, \gamma_{G0}, \varepsilon_0, \lambda_0),
$$

$$
c_3 = \varepsilon_0^{-1/2} \mu_{C0}^{-1} \frac{\partial}{\partial \mu_G} SLP_{app}(\mu_{C0}, \gamma_{C0}, \mu_{G0}, \gamma_{G0}, \varepsilon_0, \lambda_0),
$$

$$
c_4 = \varepsilon_0^{-1/2} \mu_{C0}^{-1} \frac{\partial}{\partial \gamma_G} SLP_{app}(\mu_{C0}, \gamma_{C0}, \mu_{G0}, \gamma_{G0}, \varepsilon_0, \lambda_0),
$$

$$
c_5 = \varepsilon_0^{1/2} \mu_{C0}^{-1} \frac{\partial}{\partial \varepsilon} SLP_{app}(\mu_{C0}, \gamma_{C0}, \mu_{G0}, \gamma_{G0}, \varepsilon_0, \lambda_0),
$$

$$
c_6 = \lambda_0 \mu_{C0}^{-1} \frac{\partial}{\partial \lambda} SLP_{app}(\mu_{C0}, \gamma_{C0}, \mu_{G0}, \gamma_{G0}, \varepsilon_0, \lambda_0).
$$

The result is a normal distribution with expectation 0 and variance $\tau_1^2 + \tau_2^2$. Hence, this variance gives an idea of the error due to estimation.

As an example we calculate $\tau_1^2$ and $\tau_2^2$ for $(\mu_{C0}, \gamma_{C0}, \mu_{G0}, \gamma_{G0}, \varepsilon_0, \lambda_0) = (100000, 0.7, 15, 0.8, 0.03, 400)$ and $k = (a - \mu_G)/\sigma_g = 1$ (again with $C$ and $L$ each having a (different) Gamma-distribution). Note that $SLP_{app}(100000, 0.7, 15, 0.8, 0.03, 400) = 292282$ in that case (see Section 4). The values of $c_1, ..., c_6$ are easily obtained from Table 2. We get (for the Gamma distribution it holds that $\kappa_3 = 2\gamma$ and hence the coefficient of $c_1c_2$ equals 0)

$$
c_1^2 \gamma_{C0}^2 = 4.19,
$$

$$
c_1c_2 \gamma_{C0}^2 (\kappa_3 \gamma_{C0} - 2\gamma_{C0}) = 0,
$$

$$
c_2^2 \gamma_{C0}^2 (\gamma_{C0}^2 - 4\kappa_4 \gamma_{C0} + 1/2 - \gamma_{C0} \kappa_3 \gamma_{C0}) = 0.18
$$

and therefore

$$
\tau_1^2 = 4.37.
$$

Using that $L$ has a Gamma-distribution, direct calculation (see also (A7)) gives $\kappa_{3G} = 2\gamma_G - \mu_{G}^{-1} \gamma_{G}^{-1}$ and $\kappa_{4G} = 6\gamma_G^2 - 6 \mu_G + \mu_{G}^{-1} \gamma_{G}^{-2}$. We obtain

$$
c_3^2 \gamma_{C0}^2 \gamma_{G0}^2 = 287.43
$$

$$
\frac{1}{2} c_3^2 \left( \mu_{G0} \gamma_{G0}^4 - \gamma_{C0}^2 + \frac{1}{2} \mu_{G0}^4 + \mu_{G0} \gamma_{C0}^2 \right) = 265.21
$$

$$
c_3^2 (1 - \varepsilon_0) \left\{ \mu_{G0} (1 - \varepsilon_0) (1 + \gamma_{C0}^2) + \varepsilon_0 \right\} = 325.47
$$

$$
c_3^2 \left\{ \mu_{G0} \varepsilon_0 (1 + \gamma_{C0}^2) + 1 - \varepsilon_0 \right\} = 2.84
$$

$$
- c_3 c_4 \mu_{G0} \gamma_{C0} = -25.91
$$

$$
2c_3 c_5 (1 - \varepsilon_0) \mu_{G0} \gamma_{C0}^2 = 381.90
$$

$$
2c_3 c_6 \sqrt{\varepsilon_0} \mu_{G0} \gamma_{C0}^2 = 23.46
$$

$$
- c_4 c_5 \gamma_{G0} (1 - \varepsilon_0) = -17.21
$$

$$
- c_4 c_6 \gamma_{G0} \sqrt{\varepsilon_0} = -1.06
$$

$$
2c_5 c_6 \sqrt{\varepsilon_0} (1 - \varepsilon_0) \left\{ \mu_{G0} (1 + \gamma_{C0}^2) - 1 \right\} = 38.31
$$

and hence

$$
\tau_2^2 = 1280.43.
$$

This example is really illuminating. It is clearly seen that the contribution of estimating $\mu_C$ and $\gamma_C$ is not very high: $\tau_1^2$ is much smaller than $\tau_2^2$. The reason is that we have a lot of observations.
for estimating $\mu_C$ and $\gamma_C$. Typical values for $u$ and $\lambda$ are values like 7 and 400, respectively. That means about 2800 observations to estimate the parameters of the common distribution of the $C_i$ and $D_{jk}$. Due to this large number of observations, these estimators are very accurate. Similarly, estimating $\lambda$ gives also a not very high contribution to the variance $\tau_3^2 + \tau_4^2$. That is seen from the various terms contributing to $\tau_2^2$. The terms in which estimating $\lambda$ is involved, that is the terms where $c_6$ appears, are much smaller than the other terms.

This leads to the following

**Conclusion.** The estimation error is dominated by the estimation of the parameters related to the common risk, that is by estimating $\mu_G, \gamma_G$ and $\varepsilon$. Therefore, the parameters of the distribution of the $C_i$ and $D_{jk}, \mu_C$ and $\gamma_C$, and also $\lambda$ can in fact considered to be known.

