Abstract: The band structure of a two-dimensional granular crystal composed of silicone rubber and polytetrafluoroethylene (PTFE) cylinders is investigated numerically. This system was previously shown to undergo a pattern transformation with uniaxial compression by Göncü *et al.* [Soft Matter 7, 2321 (2011)]. The dispersion relations of the crystal are computed at different levels of deformation to demonstrate the tunability of the band structure, which is strongly affected by the pattern transformation that induces new band gaps. Replacement of PTFE particles with rubber ones reveals that the change of the band structure is essentially governed by pattern transformation rather than particles' mechanical properties.

1. Introduction

Wave propagation in materials with periodic microstructures¹ has been studied extensively in the context of photonic and more recently phononic crystals.² The attenuation of electromagnetic, acoustic, or elastic waves in certain frequency ranges known as band gaps is an important feature of these materials that allows to use them as wave guides or filters.^{3,4}

Recent research has focused on the ability to control and tune the band gaps in phononic crystals. Several authors have reported⁵⁻⁷ the modification and tuning of the band structure of phononic crystals with external fields. On the other hand, 1D granular crystals (i.e., periodic chains of particles) attracted increasing attention due to their non-linear dynamics arising from tensionless contacts and non-linear interactions between particles. Their non-linear response can be tuned by changing the initial compression of the chain,⁸⁻¹⁰ leading to the design of tunable acoustic lenses¹¹ and phononic band gap materials.¹² Moreover, theoretical studies¹³ point out the possibility to control the band gaps of a periodic 2D granular crystal by introducing new periodicities in addition to existing ones.

Here we investigate numerically the propagation of elastic waves in a 2D bi-disperse granular crystal composed of large (and soft) silicone rubber and small (and stiff) polytetrafluoroethylene (PTFE) cylinders.¹⁴ In the undeformed crystal, particles are placed on two embedded square lattices [Fig. 1(a)]. When the system is uniaxially compressed, particles rearrange into a new periodic pattern¹⁴ as illustrated in Fig. 1(b). We will show that the pattern transformation triggered by deformation can be effectively used to tune and transform the band gaps of the structure. The crystal under consideration consists of 5 mm radius silicone rubber and 2.5 mm radius PTFE particles. Material properties of silicone rubber are characterized by density $\rho_r = 1.05 \times 10^3$ kg/m³, Young's modulus $E_r = 360$ kPa, shear modulus $G_r = 120$ kPa, and longitudinal speed of sound $c_r^{l0} = 77.1$ m/s, while for PTFE one has $\rho_t = 2.15 \times 10^3$ kg/m³, $E_t = 1$ GPa, $G_t = 336.2$ MPa, and $c_t^{l0} = 1350$ m/s.

(c) Sketch of two particles in contact showing displacements and the geometric overlap δ . (d) Normal contact force as a function of the overlap for a pair of (5 mm) silicone rubber and (2.5 mm) PTFE particles.

2. Modeling

Particles are modeled as 2D disks in a way similar to soft-particle molecular dynamics (MD).¹⁵ The forces in the normal contact direction are described by a non-linear contact force law as function of the geometric overlap δ [see Figs. 1(c) and 1(d)]:

$$f(\delta) = k_1\delta + k_2\delta^\alpha. \tag{1}$$

The parameters k_1 , k_2 , and α depend on the radii and mechanical properties of the particles in contact and their numerical values (listed in Table I) are determined by fitting Eq. (1) to force-displacement data obtained from finite element method (FEM) simulations of various contacts. For the sake of simplicity, tangential contact forces are modeled with a linear spring of stiffness k_t . Because a parametric study reveals that the magnitude of the tangential stiffness does not have a significant effect on the pattern transformation, here we assume $k_t/k_n = 0.1481$ based on an estimate by Luding,¹⁶ with the linearized normal stiffness, k_n , defined in the following text.

Table 1. Numerical values of contact force parameters k_1 , k_2 , and α for pairs of silicone rubber (SR) and PTFE particles.

	k_1 (N/mm)	k_2 (N/mm $^\alpha$)	α
SR ^a - SR ^a	1.3459	0.1264	2.9793
SR ^a - PTFE ^b	2.5197	0.2217	3.3028
PTFE ^b - PTFE ^b	3468	1706.9	2.8147
SR ^a - SR ^b	1.3992	0.4921	3.1357
SR ^b - SR ^b	1.1018	0.4372	2.3877

^a $R = 5$ mm.

