2	Cutting Edge Influence on Machining	Theory and Application	25
3	Titanium Alloy		
4	Juan Manuel Jauregui-Becker	A synthesis process comprehends a complex	26
5	Laboratoy of Design, Production and	combination of cognitive and mathematical	27
6	Management, University of Twente, Enschede,	mechanism (e.g., random generation, backward	28
7	The Netherlands	reasoning, abduction, case-based reasoning, and	29
		constraint-solving). Although no unified theory	30
		exists for explaining the nature of the synthesis	31
		process, the generally accepted FBS family of	32
8	Synonyms	frameworks allows for making some concrete	33
		statements on the nature of synthesis.	34
9	Combination; Creation; Integration		
		The FBS Model	35
10	Definition	FBS models a design artifact by distinguishing	36
		the following levels of object representation:	37
		function, behavior/state, and structure, as shown	38
11	Generally speaking, synthesis can be defined	in Fig. 1. The basis of the FBS model is that	39
12	as the composition or combination of parts –	the transition from function to structure is	40
13	building blocks, elements – to create a new	performed via the synthesis of physical behav-	41
14	whole product, artifact, technology, machine, or	iors. Therefore, behaviors allow characterizing	42
15	graphic, whose ruling behavior emerges from the	the implementation of a function. As many dif-	43
16	interaction of its constituents parts. In the context	ferent views of the FBS model have been devel-	44
17	of design, synthesis follows different definitions	oped and researched, the FBPSS model presented	45
18	(Chakrabarti 2002). The two most relevant to this	by Zhang et al (2005) serves as a unifying	46
19	work are “synthesis as designing” and “synthesis	framework for the different FBS schools of	47
20	as solution generation.” In the first definition,	thought. This model is based on the analysis and	48
21	synthesis is defined as an iterative process of	generalization of the Japanese (Umeda and	49
22	solution generation and solution evaluation. The	Tomiyama 1995), (Umeda and Tomiyama	50
23	second definition narrows its scope to that of	1997), European (Pahl et al. 2007), American	51
24	generation solutions.	(Chandrasekaran et al. 1993), and Australian	52
		(Gero and Kannengiesser 2004) schools of design	53
		theory and methodology.	54

55 The FBPSS model uses the following
56 definitions:

- 57 • **Structure:** Is a set of entities and relations
58 among entities connected in a meaningful
59 way. Entities are perceived in the form of
60 their attributes when the system is in
61 operation. For example, in Fig. 1 the structure
62 is represented by an electric motor and
63 a crank mechanism. Here, the two possible
64 entities (structures) are the lengths of the bars
65 L_1 and L_2 .
- 66 • **States:** Are quantities (numerical or categori-
67 cal) of the behavioral domain (e.g., heat
68 transfer, fluid dynamics, psychology). States
69 change with respect to time, implying the
70 dynamics of the system. For example, in
71 Fig. 1, the states of the structure are
72 represented by the distance L_0 between the
73 electric motor and the piston, the torque T of
74 the electric motor, or the displacement of the
75 pistons.
- 76 • **Principle:** Is the fundamental law that allows
77 the development of a quantitative relation of
78 the state variables. It governs behavior as the
79 relationships among a set of state variables.
80 For example, in Fig. 1, two possible principles
81 are electromagnetism ruling the operation of
82 the electric motor and solid mechanics ruling
83 the function of the crank mechanism.
- 84 • **Behavior:** Represents the response of
85 the structure when it receives stimuli. Since
86 the structure is represented by state and
87 structure variables, behaviors are quantified
88 by the values of these variables. In the case
89 presented in Fig. 1, the two behaviors are
90 *Generate torque* and *Convert torque into*
91 *force*.
- 92 • **Function:** It is about the usefulness of
93 a system. For example, in Fig. 1, one possible
94 function of this system is to compress gas.

95 Figure 2 shows how these definitions are
96 related. The relationship between state and struc-
97 ture is a one-to-many relation. The behavior is
98 produced as the combination of state sets
99 underlined by a given set of principles to
100 the structure. Behavior and function have
101 a many-to-many relation, which depends on the
102 context and usefulness of the structure.

Classification of Design According to Its Synthesis Process 103 104

105 Within this framework, one can classify
106 top-down steps aiming at determining the struc-
107 ture of an artifact given a functional representa-
108 tion as synthesis processes, while their back
109 reasoning counterpart of determining function
110 characteristics given a known structure as
111 analysis processes.

112 From this perspective, synthesis processes are Aut
113 classified into three groups according to the type
114 of representations:

- 115 • **Routine design:** One in which the space of
116 functions, behaviors, and structures are
117 known, and the problem consists of instantiat-
118 ing structure variables.
 - 119 • **Innovative design:** One in which the functions
120 and behaviors are known, and the design
121 consists of generating new structures that sat-
122 isfy them.
 - 123 • **Creative design:** One in which the functions
124 are known, and the problem consists in
125 determining the structures and behaviors
126 required to satisfy them.
- 127 Furthermore, as nature encompasses a vast
128 variety of behaviors (physical, chemical,
129 human, etc), synthesis processes can also be clas-
130 sified according to the types of behaviors being
131 targeted:
- 132 • **Engineering design:** Behaviors are character-
133 ized by principles stated in the laws of
134 physics. Depending on the discipline of
135 study, engineering design can be further
136 classified into mechanical, electrical,
137 chemical, geological, etc.
 - 138 • **Human-centered design:** Behaviors are char-
139 acterized by physiological, psychological, and
140 emotional human reactions. Two examples are
141 architectural design and industrial design.

Information Flow in Synthesis 142

143 Figure 3 shows a well-accepted model of the
144 design process (Schotborgh and van Houten
145 2012). According to this model, a candidate
146 solution is generated in a synthesis process. This
147 candidate solution is then analyzed to calculate
148 its performance. Finally, the evaluation process
149 assesses whether the solution is to be adjusted

^{Au2} 150 (path 1), rejected (path 2), or accepted (path 3). If
 151 necessary during the adjustment process,
 152 modifications (small) are made to the candidate
 153 solution, i.e., without changing the solution
 154 principle.

155 The flow of information through these pro-
 156 cesses can be classified into three types of infor-
 157 mation (Webber ; McMahon 1994): embodiment,
 158 scenario, and performance. Embodiment regards
 159 the information that describes the product being
 160 designed (e.g., its topology, size, and shape).
 161 Scenario regards the information that describes
 162 the flow of energy, mass, and signals the
 163 embodiment is exposed to. Finally, performance
 164 regards the information that determines how the
 165 embodiment behaves under a given scenario.

166 The relation between these three types of
 167 information varies according to the four
 168 processes of the design process model. In the
 169 synthesis process, embodiment information is
 170 generated (i.e., embodiment parameters are cho-
 171 sen and a candidate solution is formed) such that
 172 it meets certain performance parameters for
 173 a given scenario, as shown in Fig. 4b. Conversely,
 174 in the analysis process performance parameters
 175 are quantified or qualified for an embodiment
 176 undergoing a given scenario, as shown in
 177 Fig. 4a. In the evaluation subprocess, the gener-
 178 ated performance parameters are used to
 179 determine what follow-up action should be
 180 taken (paths 1–3). Finally, in the adjustment
 181 subprocess small changes to some embodiment
 182 parameters can be made in order to improve the
 183 performance of the candidate solution.