**Remark 5.4** Theorem 5.2 can be applied to $G : P(L)$ with parametrization $\mu_L, \gamma_L$ (provided that the fourth moment of $L$ is finite), replacing $c_3 (\hat{\mu}_G - \mu_G) \sqrt{\varepsilon} + c_4 (\hat{\gamma}_G - \gamma_G) \sqrt{\varepsilon}$ by $c_3 (\hat{\mu}_L - \mu_L) \sqrt{\varepsilon} + c_4 (\hat{\gamma}_L - \gamma_L) \sqrt{\varepsilon}$ and $\tau_2^2$ by

$$
\tau_2^2 = c_3^2 (\mu_L^2 \gamma_L^2 + \mu_L^3)
+ c_3^2 \left\{ \mu_L \gamma_L^2 \left( \gamma_L - \gamma_L \kappa_3L + \frac{1}{4} \kappa_4L + \frac{1}{2} \right) - \gamma_L^2 + \gamma_L \kappa_3L + 1 + \frac{1}{2} \mu_L^{-1} (1 + \gamma_L^2) \right\}
+ c_3^2 (1 - \varepsilon) \left\{ \mu_L (1 - \varepsilon) (1 + \gamma_L^2) + 1 \right\}
+ c_3^2 \left\{ \mu_L \varepsilon (1 + \gamma_L^2) + 1 \right\}
+ c_3 c_4 \mu_L^2 \gamma_L^2 (\kappa_3L - 2 \gamma_L)
+ 2 c_3 c_5 (1 - \varepsilon) (\mu_L^2 \gamma_L^2 + \mu_L)
+ 2 c_3 c_6 \sqrt{\varepsilon} (\mu_L^2 \gamma_L^2 + \mu_L)
+ c_4 c_5 \mu_L \gamma_L^2 (1 - \varepsilon) (\kappa_3L - 2 \gamma_L)
+ c_4 c_6 \mu_L \gamma_L^2 \sqrt{\varepsilon} (\kappa_3L - 2 \gamma_L)
+ 2 c_5 c_6 \mu_L \sqrt{\varepsilon} (1 - \varepsilon) (1 + \gamma_L^2).
$$

So, in the sequel $\mu_G, \gamma_C$ and $\lambda$ are assumed to be known, while $\varepsilon, \mu_G = \mu_L$ and $\gamma_G$ or $\gamma_L$ are estimated by

$$
\hat{\varepsilon} = \frac{G_{tot}}{G_{tot} + N_{tot}},
\hat{\mu}_G = \hat{\mu}_L = \overline{C},
\hat{\gamma}_G = \sqrt{\frac{G^2 - \overline{C}^2}{G}}, \hat{\gamma}_L = \sqrt{\frac{G^2 - \overline{C}^2}{G}}
$$

with

$$
G_{tot} = \sum_{t=1}^u \sum_{k=1}^{h_t} G_{kt}, H_{tot} = \sum_{t=1}^u H_t, N_{tot} = \sum_{t=1}^u N_t,
\overline{G} = \frac{1}{H_{tot}} \sum_{t=1}^u \sum_{k=1}^{h_t} G_{kt}, \overline{G}^2 = \frac{1}{H_{tot}} \sum_{t=1}^u \sum_{k=1}^{h_t} G_{kt}^2.
$$

Writing $SLP(\hat{\mu}_G, \hat{\gamma}_C, \hat{\mu}_G, \hat{\gamma}_G, \hat{\varepsilon}, \hat{\lambda})$ for the estimator of the stop-loss premium $E(S - a)^+$, we now have the following result.
Theorem 5.3 Let \((\mu_{C0}, \gamma_{C0}, \mu_{G0}, \gamma_{G0}, \varepsilon_0, \lambda_0)\) be the true value of the parameters. Then
\[
SLP(\hat{\mu}_C, \hat{\gamma}_C, \hat{\mu}_G, \hat{\gamma}_G, \hat{\varepsilon}, \hat{\lambda}) \approx SLP_{app} \left( \mu_{C0}, \gamma_{C0}, \mu_{G0}, \gamma_{G0}, \varepsilon_0, \lambda_0 \right)
\]
and
\[
\mu_{C0}^{-1} \left\{ SLP_{app} \left( \mu_{C0}, \gamma_{C0}, \mu_{G0}, \gamma_{G0}, \varepsilon_0, \lambda_0 \right) - SLP_{app} \left( \mu_{C0}, \gamma_{C0}, \mu_{G0}, \gamma_{G0}, \varepsilon_0, \lambda_0 \right) \right\} \sqrt{u \lambda \varepsilon_0} \to V
\]
as \(\lambda \to \infty\), with \(V \sim N \left( 0, \tau^2 \right)\), in which
\[
\tau^2 = c_3^2 \mu_{G0} \gamma_{G0}^2
\]
\[
+ c_2^2 \mu_{G0} \gamma_{G0}^2 \left( \gamma_{G0}^2 - \gamma_{G0} \kappa_{3G} + \frac{1}{4} \kappa_{4G} + \frac{1}{\lambda} \right)
\]
\[
+ c_2^2 \left( 1 - \varepsilon \right) \left( \mu_{G0} \left( 1 - \varepsilon \right) \left( 1 + \gamma_{G0}^2 \right) + \varepsilon \right)
\]
\[
+ c_3^2 \mu_{G0} \gamma_{G0}^2 \left( \kappa_{3G} - 2 \gamma_{G0} \right)
\]
\[
+ 2c_3 \gamma_{G0} \left( 1 - \varepsilon \right) \mu_{G0} \gamma_{G0}^2
\]
\[
+ c_4^2 \mu_{G0} \gamma_{G0}^2 \left( 1 - \varepsilon \right) \left( \kappa_{3G} - 2 \gamma_{G0} \right),
\]
where
\[
c_3 = \mu_{C0}^{-1} \frac{\partial}{\partial \mu_{G0}} SLP_{app} \left( \mu_{C0}, \gamma_{C0}, \mu_{G0}, \gamma_{G0}, \varepsilon_0, \lambda_0 \right),
\]
\[
c_4 = \mu_{C0}^{-1} \frac{\partial}{\partial \gamma_{G0}} SLP_{app} \left( \mu_{C0}, \gamma_{C0}, \mu_{G0}, \gamma_{G0}, \varepsilon_0, \lambda_0 \right),
\]
\[
c_5 = \varepsilon_0 \mu_{C0}^{-1} \frac{\partial}{\partial \varepsilon} SLP_{app} \left( \mu_{C0}, \gamma_{C0}, \mu_{G0}, \gamma_{G0}, \varepsilon_0, \lambda_0 \right).
\]

Proof. The limiting result follows directly from Theorem 5.2, because
\[
\mu_{C0}^{-1} \left\{ SLP_{app} \left( \mu_{C0}, \gamma_{C0}, \mu_{G0}, \gamma_{G0}, \varepsilon_0, \lambda_0 \right) - SLP_{app} \left( \mu_{C0}, \gamma_{C0}, \mu_{G0}, \gamma_{G0}, \varepsilon_0, \lambda_0 \right) \right\}
\]
\[
= c_3 \left( \mu_{G0} - \mu_{C0} \right) + c_4 \left( \gamma_{G0} - \gamma_{C0} \right) + c_5 \frac{\gamma_{G0} - \gamma_{C0}}{\varepsilon_0}
\]
with \(c_3, c_4, c_5\) given by (5.11). (Note that here we have used in the formulation of the theorem \(\sqrt{u \lambda \varepsilon_0}\) instead of \(\sqrt{u \lambda}\), because the expected number of special claims equals \(u \lambda \varepsilon_0\).) \(\square\)