^b $R = 2.5$ mm.

The propagation of elastic waves in infinite periodic lattices has been studied using techniques based on structural mechanics and FEM.^{17–19} Following this approach, two contacting particles p and q can be viewed as a finite element²⁰ with the nodes located at the particle centers. Their interaction is then characterized by a stiffness matrix \mathbf{K}^{pq} , which relates the displacements and orientations [Fig. 1(c)] $\mathbf{U}^{pq} = [u_x^p, u_y^p, \theta^p, u_x^q, u_y^q, \theta^q]^T$ to the forces and torques acting on the particle centers $\mathbf{F}^{pq} = [f_x^p, f_y^p, \tau^p, f_x^q, f_y^q, \tau^q]^T$ such that $\mathbf{F}^{pq} = \mathbf{K}^{pq}\mathbf{U}^{pq}$ in the local coordinate system of the contact defined by the normal $\hat{\mathbf{n}}$ and tangent $\hat{\mathbf{s}}$, see Fig. 1(c). For a contact characterized by linear stiffnesses k_n and k_t in normal and tangential direction, respectively, \mathbf{K}^{pq} is given by²⁰

$$\mathbf{K}^{pq} = \begin{bmatrix} k_n & 0 & 0 & -k_n & 0 & 0 \\ 0 & k_t & k_t R^p & 0 & -k_t & k_t R^q \\ 0 & k_t R^p & k_t R^p R^p & 0 & k_t R^p & k_t R^p R^q \\ -k_n & 0 & 0 & k_n & 0 & 0 \\ 0 & -k_t & -k_t R^p & 0 & -k_t & -k_t R^q \\ 0 & k_t R^q & k_t R^p R^p & 0 & -k_t R^q & k_t R^q R^q \end{bmatrix}, \quad (2)$$

where R^p and R^q are the radii of the particles. Note that because we consider small amplitude perturbations of statically compressed particles with initial overlap δ_0 , Eq. (1) can be linearized as

$$f(\delta) \approx f(\delta_0) + k_n(\delta - \delta_0), \quad (3)$$

where $k_n = df/d\delta|_{\delta=\delta_0}$ is the linearized contact stiffness.

To compute the dispersion relation, we consider an infinite crystal and solve the equations of motion for its periodic unit cell, disregarding effects due to finite systems with walls. Free harmonic oscillations are assumed, and periodic boundary conditions are applied using Bloch's theorem.^{17,19} The final form of the equation of motion is of a generalized eigenvalue problem:

$$[-\omega^2 \mathbf{M} + \mathbf{K}]\mathbf{U} = 0, \quad (4)$$

where ω is the radial frequency of the oscillations. \mathbf{M} and \mathbf{U} are the mass matrix and displacement vector of the unit cell, respectively, and the global stiffness matrix \mathbf{K} is assembled from the contributions of individual contacts according to the classical finite element assembly procedure. Note that although this approach assumes a fixed contact network and sliding between particles (i.e., friction) is neglected, it is still valid for this study because small amplitude perturbations superimposed to a given (finite) state of deformation are considered.

3. Results

The dispersion diagrams for the 2D granular crystal at different levels of macroscopic nominal strain are provided in Fig. 2, clearly revealing the transformation of the band gaps with deformation. In the undeformed configuration, the periodic unit cell of the crystal consists of a pair of rubber and PTFE particles arranged on a square lattice [Fig. 2(d)], and the structure possesses a phononic band gap for nondimensional frequencies $0.590 < \tilde{\omega} < 0.823$, where $\tilde{\omega} = \omega A / (2\pi c_r^{(0)})$ with $A = (\|\mathbf{t}_1\| + \|\mathbf{t}_2\|) / 2$, \mathbf{t}_1 and \mathbf{t}_2 being the lattice vectors.

At 15% compression, the new pattern starts to emerge and the crystal has a unit cell composed of two pairs of rubber and PTFE particles [Fig. 2(e)]. The structural transformation alters the dispersion relation of the crystal. Remarkably, a new band gap is open and the structure has now two band gaps at $0.141 < \tilde{\omega} < 0.419$ and $0.712 < \tilde{\omega} < 0.778$ [Fig. 2(b)].