Remark 5.5 Theorem 5.3 can be applied to \(G : P(L)\) with parametrization \(\mu_L, \gamma_L\) (provided that the fourth moment of \(L\) is finite), replacing \(SLP(\hat{\mu}_C, \hat{\gamma}_C, \hat{\mu}_G, \hat{\gamma}_G, \hat{\varepsilon}, \hat{\lambda})\), \(SLP_{app}(\mu_{C0}, \gamma_{C0}, \mu_{G0}, \gamma_{G0}, \varepsilon_0, \lambda_0)\) by \(SLP(\tilde{\mu}_C, \tilde{\gamma}_C, \tilde{\mu}_G, \tilde{\gamma}_G, \tilde{\varepsilon}, \tilde{\lambda})\), \(SLP_{app}(\mu_{C0}, \gamma_{C0}, \mu_{G0}, \gamma_{G0}, \varepsilon_0, \lambda_0)\) and \(SLP_{app}(\mu_{C0}, \gamma_{C0}, \mu_{G0}, \gamma_{G0}, \varepsilon_0, \lambda_0)\) by \(SLP(\tilde{\mu}_C, \tilde{\gamma}_C, \tilde{\mu}_G, \tilde{\gamma}_G, \tilde{\varepsilon}, \tilde{\lambda})\), \(SLP_{app}(\mu_{C0}, \gamma_{C0}, \mu_{G0}, \gamma_{G0}, \varepsilon_0, \lambda_0)\), respectively, and \(\tau^2\) by
\[
\tau^2 = c_3^2 \left( \mu_{L0} \gamma_{L0}^2 + \mu_{L0}^2 \right)
\]
\[
+ c_2^2 \mu_{L0} \gamma_{L0}^2 \left( \gamma_{L0}^2 - \gamma_{L0} \kappa_{3L0} + \frac{1}{4} \kappa_{4L0} + \frac{1}{2} \right) \gamma_{L0}^2 - \gamma_{L0} \kappa_{3L0} + 1 + \frac{1}{2} \mu_{L0}^{-1} \left( 1 + \gamma_{L0}^{-2} \right)
\]
\[
+ c_2^2 \left( 1 - \varepsilon_0 \right) \left( \mu_{L0} \left( 1 - \varepsilon_0 \right) \left( 1 + \gamma_{L0}^2 \right) + \varepsilon_0 \right)
\]
\[
+ c_3^2 \mu_{L0} \gamma_{L0}^2 \left( \kappa_{3L0} - 2 \gamma_{L0} \right)
\]
\[
+ 2c_3 \gamma_{L0} \left( 1 - \varepsilon_0 \right) \mu_{L0} \gamma_{L0}^2
\]
\[
+ c_4^2 \mu_{L0} \gamma_{L0}^2 \left( 1 - \varepsilon_0 \right) \left( \kappa_{3L0} - 2 \gamma_{L0} \right),
\]
where
\[
c_3 = \mu_{C0}^{-1} \frac{\partial}{\partial \mu_L} \text{SLP}_{app}(\mu_{C0}, \gamma_{C0}, \mu_{L0}, \gamma_{L0}, \varepsilon_0, \lambda_0),
\]
\[
c_4 = \mu_{C0}^{-1} \frac{\partial}{\partial \gamma_L} \text{SLP}_{app}(\mu_{C0}, \gamma_{C0}, \mu_{L0}, \gamma_{L0}, \varepsilon_0, \lambda_0),
\]
\[
c_5 = \varepsilon_0 \mu_{C0}^{-1} \frac{\partial}{\partial \varepsilon} \text{SLP}_{app}(\mu_{C0}, \gamma_{C0}, \mu_{L0}, \gamma_{L0}, \varepsilon_0, \lambda_0).
\]

6 Effect of estimation, protection

Having established readily applicable formulas for the estimation effects, we investigate the impact of the estimation on the stop-loss premium \(E(S-a)^+\). We start with an example. Let the true values of the parameters be equal to \((\mu_{C0}, \gamma_{C0}, \mu_{G0}, \gamma_{G0}, \varepsilon_0, \lambda_0) = (100000, 0.7, 15, 0.8, 0.03, 400)\) and \(k = (a - \mu_S)/\sigma_S = 1\). Let \(C\) and \(L\) each have a (different) Gamma-distribution. As we have seen, see Section 4, \(\text{SLP}_{app}(100000, 0.7, 15, 0.8, 0.03, 400) = 292282\) in that case. We may for example ask: what is the probability that \(\text{SLP}_{app1}(\mu_{C0}, \gamma_{C0}, \hat{\mu}_G, \hat{\gamma}_G, \hat{\varepsilon}, \lambda_0)\) is smaller than 200000, that is an error of more than 92282? We apply Theorem 5.3. Direct calculation gives \(\tau^2 = 36.51\) and hence, with \(V \sim N(0, 36.51)\) and \(\Phi\) the standard normal distribution function,
\[
P(\text{SLP}_{app1}(\mu_{C0}, \gamma_{C0}, \hat{\mu}_G, \hat{\gamma}_G, \hat{\varepsilon}, \lambda_0) < 200000)
= P(10^{-5}\{\text{SLP}_{app1}(\mu_{C0}, \gamma_{C0}, \hat{\mu}_G, \hat{\gamma}_G, \hat{\varepsilon}, \lambda_0) - 292282\} \sqrt{12u} < 10^{-5}(200000 - 292282) \sqrt{12u})
\approx P(V > -3.20\sqrt{u}) = \Phi(-0.53\sqrt{u}).
\]

Taking only one year, that is \(u = 1\), we see that with a probability as large as 30% we get an estimated value smaller than 200000, while in fact it should have been 292282. This makes clear that indeed one year is not enough. The reason for this is of course that in one year the expected number of groups is (in this case) only \(\varepsilon/\mu_G = 12/15 = 0.8\). This makes the estimation of \(\mu_G, \gamma_G\) and \(\varepsilon\) very inaccurate. When taking \(u = 7\), the probability reduces from 30% to 8%.

We see from the example that the estimation effect may be considerable and we may want to protect ourselves against the estimation error, in the sense of confidence bounds for \(\text{SLP}_{app}\). The following theorem deals with such a protection.

**Theorem 6.1** Let \((\mu_{C0}, \gamma_{C0}, \mu_{G0}, \gamma_{G0}, \varepsilon_0, \lambda_0)\) be the true value of the parameters. Then
\[
\lim_{\lambda \to \infty} P(\text{SLP}_{app}(\mu_{C0}, \gamma_{C0}, \mu_{G0}, \gamma_{G0}, \varepsilon_0, \lambda_0) < UB(\alpha)) = 1 - \alpha,
\]
\[
\lim_{\lambda \to \infty} P(\text{SLP}_{app}(\mu_{C0}, \gamma_{C0}, \mu_{G0}, \gamma_{G0}, \varepsilon_0, \lambda_0) > LB(\alpha)) = 1 - \alpha,
\]
\[
\lim_{\lambda \to \infty} P(\text{LB}(\alpha/2) < \text{SLP}_{app}(\mu_{C0}, \gamma_{C0}, \mu_{G0}, \gamma_{G0}, \varepsilon_0, \lambda_0) < UB(\alpha/2)) = 1 - \alpha
\]

with
\[
UB(\alpha) = \text{SLP}_{app1}(\mu_{C0}, \gamma_{C0}, \hat{\mu}_G, \hat{\gamma}_G, \hat{\varepsilon}, \lambda_0) + \Phi^{-1}(1 - \alpha)(\hat{\varepsilon} u \lambda_0)^{-1/2}\hat{\tau}_{\mu_{C0}},
\]
\[
LB(\alpha) = \text{SLP}_{app1}(\mu_{C0}, \gamma_{C0}, \hat{\mu}_G, \hat{\gamma}_G, \hat{\varepsilon}, \lambda_0) - \Phi^{-1}(1 - \alpha)(\hat{\varepsilon} u \lambda_0)^{-1/2}\hat{\tau}_{\mu_{C0}},
\]

where \(\hat{\tau} = \sqrt{\hat{\tau}^2}\) and \(\hat{\tau}^2\) is given in (5.10) and (5.11) with \(\mu_{G0}, \gamma_{G0}, \varepsilon_0\) replaced by their estimators \(\hat{\mu}_G, \hat{\gamma}_G, \hat{\varepsilon}\) (also in \(c_3, c_4, c_5, \kappa_{3G0}\) and \(\kappa_{4G0}\)).
Proof. It is easily seen, cf. e.g. Theorem 5.2, that \( \hat{\mu}_G, \hat{\gamma}_G, \hat{\varepsilon} \) are consistent estimators of \( \mu_G, \gamma_G, \varepsilon \) and hence \( \hat{\tau} \to^P \tau \) as \( \lambda_0 \to \infty \). Application of Theorem 5.3 therefore yields

\[
(\hat{\tau}_{\mu_0}^{-1} \{ SLP_{app} (\mu_{\mu_0}, \gamma_{\mu_0}, \hat{\mu}_G, \hat{\gamma}_G, \hat{\varepsilon}, \lambda_0) - SLP_{app} (\mu_{\mu_0}, \gamma_{\mu_0}, \mu_G, \gamma_G, \varepsilon_0, \lambda_0) \}) \sqrt{\hat{\varepsilon}_0} \lambda_0 \to U
\]

with \( U \sim N(0, 1) \). This implies, writing temporarily \( \hat{S} = SLP_{app} (\mu_{\mu_0}, \gamma_{\mu_0}, \hat{\mu}_G, \hat{\gamma}_G, \hat{\varepsilon}, \lambda_0) \) and noting that \( SLP_{app} (\mu_{\mu_0}, \gamma_{\mu_0}, \mu_G, \gamma_G, \varepsilon_0, \lambda_0) = SLP_{app} (\mu_{\mu_0}, \gamma_{\mu_0}, \mu_G, \gamma_G, \varepsilon_0, \lambda_0) \),

\[
P(SLP_{app} (\mu_{\mu_0}, \gamma_{\mu_0}, \mu_G, \gamma_G, \varepsilon_0, \lambda_0) < UB (\alpha))
= P(SLP_{app} (\mu_{\mu_0}, \gamma_{\mu_0}, \mu_G, \gamma_G, \varepsilon_0, \lambda_0) < \hat{S} + \Phi^{-1} (1 - \alpha) (\hat{\varepsilon}_0 \lambda_0)^{-1/2} \hat{\tau}_{\mu_0})
= P((\hat{\tau}_{\mu_0})^{-1} \{ \hat{S} - SLP_{app} (\mu_{\mu_0}, \gamma_{\mu_0}, \mu_G, \gamma_G, \varepsilon_0, \lambda_0) \}) \sqrt{\hat{\varepsilon}_0} \lambda_0 > -\Phi^{-1} (1 - \alpha)
\to P(U > -\Phi^{-1} (1 - \alpha)) = 1 - \alpha,
\]

thus giving the first result. The other statements are obtained in a similar way. \( \square \)

Remark 6.1 Theorem 6.1 can be applied to \( G : P(L) \) with parametrization \( \mu_L, \gamma_L \) (provided that the fourth moment of \( L \) is finite), replacing \( SLP_{app} (\mu_{\mu_0}, \gamma_{\mu_0}, \mu_G, \gamma_G, \varepsilon_0, \lambda_0) \) and \( SLP_{app} (\mu_{\mu_0}, \gamma_{\mu_0}, \hat{\mu}_G, \hat{\gamma}_G, \hat{\varepsilon}, \lambda_0) \) by \( SLP_{app} (\mu_{\mu_0}, \gamma_{\mu_0}, \mu_L, \gamma_L, \varepsilon_0, \lambda_0) \) and \( SLP_{app} (\mu_{\mu_0}, \gamma_{\mu_0}, \hat{\mu}_L, \hat{\gamma}_L, \hat{\varepsilon}, \lambda_0) \), respectively, and \( \hat{\tau} \) by the estimated version of (5.12) and (5.13). \( \square \)

Remember that the contribution of estimating \( \mu_G, \gamma_G \) and \( \lambda \) is very small compared to that of estimating \( \mu_{\mu_0}, \gamma_{\mu_0} \) and \( \varepsilon \). Therefore, we assume in Theorem 6.1 again \( \mu_{\mu_0}, \gamma_{\mu_0}, \lambda_0 \) to be known. Obviously, in practice one should insert the estimators \( \hat{\mu}_G, \hat{\gamma}_G \) and \( \hat{\lambda} \) in the upper and lower bounds \( UB (\alpha) \) and \( LB (\alpha) \).