Fig. 2. (Color online) Top: Dispersion curves of the bi-disperse granular crystal composed of large rubber (5 mm) and small PTFE (2.5 mm) particles with tangential stiffness $k_t = 0.1481 \times k_n$ at (a) 0%, (b) 15%, and (c) 25% uniaxial compression. The vertical axes represent the non-dimensional frequencies $\tilde{\omega} = \omega A / (2\pi c_r^0)$ with $A = (\|t_1\| + \|t_2\|) / 2$. Bottom: Unit cells, lattice vectors t_1 and t_2 and the first Brillouin zones of the crystal at (d) 0%, (e) 15%, and (f) 25% uniaxial compression. The shaded areas indicate the irreducible parts of the Brillouin zones.

The transformation is complete when the PTFE particles touch [Fig. 2(f)]. Figure 2(c) shows the corresponding band structure of the patterned crystal at 25% compression. The stiff contacts between PTFE particles lead to transmission and band gaps at much higher frequencies. At this level of deformation, the structure is characterized by three band gaps in the intervals $0.142 < \tilde{\omega} < 0.545$, $0.885 < \tilde{\omega} < 3.557$ [partially shown in Fig. 2(c)] and $3.557 < \tilde{\omega} < 19.417$ [not shown in Fig. 2(c)].

Fig. 3. Dispersion relation of a soft granular crystal made of rubber particles in the (a) undeformed and (b) patterned state (at 25% compression) with $k_t/k_n = 0.1481$. Evolution of the band gaps in the (c) undeformed and (d) patterned [band gaps marked by I, II, and III in (b)] soft granular crystal as function of the stiffness ratio k_t/k_n .

Our previous study suggested that the qualitative nature of the pattern transformation mainly depends on the size ratio of the particles.¹⁴ The characteristic pattern was observed to form only when the size ratio $\chi = R_{\text{small}}/R_{\text{large}}$ of the small and large particles is in the range $\sqrt{2} - 1 \leq \chi \leq 0.637$, and the transformation was found to be practically reversible around $\chi \approx 0.5$. Both FEM and MD simulations showed that the material properties of the particles do not play an essential role in the pattern transformation.¹⁴ To investigate the effect of the material properties on the band gaps, we consider a crystal made entirely of rubber, replacing the 2.5 mm radius PTFE particles with rubber ones of the same size. The dispersion curves of the structure in the undeformed configuration and at 25% compression after pattern transformation are shown in Figs. 3(a) and 3(b), respectively, showing that the band structure is not affected qualitatively by the replacement. However, (i) the band structure is lowered due to the softer particles [Fig. 3(a)] and is significantly lowered at large strains [Fig. 3(b)] due to the absence of stiff contacts, (ii) the band gap of the undeformed rubber-rubber crystal [Fig. 3(a)] is wider than before [Fig. 2(a)], and (iii) in the deformed state of the soft structure, an additional narrow band gap is present at low frequencies.

Finally, we investigate the effect of the tangential stiffness of the contacts on the band structure by varying the ratio k_t/k_n in the crystal composed of rubber-rubber particles because the tangential stiffness depends on the material properties of the particles and can change when the crystal is further processed (e.g., by sintering²¹). Increasing tangential stiffness k_t leads to higher frequencies but does not influence the pattern transformation. Focusing on the phononic properties, Figs. 3(c) and 3(d) show that both width and frequency of the band gaps increase with increasing tangential stiffness.

4. Discussion and conclusion

In conclusion, we have shown that the band structure of a 2D bi-disperse soft granular crystal composed of large and small particles placed on two embedded square lattices can be modified considerably by deformation. The structural transformation triggered by compression leads to the opening of new band gaps. When translated to real frequencies, the band gap marked with I in Fig. 3(b) falls between 5015.8 and 5706.5 Hz; this indicates that the crystal could be used as a tunable filter in the audible range, which makes such crystals promising candidates for applications in acoustics when tunable band gap materials are needed. In this study, we focused on the dispersion relations of infinite regularly patterned granular crystals neglecting damping. Nevertheless, band gaps have been also detected in finite size, viscous systems.¹⁸ Therefore we expect our results to hold also for the finite size, dissipative versions of the granular crystals studied here.