In Figures 1–3 some examples are presented of the extra amount due to protection against estimation and the effect of dependence in these situations. Figures 1a–3a show the relative difference between the independent case and the dependence one. Let \( C \) and \( L \) each have a (different) Gamma-distribution. We take \( \gamma_{C0} = 0.4 \) or 1.2, \( \mu_{C0} = 5, 10 \) or 15, \( \gamma_{C0} = 0.5 \) or 1, \( \varepsilon_0 = 0.03 \) and \( \lambda_0 = 400 \). Obviously the independence case is obtained by taking \( \varepsilon = 0 \). The relative difference is defined by

\[
\frac{SLP_{app} (\mu_{\mu_0}, \gamma_{\mu_0}, \mu_G, \gamma_G, \varepsilon_0, \lambda_0) - SLP_{app} (\mu_{\mu_0}, \gamma_{\mu_0}, \mu_G, \gamma_G, 0, \lambda_0)}{SLP_{app} (\mu_{\mu_0}, \gamma_{\mu_0}, \mu_G, \gamma_G, 0, \lambda_0)}
= SLP_{app} (\mu_{\mu_0}, \gamma_{\mu_0}, \mu_G, \gamma_G, 0, \lambda_0) - SLP_{app} (\mu_{\mu_0}, \gamma_{\mu_0}, \mu_G, \gamma_G, \varepsilon_0, \lambda_0)
\]

where \( SLP \) denotes the (approximated) stop-loss premium \( SLP_{app} (\mu_{\mu_0}, \gamma_{\mu_0}, \mu_G, \gamma_G, \varepsilon_0, \lambda_0) \) under dependence and \( SLP_{app} (\mu_{\mu_0}, \gamma_{\mu_0}, \mu_G, \gamma_G, 0, \lambda_0) \), the (approximated) stop-loss premium under independence. For a fair comparison we take both for the independence model and the dependence one the same retentions

\[
a = \mu_S + k \sigma_{SI}
\]

with \( k = 0, ..., 3 \) and \( \sigma_{SI} = \mu_C \sqrt{\lambda (1 + \gamma^2_C)} \), the standard deviation of \( S \) for the independence model (see also the Appendix).

Figures 1b–3b show the extra amount due to protection against estimation, also measured in a relative way by taking

\[
\frac{UB (\alpha) - SLP_{app} (\mu_{\mu_0}, \gamma_{\mu_0}, \mu_G, \gamma_G, \varepsilon_0, \lambda_0)}{SLP_{app} (\mu_{\mu_0}, \gamma_{\mu_0}, \mu_G, \gamma_G, \varepsilon_0, \lambda_0)}
\]

with in \( UB (\alpha) \) the estimators \( \hat{\mu}_G, \hat{\gamma}_G, \hat{\varepsilon} \) and \( \hat{\tau} \) replaced by \( \mu_G, \gamma_G, \varepsilon_0 \) and \( \sqrt{\hat{\tau}^2} \), respectively. We take \( \alpha = 0.1 \) and \( u = 7 \). It is easily seen (see also at the end of this section) that both measures do not depend on \( \mu_{\mu_0} \).
**Figure 1a.** Relative difference between dependence and independence \((\text{SLP}/\text{SLP}_I) - 1\) with \(\mu_G = 5, \gamma_C = 0.4, 1.2, \gamma_G = 0.5, 1\) and 
\[a = \mu_S + k\sigma_{SI}.\]

**Figure 1b.** Relative extra amount due to estimation \((UB(\alpha)/\text{SLP}) - 1\) with 
\[\alpha = 0.1, \mu_G = 5, \gamma_C = 0.4, 1.2, \gamma_G = 0.5, 1\] and 
\[a = \mu_S + k\sigma_{SI}.\]

**Figure 2a.** Relative difference between dependence and independence \((\text{SLP}/\text{SLP}_I) - 1\) with \(\mu_G = 10, \gamma_C = 0.4, 1.2, \gamma_G = 0.5, 1\) and 
\[a = \mu_S + k\sigma_{SI}.\]

**Figure 2b.** Relative extra amount due to estimation \((UB(\alpha)/\text{SLP}) - 1\) with 
\[\alpha = 0.1, \mu_G = 10, \gamma_C = 0.4, 1.2, \gamma_G = 0.5, 1\] and 
\[a = \mu_S + k\sigma_{SI}.\]
Note that the order of the displayed cases is slightly different in the figures a and b: for instance, for $\mu_{G0} = 5$ (Figures 1a, b) the relative difference between dependence and independence is higher for $\gamma_C = 0.4$, $\gamma_G = 0.5$ than for $\gamma_C = 1.2$, $\gamma_G = 1$, while their order w.r.t. the relative extra amount due to protection against estimation is reversed.

Figures 1–3 affirm that ignoring dependence may lead to very large errors (up to 4294% in Figure 3). But also the additional step due to protection against estimation is large (up to 138% in Figure 3). A numerical example may illustrate this. Consider again the example with true values of the parameters being equal to $(\mu_{C0}, \gamma_{C0}, \mu_{G0}, \gamma_{G0}, \varepsilon_0, \lambda_0) = (100000, 0.7, 15, 0.8, 0.03, 400)$. Take $k = 1$ and hence $a = \mu_S + k\sigma_{SI} = 4 \times 10^7 + 2561250 = 42561250$. If we ignore the dependence structure we get $SLP_{app}(100000, 0.7, 15, 0.8, 0.03, 400) = 211277$. If we take into account the dependence without protection against estimation we get $SLP_{app}(100000, 0.7, 15, 0.8, 0.03, 400) = 382006$. If we add the protection (taking $\tilde{\mu}_G = \mu_{G0} = 15, \tilde{\gamma}_G = \gamma_{G0} = 0.8, \tilde{\varepsilon} = \varepsilon_0 = 0.03, \tilde{\tau} = \sqrt{\tau^2}$) we get $UB(0.1) = 476596$.

The upper and lower bounds $UB(\alpha)$ and $LB(\alpha)$ contain the term $\tilde{\tau}_{\mu_{C0}}$. As this quantity is the less transparent part of $UB(\alpha)$ and $LB(\alpha)$, we will discuss it now. It is seen in the Appendix that

$$SLP_{app}(\mu_C, \gamma_C, \mu_G, \gamma_G, \varepsilon, \lambda) = \mu_C \frac{d}{d\mu_G} SLP_{app}(1, \gamma_{C0}, \mu_{G0}, \gamma_{G0}, \varepsilon_0, \lambda_0),$$

in view of (5.11) this implies

$$c_3 = \frac{\partial}{\partial \mu_G} SLP_{app}(1, \gamma_{C0}, \mu_{G0}, \gamma_{G0}, \varepsilon_0, \lambda_0),$$

$$c_4 = \frac{\partial}{\partial \gamma_G} SLP_{app}(1, \gamma_{C0}, \mu_{G0}, \gamma_{G0}, \varepsilon_0, \lambda_0),$$

$$c_5 = \varepsilon_0 \frac{\partial}{\partial \varepsilon} SLP_{app}(1, \gamma_{C0}, \mu_{G0}, \gamma_{G0}, \varepsilon_0, \lambda_0).$$
Therefore, see (4.1), using

\[
SLP_{\text{app1}}(\mu_{C0}, \gamma_{C0}, \mu_{G0}, \gamma_{G0}, \varepsilon_0, \lambda_0) = SLP_{\text{app}}(\mu_{C0}, \gamma_{C0}, \mu_{G0}, \gamma_{G0}, \varepsilon_0, \lambda_0)
\]

\[
= \mu_{C0}SLP_{\text{app}}(1, \gamma_{C0}, \mu_{G0}, \gamma_{G0}, \varepsilon_0, \lambda_0),
\]

we get

\[
UB(\alpha) = \mu_{C0}\{SLP_{\text{app1}}(1, \gamma_{C0}, \hat{\mu}_G, \hat{\gamma}_G, \varepsilon, \lambda_0) + \Phi^{-1}(1 - \alpha)(\varepsilon \mu \lambda_0)^{-1/2}\}
\]

\[
LB(\alpha) = \mu_{C0}\{SLP_{\text{app1}}(1, \gamma_{C0}, \hat{\mu}_G, \hat{\gamma}_G, \varepsilon, \lambda_0) - \Phi^{-1}(1 - \alpha)(\varepsilon \mu \lambda_0)^{-1/2}\}.
\]

So, we see that indeed \(\mu_{C0}\) is a kind of dummy parameter.

In the special case with \(L\) having a Gamma distribution, \(\kappa_{3G} = 2\gamma_G - \mu_G^{-1}\gamma_G^{-1}, \kappa_{4G} = 6\gamma_G^2 - 6\mu_G^{-1} + \mu_G^{-2}\gamma_G^{-2}\) and thus \(\tau^2\) reduces to

\[
\tau^2 = \frac{1}{2\mu_G} \gamma_G^2
\]

\[
+ \frac{1}{2\mu_G} \left( \mu_G \gamma_G^4 - \gamma_G^2 + \frac{1}{2\mu_G} + \mu_G \gamma_G^2 \right)
\]

\[
+ c_2 (1 - \varepsilon) \{\mu_G (1 - \varepsilon) (1 + \gamma_G^2) + \varepsilon\}
\]

\[
- c_3 \mu_G \gamma_G
\]

\[
+ 2c_3c_5 (1 - \varepsilon) \mu_G^2 \gamma_G^2
\]

\[
- c_4 c_5 \gamma_G (1 - \varepsilon).
\]

For illustrative purposes we show the behavior of \(\tau^2\) in (6.1) as a function of \(\varepsilon\) (with \((\mu_C, \gamma_C, \mu_G, \gamma_G, \lambda, k) = (100000, 0.7, 15, 0.8, 400, 1)\) keeping fixed). Note that \(c_3, c_4, c_5\) depend on \(\varepsilon\) in a complicated way. It is clearly seen in Figure 4 that \(\tau^2\) tends to 0 if \(\varepsilon \to 0\).

**Figure 4.** Behavior of \(\tau^2(\mu_C, \gamma_C, \mu_G, \gamma_G, \varepsilon, \lambda, k)\) as \(\varepsilon \to 0\) with

\((\mu_C, \gamma_C, \mu_G, \gamma_G, \lambda) = (100000, 0.7, 15, 0.8, 400)\) and \(k = (a - \mu_S) / \sigma_S = 1.\)
Appendix Approximations

Here we present three approximations: the Gamma approximation, the Inverse Gaussian (IG) approximation and the Gamma – Inverse Gaussian (G – IG) approximation. For the parameter range and distributions under consideration (see Section 2) the G – IG approximation works well and is best among the three approximations, see Lukocius (2007) for more details. Therefore, the G – IG approximation is recommended. Note that one has to be careful with extending this conclusion outside the parameter range or for other distributions than considered here.

Gamma approximation
A shifted Gamma distribution is fitted such that the first three cumulants coincide with those of $S$. The density of the Gamma distribution with parameters $\alpha$ and $\beta$ (for short: Gamma($\alpha, \beta$)) is given by

$$f_G(x; \alpha, \beta) = \frac{x^{\alpha-1}e^{-\beta x}}{\Gamma(\alpha)}.$$

We approximate $S$ by $T$ such that $T - x_0$ is Gamma($\alpha, \beta$), where $x_0$, $\alpha$ and $\beta$ are selected such that the first three cumulants of $T$ and $S$ coincide. This is achieved by taking

$$\alpha = \left(\frac{2}{\kappa_3 S}\right)^2, \beta = \frac{2}{\sigma S \kappa_3 S} \text{ and } x_0 = \mu_S - \frac{2\sigma S}{\kappa_3 S}.$$

Noting that $a = \mu_S + k\sigma_S$, it leads to the approximation

$$E_G(S - a)^+ = \sigma S E_G \left(\frac{S - \mu_S}{\sigma S} - k\right)^+$$

$$= \sigma S \left\{ \frac{2}{\kappa_3 S} F_G \left(k + \frac{2}{\kappa_3 S};\frac{4}{\kappa_3 S} + 1, \frac{2}{\kappa_3 S}\right) - \left(k + \frac{2}{\kappa_3 S} \frac{2}{\kappa_3 S}\right)\right\},$$

where

$$F_G(x; \alpha, \beta) = 1 - F_G(x; \alpha, \beta)$$

and where $F_G(x; \alpha, \beta)$ is the distribution function of the Gamma distribution with parameters $\alpha$ and $\beta$.

IG approximation
The density of the IG-distribution with parameters $\alpha$ and $\beta$ (for short: IG($\alpha, \beta$)) is given by

$$f_{IG}(x; \alpha, \beta) = \alpha(2\pi \beta)^{-1/2}x^{-3/2} \exp \left\{ -\frac{\alpha - \beta x}{2\beta x} \right\}.$$

For the IG approximation (see Chaubey et al. (1998)) we approximate $S$ by $T$ such that $T - x_0$ is IG($\alpha, \beta$), where $x_0$, $\alpha$ and $\beta$ are selected such that the first three cumulants of $T$ and $S$ coincide. This is achieved by taking

$$\alpha = \left(\frac{3}{\kappa_3 S}\right)^2, \beta = \frac{3}{\sigma S \kappa_3 S} \text{ and } x_0 = \mu_S - \frac{3\sigma S}{\kappa_3 S}.$$

Noting that $a = \mu_S + k\sigma_S$, it leads to the approximation

$$E_{IG}(S - a)^+ = \sigma S E \left(\frac{S - \mu_S}{\sigma S} - k\right)^+ = \sigma S \int_k^\infty \frac{x - k}{\sqrt{2\pi (1 + \frac{1}{3} x \kappa_3 S)^3}} \exp \left[ -\frac{x^2}{2 (1 + \frac{3}{4} x \kappa_3 S)} \right] dx.$$
Using
\[
\frac{d}{dx} \left\{ \Phi \left( \frac{x}{\sqrt{1 + tx}} \right) - \exp \left( \frac{2}{t^2} \right) \Phi \left( \frac{x + \frac{2}{t}}{\sqrt{1 + tx}} \right) \right\} = \frac{1}{2\pi (1 + tx)^{3/2}} \exp \left[ -\frac{x^2}{2(1 + tx)} \right],
\]

\[
\frac{d}{dx} \left\{ \frac{2}{t} \exp \left( \frac{2}{t^2} \right) \Phi \left( \frac{x + \frac{2}{t}}{\sqrt{1 + tx}} \right) \right\} = \frac{1}{\sqrt{2\pi (1 + tx)^{3/2}}} \exp \left[ -\frac{x^2}{2(1 + tx)} \right],
\]

we obtain
\[
E_{IG}(S - a)^+ = \sigma_S \left\{ \left( k + \frac{6}{\kappa_{3S}} \right) \exp \left( \frac{18}{\kappa_{3S}^2} \right) \Phi \left( \frac{-k - \frac{6}{\kappa_{3S}}}{\sqrt{1 + \frac{1}{3}k\kappa_{3S}}} \right) - k\Phi \left( \frac{-k}{\sqrt{1 + \frac{1}{3}k\kappa_{3S}}} \right) \right\}.
\]

**G – IG approximation**

The G – IG approximation is a combination of the Gamma approximation and the IG approximation. Each of these approximations only uses the first three cumulants. A mixing parameter \( w \) can be chosen such that the kurtosis of \( S \) is fitted as well. The mixing parameter turns out to be

\[
w = w(\kappa_{3S}, \kappa_{4S}) = \frac{\kappa_{3S}^2 - \kappa_{4S}}{3\kappa_{3S}^2 - 3\kappa_{3S}^2} = 10 - \frac{6\kappa_{4S}}{\kappa_{3S}^2}.
\]

Hence, the G – IG approximation gives

\[
E_{G-IG}(S - a)^+ = w(\kappa_{3S}, \kappa_{4S}) E_G(S - a)^+ + [1 - w(\kappa_{3S}, \kappa_{4S})] E_{IG}(S - a)^+.
\]

**Remark A.1** In order that the weight \( w(\kappa_{3S}, \kappa_{4S}) \) in the G – IG approximation lies between 0 and 1 we should assume \( \frac{3}{2}\kappa_{3S}^2 \leq \kappa_{4S} \leq \frac{5}{2}\kappa_{3S}^2 \). Unfortunately, often this condition is not satisfied. However, we may use nevertheless the G – IG approximation (with \( w \) not in \((0, 1)\)) and simply consider it as an approximation. On the interval in which we are interested (\( s > a = \mu_S + k\sigma_S \) with \( 0 \leq k \leq 3 \)), often

\[
w(\kappa_{3S}, \kappa_{4S}) f_G \left( s - \mu_S + \frac{2\sigma_S}{\kappa_{3S}}; \left( \frac{2}{\kappa_{3S}} \right)^2, \frac{2}{\sigma_S\kappa_{3S}} \right)
\]

\[+ [1 - w(\kappa_{3S}, \kappa_{4S})] f_{IG} \left( s - \mu_S + \frac{3\sigma_S}{\kappa_{3S}}; \left( \frac{3}{\kappa_{3S}} \right)^2, \frac{3}{\sigma_S\kappa_{3S}} \right)
\]

behaves like a density. That is, it is positive on this interval. (In principle, in that case we could even extend it to a density, but note that we should also keep the first four moments of the approximation and those of \( S \) equal to each other and that makes it a little bit nasty; therefore we don’t bother and consider it simply as an approximation.) □

Next we present formulas for \( \mu_S, \sigma_S, \kappa_{3S} \) and \( \kappa_{4S} \).

**Formulas for \( \mu_S, \sigma_S, \kappa_{3S} \) and \( \kappa_{4S} \)**

So far, the approximations are in terms of \( \sigma_S, \kappa_{3S} \) and \( \kappa_{4S} \). It remains to link these quantities to the basic parameters \( \mu_G, \gamma_G, \mu_G, \gamma_G, \varepsilon \) and \( \lambda \). We start with expressions in case of general
\( C, G \) (with finite fourth moment), adding for the sake of completeness also \( \mu_S \):

\[
\begin{align*}
\mu_S &= \lambda \mu_C, \\
\sigma_S/(\sqrt{\lambda} \mu_C) &= \sqrt{1 + \gamma_C^2 - \epsilon + (1 + \gamma_C^2) \mu_G}, \\
\kappa_{3S}/(\lambda \mu_C^3) &= 1 + 3\gamma_C^2 + \kappa_{3C} \gamma_C^3 - \epsilon(1 + 3\gamma_C^2) + 3\epsilon \gamma_C^2 (1 + \gamma_C^2) \mu_G + \epsilon(1 + 3\gamma_C^2 + \kappa_{3G} \gamma_G^3) \mu_G^2, \\
\kappa_{4S}/(\lambda \mu_C^4) &= 1 + 6\gamma_C^2 + 4\kappa_{3C} \gamma_C^3 + (\kappa_{4C} + 3)\gamma_C^4 \\
&\quad - \epsilon(1 + 6\gamma_C^2 + 4\kappa_{3C} \gamma_C^3 + 3\gamma_G^2) + \epsilon(1 + \gamma_C^2)(4\kappa_{3C} \gamma_C^3 + 3\gamma_G^2) \mu_G \\
&\quad + 6\epsilon \gamma_C^2 (1 + \gamma_C^2 + \kappa_{3G} \gamma_G^3) \mu_G^2 \\
&\quad + \epsilon(1 + 6\gamma_C^2 + 4\kappa_{3G} \gamma_G^3 + (\kappa_{4G} + 3)\gamma_G^4) \mu_G^3, \\
\kappa_{3S} &= \kappa_{3S}'/\sigma_S^3, \\
\kappa_{4S} &= \kappa_{4S}'/\sigma_S^4.
\end{align*}
\]

So, \( \text{SLPapp}(\mu_C, \gamma_C, \mu_G, \gamma_G, \epsilon, \lambda) \) is obtained by inserting \( \sigma_S, \kappa_{3S} \) and \( \kappa_{4S} \) from (A1) into \( E_{C-G}(S-a)^+ \). It is easily seen that \( \kappa_{3S} \) and \( \kappa_{4S} \) do not depend on \( \mu_C \). Moreover, \( E_{C-G}(S-a)^+ \) is of the form \( \sigma_S h(\kappa_{3S}, \kappa_{4S}) \) and \( \sigma_S \) is of the form \( \mu_C h^*(\gamma_C, \mu_G, \gamma_G, \epsilon, \lambda) \). Hence, we get

\[
\text{SLPapp}(\mu_C, \gamma_C, \mu_G, \gamma_G, \epsilon, \lambda) = \mu_C \text{SLPapp}(1, \gamma_C, \mu_G, \gamma_G, \epsilon, \lambda).
\]

Assuming additionally \( G_k : P(L) \), we obtain

\[
\begin{align*}
\mu_S &= \lambda \mu_C, \\
\sigma_S/(\sqrt{\lambda} \mu_C) &= \sqrt{1 + \gamma_C^2 - \epsilon + (1 + \gamma_C^2) \mu_L}, \\
\kappa_{3S}/(\lambda \mu_C^3) &= 1 + 3\gamma_C^2 + \kappa_{3C} \gamma_C^3 - 3\epsilon(1 + \gamma_C^2)(1 + \gamma_L^2) \mu_L + \epsilon(1 + 3\gamma_C^2 + \kappa_{3L} \gamma_L^3) \mu_L^2, \\
\kappa_{4S}/(\lambda \mu_C^4) &= 1 + 6\gamma_C^2 + 4\kappa_{3C} \gamma_C^3 + (\kappa_{4C} + 3)\gamma_C^4 \\
&\quad + \epsilon(4(1 + 3\gamma_C^2 + \kappa_{3C} \gamma_C^3) + 3(1 + \gamma_C^2)^2)(1 + \gamma_L^2) \mu_L \\
&\quad + 6\epsilon(1 + \gamma_C^2)(1 + 3\gamma_L^2 + \kappa_{3L} \gamma_L^3) \mu_L^2 \\
&\quad + \epsilon(1 + 6\gamma_L^2 + 4\kappa_{3L} \gamma_L^3 + (\kappa_{4L} + 3)\gamma_L^4) \mu_L^3, \\
\kappa_{3S} &= \kappa_{3S}'/\sigma_S^3, \\
\kappa_{4S} &= \kappa_{4S}'/\sigma_S^4.
\end{align*}
\]

Hence, \( \text{SLPapp}(\mu_C, \gamma_C, \mu_L, \gamma_L, \epsilon, \lambda) \) is obtained by inserting \( \sigma_S, \kappa_{3S} \) and \( \kappa_{4S} \) from (A2) into \( E_{C-G}(S-a)^+ \).

In the particular case that \( C \) has a Gamma distribution we get \( \kappa_{3C} = 2\gamma_C \) and \( \kappa_{4C} = 6\gamma_C^2 \), implying

\[
1 + 3\gamma_C^2 + \kappa_{3C} \gamma_C^3 = (1 + \gamma_C^2)(1 + 2\gamma_C^2)
\]

and

\[
1 + 6\gamma_C^2 + 4\kappa_{3C} \gamma_C^3 + (\kappa_{4C} + 3)\gamma_C^4 = (1 + \gamma_C^2)(1 + 2\gamma_C^2)(1 + 3\gamma_C^2).
\]

When \( C \) has an Inverse Gaussian distribution we get \( \kappa_{3C} = 3\gamma_C \) and \( \kappa_{4C} = 15\gamma_C^2 \), implying

\[
1 + 3\gamma_C^2 + \gamma_C^3 \kappa_{3C} = 1 + 3\gamma_C^2 + 3\gamma_C^4
\]

and

\[
1 + 6\gamma_C^2 + 4\kappa_{3C} \gamma_C^3 + \gamma_C^3 (\kappa_{4C} + 3) = 1 + 6\gamma_C^2 + 15\gamma_C^4 + 15\gamma_C^6.
\]

When \( C \) has a Lognormal distribution we get \( \kappa_{3C} = \gamma_C (3 + \gamma_C^2) \) and \( \kappa_{4C} = \gamma_C^2 (16 + 15\gamma_C^2 + 6\gamma_C^4 + \gamma_C^6) \), implying

\[
1 + 3\gamma_C^2 + \gamma_C^2 \kappa_{3C} = (1 + \gamma_C^2)^3.
\]

(A5)
and
\[ 1 + 6\gamma_C^2 + 4\gamma_C^2\kappa_3C + \gamma_C^4(\kappa_4C + 3) = (1 + \gamma_C^2)^6. \] (A6)

**Remark A.2** Noting that
\[
1 + 3\gamma_C^2 + \kappa_3\gamma_C^2 = \mu_C^{-3}\nu_C^3,
\]
\[
1 + 6\gamma_C^2 + 4\kappa_3\gamma_C^3 + (\kappa_4C + 3)\gamma_C^4 = \mu_C^{-4}\nu_C^4,
\]
and that in case of a Gamma distribution we have for \( j = 1, 2, \ldots \)
\[
\mu_C^{-j}\nu_C^j = \prod_{i=1}^{j}(1 + i\gamma_C^2),
\]
while for the Lognormal distribution we get for \( j = 1, 2, \ldots \)
\[
\mu_C^{-j}\nu_C^j = (1 + \gamma_C^2)^{j(j-1)/2},
\]
the expressions (A3)–(A6) are easily seen. 

Obviously, similar expressions hold for \( L \), having a Gamma or an Inverse Gaussian distribution. In particular, when \( L \) has a Gamma distribution, we obtain
\[
\begin{align*}
\kappa_3G &= 2\gamma_G - \mu_G^{-1}\gamma_G^{-1}, \\
\kappa_4G &= 6\gamma_G^2 - 6\mu_G^{-1}\gamma_G^{-2} + \mu_G^{-2}\gamma_G^{-2}.
\end{align*}
\] (A7)

When \( C \) and \( L \) have a Gamma distribution, we obtain by combination of (A1) and (A7)
\[
\kappa_{3S}/(\lambda\mu_C^3) = (1 + \gamma_C^2)(1 + 2\gamma_C^2) + \varepsilon\mu_G^2(1 + \gamma_G^2)(1 + 2\gamma_G^2) \\
- \varepsilon(1 + 3\gamma_C^2) + \varepsilon(3\gamma_C^2(1 + \gamma_C^2) - \gamma_G^2)\mu_G
\]
and
\[
\kappa_{4S}/(\lambda\mu_C^4) = (1 + \gamma_C^2)(1 + 2\gamma_C^2)(1 + 3\gamma_C^2) \\
- \varepsilon(1 + 6\gamma_C^2 + 11\gamma_C^4) \\
+ \varepsilon\{(1 + \gamma_C^2)(1 + \gamma_G^2) - 6\gamma_C^2\gamma_G^2 + \gamma_G^4\}\mu_G \\
+ 2\varepsilon(3\gamma_C^2(1 + \gamma_G^2)(1 + 2\gamma_G^2) - \gamma_G^2(2 + 3\gamma_G^2))\mu_G \\
+ \varepsilon\{(1 + \gamma_C^2)(1 + 2\gamma_C^2)(1 + 3\gamma_C^2)\}\mu_G^3.
\]
